

A. Minute ventilation

B. Breathing frequency

C. Tidal volume

D. I:E ratio

E. EF50

F. Body weight

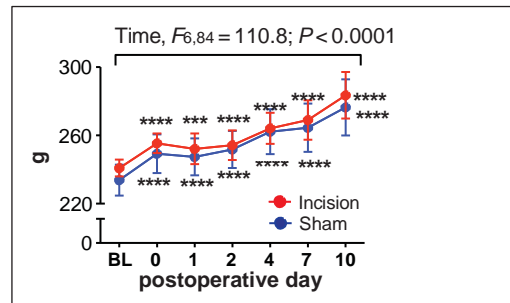

Figure S2. Raw (non-normalized) data for the Protocol C, the effect of upper abdominal incision vs. sham incision on the ventilatory parameters. **(A)** Minute ventilation of the Incision group after the surgery, on POD 0 through POD 10, was significantly lower compared with baseline (POD 0: $P = 0.0001$; POD 1: $P = 0.0006$; POD 2: $P = 0.0070$; POD 4: $P = 0.0010$; POD 7: $P = 0.0015$; POD 10: $P = 0.0003$). On the other hand, there was no statistical difference in minute ventilation of the Sham group throughout the testing period. **(B)** Breathing frequency of the Incision group on POD 0 through POD 10 was significantly lower compared to baseline (POD 0: $P < 0.0001$; POD 1: $P < 0.0001$; POD 2: $P = 0.0072$; POD 4: $P = 0.0019$; POD 7: $P = 0.0002$; POD 10: $P = 0.0022$). The mean breathing frequency values of the Sham group were not different throughout the testing period. **(C)** For tidal volume, there was no significant main effect or interaction. **(D)** Inspiratory-to-expiratory time ratio (I:E ratio) of the Incision group was lower compared with baseline on POD 0 through POD 7 (POD 0: $P < 0.0001$; POD 1: $P < 0.0001$; POD 4: $P = 0.0054$; POD 7: $P = 0.0017$); I:E ratio of the Sham group was not significantly different throughout the testing period. **(E)** For expiratory flow at 50% expired volume (EF50), there was no significant main effect or interaction. **(F)** Body weight on POD 0 through POD 10 were significantly greater compared with baseline in both the Incision and the Sham groups. Data are presented as mean \pm SD. $N = 8$ per group. $**P < 0.01$; $***P < 0.001$; $****P < 0.0001$ vs. Baseline, and $\dagger P < 0.05$; $\dagger\dagger P < 0.001$; $\dagger\dagger\dagger P < 0.0001$ vs. Sham by two-way ANOVA with repeated measured in one factor, followed by Sidak's multiple comparison tests. BL = baseline.
