

In Memoriam

Raymond Carhart, who was to be a guest speaker at the A.A.S. annual meeting November 5, died suddenly in Chicago on October 2, 1975. It was he who attended the birth of Audiology, nurtured its adolescence, and by personal example led it into respectable maturity. The Society mourns the passing of this most distinguished audiologist and elder statesman.

Glorig Passes Reins

Ward Named President

Aram Glorig, founder and first president of the American Audiology Society, retired as president of the Society at the

November meeting in San Francisco. He passed the reins of the society to another dynamic president, W. Dixon

Ward.

CORTI'S ORGAN takes this opportunity to honor Aram for his leadership in organizing the American Audiology Society. Almost single-handedly he conceived an organization that would permit all people concerned with human hearing to meet in a common forum. He was impatient with societies that allowed only those of one discipline to have a dialogue with each other on hearing problems, that excluded concerned non-professionals, and that had tunnel vision in the area of hearing function. He served as president and long-time board member of the International Audiology Society where he envisioned bringing the same kind of organization to the United States.

Whatever the American Audiology Society becomes it will owe its future success to the vision and determination of Aram Glorig.

'Rehabilitation through Research' Theme of Annual A.A.S. Meeting

The 1975 meeting of the American Audiology Society was held in conjunction with the Acoustical Society of America meeting in San Francisco, November 3. Four excellent speakers delivered papers to some 60 attending members on the theme of "Rehabilitation through Research". Owen Black M.D., Pittsburgh Eye and Ear Hospital, "New Instrumentation for Vestibular Studies"; Norma Hopkinson, Ph.D., Pittsburgh Eye and Ear Hospital, "Relevance of Clinical Research to Rehabilitation of Persons with Auditory Disorders"; Robert Houde, Ph.D. and Donald

Johnson, Ph.D., National Technical Institute for the Deaf, (Rochester, New York), "Visual Aids for Speech Training of the Deaf"; and Nelson Y.S. Kiang, Ph.D., Massachusetts Eye and Ear Infirmary, "Electrocochleography". (These papers are discussed further under "Abstracts of Papers".)

The program was arranged by Bruce Graham, who served as chairman for the meeting.

Election of officers followed the program, with the new officers and Board members (See Minutes of the Executive Committee of The American Audi-

ology Society, Pg. 3)

Those who attended the Acoustical Society's meetings were in agreement on the highlight of the meeting. It was a special report of the Committee on the Watergate Tapes. This group of outstanding experts, headed by Richard Bolt, described how they determined that the tape had been deliberately tampered with. For example, they were able to demonstrate definitely that the "18 minute gap" that had recorded speech underneath and the buing tone that was superimposed on it. They also determined that the 18 minute

section had first been erased and then the buzz had been superimposed. The tape they were given was shown to be the

original. The report sounded like a modern-day Sherlock Holmes episode, with cloak and dagger overtones.

Ranney Outlines

Research Grants

J. Buckminster Ranney is Executive Secretary of the Communicative Disorders Review Committee of the National Institute of Neurological and Communicative Disorders and Stroke (NINCDS). He has furnished a description of the various types of grants now available from NINCDS.

The National Institute of Neurological and Communicative Disorders and Stroke provides research grant support for problem areas of significance by means of research project grants, research program projects, clinical research centers and outpatient clinical research units. The Research Project Grant is an award to an institution in the name of an investigator for a discrete, circumscribed research investigation. The Research Program

Project Grant is an award to an institution in the name of a program director for a period of initial support of a team of investigators participating in a broadly based multidisciplinary or multifaceted program of basic research which has significance in the communicative sciences. The Clinical Research Center Grant is an award to an institution in the name of a program director for investigations focused upon a specific disease or a group of diseases or disorders of human communication. The Outpatient Clinical Research Unit Grant is an award to an institution in the name of a principal investigator to assist in the establishment, improvement and support of a stable outpatient research environment in which clinical research studies of ambulatory populations may be conducted.

