

Supplemental Figure 12. Portal venous air from mesenteric ischemia. Hemodynamic instability in an 85-year-old patient after removal of an intra-aortic balloon pump 2 days after cardiac surgery associated with normal cerebral oximetry values but elevated lactate. (A,B) Upon examination of the liver using transesophageal echocardiography, air was present in the portal vein (arrow). (C, D) Computed tomography revealed air in the left lobe of the liver, most likely resulting from mesenteric ischemia.
