Supplemental Figure 1. Scatter plot of neuropsychological assessment test scores. (A) Mini-Mental State Examination (MMSE) and (B) Consortium to Establish a Registry for Alzheimer’s Disease-Neuropsychological Assessment Battery (CERAD-NAB) total scores were determined at baseline and one week after surgery. Test results of patients presenting with and without postoperative cognitive dysfunction (POCD) are shown. Postoperative MMSE and CERAD-NAB total scores were lower in patients diagnosed with POCD ($P = 0.007$ and $P = 0.002$, respectively).