News About Members

GEORGE E. LYNN (Wayne State University School of Medicine) traveled to Peru this summer to study the temporal bones of mummies of the Inca and Pre-Inca Indians. George has previously reported on the temporal bones of Egyptian mummies, and will make comparisons of the ears of these ancient peoples, as part of a continuing study of ancient human populations. So far he reports finding little evidence of

ear disease among the ancient Peruvians.

STANLEY ZERLIN AND RALPH NAUNTON have an ongoing study of the cochlear microphonic recorded from the human promontory and its relation to hair cell dysfunction. They recently presented a short course on Electrocochleography at the 1975 meeting of the American Speech and Hearing

Association. Stan has been elected an Associate fellow of the American Academy of Ophthalmology and Otolaryngology.

WILLIAM F. RINTLEMANN, formerly Professor and Director of Audiology at Michigan State University was appointed

an editorial

If you are thinking that the change of name to CORTI'S ORGAN has been made to attract attention and stimulate interest, you are quite right. What better name for the house organ of a society devoted to hearing? We unabashedly preempt it for the AUDIONEWS.

Ye Editor and Ye Associate Editor have great ambitions for this house organ. In future editions we will solicit pre-publication abstracts of outstanding scientific articles; we will encourage brief preliminary reports of on-going research projects that otherwise might not be published for years; and we will attempt to cover up-to-date news of relevant (and irrelevant) activities of our members. To do this we will needle members to provide these items from time to time. Please establish a mental set to report to us the kinds of activities that will be of interest to our members. Help CORTI'S ORGAN hear, y'all!

ACKNOWLEDGMENT

The Editors wish to acknowledge the great contribution of Robert Briskey, who was the first editor and guiding spirit of AUDIONEWS. He faithfully put out the house organ during the first two years of the existence of A.A.S. Due to recent illness he was forced to relinquish the editorship, but we are delighted to learn that he has recovered and is back at work at the Beltone shop. Our sincere appreciation and best wishes go to Bob.

New Tinnitus Group Formed

A new society has been formed to study the causes and prevention of tinnitus. Called the American Tinnitus Association (ATA), it was founded by Charles Unice, a doctor who suffers himself from tinnitus, and by Jack Vernon and David DeWeese of Portland, Oregon. Robert Hochs of Oregon, past president of the National Association of Earmold Laboratories, has also been active in organizing the society.

The association is dependent on funding from ATA memberships. Further information may be obtained from: American Tinnitus Association, Development Office, University of Oregon Health Sciences Center, 3181 S.W. San Jackson Park Road, Portland, Oregon 97201.

Lybarger Reports on Hearing Aid Standards

An ANSI Working Group, S3-48 has been working for a year and a half on a specification standard for hearing aids. A.A.S. member Sam Lybarger is chairman of the committee. The work was undertaken at the request of the Food and Drug Administration, who plan to consider hearing aids as a "medical device".

Lybarger reports that the F.D.A. may adopt most of the provisions of the agreed-upon standard in their own regulatory standard. This would require that manufacturers maintain the performance of a given model hearing aid to within specified tolerances of the characteristics stated by the manufacturer for the model. The ANSI committee proposed standard is approaching completion and will be submitted to S-3 members for final review in the immediate future.

Lybarger has provided an outline of the tests being considered in this proposal standard, along with examples of frequency response curves and tolerance templates. (See accompanying chart and figures).

CONDENSED OUTLINE OF TESTS BEING CONSIDERED IN PROPOSED ANSI STANDARD FOR h.a. SPECIFICATION.

Characteristic	Input SPL dB re 20 µPa	Frequency Hz	Gain Control Setting	Presentation	Tolerance Requirements
SSPL90 (Saturation)	90	200-5000	Full on	Curve	Basic test equipment tolerance
Maximum SSPL90	90	Any frequency between 200 & 5000	Full on	Number (dB)	Mfr. to state max. value for model
Average SSPL90	90	1000, 1600 2500	Full on	Number (dB) (3-freq. average)	± 4 dB
Average full-on gain	60 or 50 (State which) 50 for AGC	1000, 1600 2500	Full on	Number (dB) (3-freq. average)	± 5 dB
Reference Test Gain Control Position*	60	1000, 1600 2500	Set gain control back to give output SPL 17 dB less than average SSPL 90, or full on for low gain aids		17 ± 1 dB
Frequency Response	60	200-5000 or to -20 dB below 3-freq. avg.	Reference test position	Curve	Low band ± 4 dB High band ± 6 dB
Total Harmonic Distortion	70	500, 800, 1600	Reference test position	Number (%)	Mfr. to state max. values for model
Equivalent Input Noise Level, L _n	60	1000, 1600 2500 (Avg. to get L _{av})	Reference test position	Number (dB) L _n =L ₂ -(L _{av} -60) **	Mfr. to state max. value for model
Telephone Pickup (Induction coil)	10 mA/m rms magnetic field	1000	Full on	Number (dB)	Within ± 6 dB of mfrs. specified value
Battery Current	70	1000	Reference test	Number (mA)	Not to exceed mfrs. specified maximum for the model
Input-Output Curves (AGC only)	50 to 90	2000	Full on	Curve Input=abscissa Output=ordinate	Match at 70 dB input then to be within +4 dB of specified
Attack and Release times (AGC only)	Abrupt 55 to 80; 80 to 55	2000	Full on	Numbers (ms)	To be within values specified by mfr.

* Reference test gain control position for AGC aids is full on.

** L₂ is the noise reading in the coupler with the input signal turned off.

10-2-75 SFL

HF-average SSPL90 - $(S_1 + S_2 + S_3) / 3$.

Reference test gain control position is determined by:

$(S_1 + S_2 + S_3) / 3 - (R_1 + R_2 + R_3) / 3 - 17 \text{ dB}$.

EXAMPLE OF SSPL90 AND FREQUENCY RESPONSE CURVES

FIGURE 1

Horizontal line H is 20 dB below the average of the 1000, 1600 and 2500 Hz levels on the specified response curve. In use, the template must be kept square with the graph of the measured curve, but may be adjusted vertically any amount and horizontally up to ± 10% in frequency. Lines on the template at 900 and 1100 Hz show the maximum allowable horizontal movement referred to the 1000 Hz ordinate on the measured curve. After adjustment of the template, the measured curve must lie between the upper and lower limits on the template.

EXAMPLE OF CONSTRUCTION OF TOLERANCE TEMPLATE FOR FREQUENCY RESPONSE CURVE

FIGURE 2

Outstanding Workshops Scheduled for Spring

Two unusually outstanding Workshops will be held this spring, and one this summer, featuring noted International and American authorities. The spring Workshops are back-to-back in March and will present a difficult choice to Otolaryngologists and Audiologists.

SHAMBAUGH FIFTH INTERNATIONAL WORKSHOP

Chicago
February 29-March 5

At this conference "new and current techniques of cochlear and vestibular testing, modern tympanoplastic techniques, methods of treating fluctuant hearing loss, and the medical and surgical management of otospongiosis of the cochlear capsule and stapes footplate will be discussed by world recognized authorities. A faculty of 83 leaders of modern microsurgery of the ear will present their views in scheduled talks and round table discussions. Relaxations with films covering the program topics will conclude each day.

Among the invited speakers will be A.A.S. members Richard J. Bellucci, Ralph Caparosa, D. Thane Cody, J. Brown Farrior, Michael Glasscock, Wiley Harrison, Jack Hough, Howard P. House, William F. House, F.H. Linthicum, Cary Moon, P. Douglas Noffsinger, Jerry Nothorn, W. Hugh Powers, Jack Pulec, Wallace Rubin, Maurice Schiff, John Shea, Mansfield Smith, James Snow and William H. Wilson.

National Advisory Board Named for Kendall Demonstration Elementary School

WASHINGTON, D.C.— A nine-member National Advisory Board has been named to assist the Kendall Demonstration Elementary School in developing and implementing innovative program designs for deaf youngsters.

Appointed by the Gallaudet Board of Directors, the group's purpose is to advise the President of the College, the Dean of Pre-College Programs, and the Director of Kendall School on directions in which KDES, as a federally-funded facility, should move to achieve significant program advances in education of the deaf.

The nine include: Dr. Robert K. Lennan, Dr. Harvey J. Corson, Dr. Luther Robinson, Dr. Keith Turner, Dr. Roy Stelle, Dr. McCay Vernon, Dr. Donald Calvert, Dr. Robin Prescott, and Dr. Richard Kretschmer.

TENTH COLORADO MEDICAL AUDIOLOGY WORKSHOP

Vail, March 6-13

The theme of this conference is the EAR, in all its otologic and audiologic manifestations. Michel Portmann, M.D., of Bordeaux, France, will be the honored guest. Well known otolaryngologists and audiologists will discuss neuro-otology, Sudden Deafness, Middle Ear Surgery, Vestibular Problems, Diagnostic Audiology, Occupational Hearing Programs, Acoustic Impedance Measures, Serous Otitis Media

and Hearing Aids.

Among the invited speakers will be A.A.S. members Charles I. Berlin, Michael E. Glasscock, David M. Lipscomb, Mansfield Smith, Lloyd Storrs, LaVonne Bergstrom, Leo Doerfler, Aram Glorig, William G. Hemenway, Geary McCandless, Ross Roeser and F. Blair Simmons. Dr. Jorgen Holmquist of Sweden will discuss impedance measurements and tubal function.

The featured lectures of this Workshop will be presented for publication in the Journal of the American Audiology Society.

SYMPOSIUM ON CHILDHOOD DEAFNESS Mt. Pleasant, Michigan June 15-18

As indicated in the title, this symposium will center on deafness in children. Presentation areas include etiological factors, pathology of childhood deafness, identification and assessment and management/intervention.

Among the invited speakers will be several A.A.S. members.

Official Minutes

The Executive Committee of American Audiology Society

Date: November 1, 1975
Time: 1:15 p.m.
Place: Jack Tarr Hotel
San Francisco, California

Members in Attendance:

Charles Berlin, Ph.D.
Meyer Fox, M.D.
Aram Glorig, M.D.
Bruce Graham, Ph.D.
Fred Linthicum, M.D.
Sam Lybarger, B.S.
Geary McCandless, Ph.D.
Ralph Naughton, M.D.
Ross J. Roeser, Ph.D.
F. Dixon Ward, Ph.D.

The meeting was called to order by the President, Aram Glorig.

Because there are key persons involved in conducting the business of the Society, conducting the annual meeting, and publishing the Journal; and because it is critical that these key individuals attend the annual Executive Committee Meeting, the following motion was made: "The Society will provide reasonable expenses above other reimbursement, if any, for the President, Secretary/Treasurer, Journal Editor, and Program Chairman to attend the annual meeting of the Society effective January, 1976 depending on availability of funds." (Passed)

In view of his significant contribution to the field of audiology, and his support of the American Audiology Society, a motion was made to create a Raymond Carhart Memorial Lectureship and Award. A subcommittee was appointed to make recommendations for implementation of this lectureship. Chuck Berlin was appointed Chairman, Geary McCandless and Sam Lybarger were appointed members. Aram Glorig indicated that he would contact Mrs. Carhart for her approval.

The results of election were announced by the Secretary/Treasurer. Those persons elected to the Executive Committee are:

Special Event

The XIII International Congress of Audiology will meet in Florence Italy, October 18-21, 1976. Two group flights are being planned, one for one week's stay and the other for two weeks (See announcement enclosed). Interested persons may fill out the accompanying form for further information. Registration materials for the Congress may be obtained by writing to: Fondazione Giovanni Lorenzini, Via Giovanni Lorenzini, 2, 20139 Milan, Italy.

[See Page 4 and 5]

Current Abstracts

(This month we have singled out the September 1975 issue of S/N - Sound and Vibration, which contains articles relevant to Occupational Noise.)

Effects of Noise on Human Performance, by Jay M. Finkelman, Ph.D., City University of New York.

This investigation viewed the individual as a communications channel and evaluated the effect of noise on performance using a delayed digit recall subsidiary task measure derived from information theory. Performance did not deteriorate until channel capacity was exceeded. Prior research may not have detected performance degradation because measurement techniques lacked sensitivity with respect to total information processing load.

In essence, the reported investigation has demonstrated the potential for performance degradation at physiologically safe levels of noise. If the individual is already loaded to the limits of his channel capacity by existing task and environmental demands (not including noise), the capacity that is usurped by the noise, will, in fact, result in performance degradation.

Another criterion for noise regulation is being proposed in this article. It is the information processing cost of noise adaptation and, through extrapolation, the performance degradation resulting from environmental noise under high ambient information processing load conditions.

Contribution of Animal Research to Noise Exposure Criteria, by Donald Henderson, Ph.D. and Roger P. Hamernik, Ph.D., State University of New York, Syracuse.

Two shortcomings of the present noise exposure criteria are illustrated by animal experi-

mentation. First, pure-tone thresholds do not necessarily reflect the status of the sensory cells in the ear; second, combinations of safe impulse and safe continuous noise may produce severe hearing losses and cochlear damage.

Chinchilla recovered normal hearing levels after 30 days following exposure to 50 noise impulses of 158 dB peak equivalent SPL. However, all animals in the group had serious losses of outer hair cells in the middle of the cochlea, i.e. 4-6 mm of the sensory epithelium of the cochlea was devoid of outer hair cells. Another experiment demonstrated that a combination of impulse and continuous noise exposure produced greater damage to hair cells than either noise exposure alone.

Performance of Earphone Enclosures for Threshold Audiometry, by Ross J. Roeser, Ph.D., Janice Seidel, M.A. and Aram Glorig, M.D.

Pure tone Bekesy thresholds were recorded from 12 normal hearing subjects at octave frequencies ranging from 250 Hz through 8 kHz and at 6 kHz. The same TDH-39 driver was mounted in: a standard (MX-41/AR) cushion, an Auraldome (Model AR-100R) and an Audiocup (Amplivox). Thresholds were recorded in quiet and in the presence of broad and narrow band noise presented at 40, 50 and 60 dB SPL. In the quiet condition the use of the Auraldome resulted in thresholds that were less sensitive than either the Nx-41/AR or the Audiocup. Thresholds obtained while using the Auraldome were not appreciably different from thresholds using the Mx-41/AR in the presence of sound-field noise. Thresholds for the Audiocup in noise were discernably better than the Auraldome or MX-41/AR.

Jamie T. Benitez, M.D.
Leo Doerfler, Ph.D.
David Dolowitz, M.D.
Gilbert R. Herer, Ph.D.
Norma T. Hopkinson, Ph.D.
Hiroshi Shimizu, M.D.
Laura Ann Wilbur, Ph.D.

It was suggested that safeguards be implemented in the future to keep an equitable representation of the disciplines involved on the Executive Committee.

Fred Linthicum reported on the membership committee. Four regional membership chairmen were appointed from otolaryngology: Mansfield Smith, M.D., - Western Region, Wiley Harrison, M.D., - Central Region, Joseph Sataloff, M.D., - Eastern Region and Jim Spenser, M.D., - Southern Region. The Regional Chairmen for audiology have not yet been appointed and will be reported at a later date. Sam Lybarger indicated that he would contact members of the hearing aid industry and other disciplines. The sole purpose of the membership committee is to disseminate information regarding the Society and recruit members.

In accordance with last year's minutes, the following motion was made, "The Executive Committee approves the actions of the President of the American Audiology Society in approaching the International Audiology Society requesting that the American Audiology Society be made the recognized representative to the International Audiology Society from the United States. (Motion Passed)

Only two numbers of the Journal were issued in 1975. Membership dues were based on six issues. It was recommended by the Finance Committee that members paying dues in 1975 be given credit for Journals not received. Pending discussion with Williams & Wilkins this pro-

AMERICAN AUDIOLOGY SOCIETY EUROPEAN STUDY TOUR

Available to Members and Their Immediate Family

OCTOBER, 1976

ALL INCLUSIVE TOUR INCLUDES:

- HIGHLIGHTS POINTS OF PROFESSIONAL INTEREST INCLUDING THE HEARING AID INSTITUTE, LUBECK, GERMANY & THE XIII INTERNATIONAL CONGRESS OF AUDIOLOGY, FLORENCE, ITALY.
- AIR FARE & GROUND ARRANGEMENTS.
- DELUXE HOTELS.
- SUPERIOR CONTINENTAL BREAKFAST INCLUDED EVERY DAY. LUNCHES & DINNERS AS PER FINAL ITINERARY.
- FULL SIGHTSEEING IN COPENHAGEN, MUNICH & ROME.
- ENGLISH SPEAKING FULL-TIME ESCORTS.
- HOSPITALITY DESK IN ALL CITIES.
- TRANSPORTATION VIA DELUXE MOTORCOACH.
- TIPS, TAXES, PORTERAGE INCLUDED.

ITINERARY FOR 16-DAY TOUR

News About Members

(Cont'd From Page 1)

Professor and Chairman of Audiology, Department of Otorhinolaryngology and Human Communication, University of Pennsylvania Medical School, Philadelphia, as of July 1, 1975.

LEO G. DOERFLER (University of Pittsburgh) received the Honors of the Association from the American Speech and Hearing Association on November 23, 1975, at the annual convention in Washington, D.C.

PHILLIP E. ROSENBERG will present the annual Moe Bergman Lecture at Hunter College in New York on December 10th, 1976.

EARL R. HARFORD, formerly of Northwestern University, is now Director of the Bill Wilkerson Hearing and Speech Center and Professor and Chairman of the Division of Hearing and Speech Sciences, Vanderbilt University Medical School.

E. JAMES KREUL has joined the California State University at Chico, California as a professor in the Speech Pathology and Audiology program. This program is scheduled to receive departmental status this fall (1976), with a faculty of six.

JAMES H. DELK is resigning January 1 as Director of Audiological Services for the Audiotone Division of Royal Industries to enter private practice in San Bernardino, California in the dispensing of hearing instruments. He will continue as consulting audiologist for Audiotone.

ARTHUR BOOTHROYD has just returned from a lecture tour in Italy, sponsored by the Amplifon Center for Research and Study. He covered 14 cities, from Turin to Palermo, discussing "The Role of Hearing in Education of the Deaf".

SAM LYBARGER was one of the invited speakers at the VII Danavox Symposium in Denmark, August 27-30. This is a scientific symposium sponsored by the Danavox Foundation and planned by the State Hearing Centers. Sam's papers were on "Comparison of Earmold Characteristics on the 2cc Coupler, the Zwislocki Coupler and Real Ears", and "Sound Leakage from Vented Earmolds". The proceedings of these annual symposia are published and available from the Danavox Foundation.

A new standards writing group has been formally established by the American National Standards Committee on Bioacoustics (S3) to begin working on a standard for acoustic impedance/admittance instruments and measurements. David J. Lilly, Ph.D., has been appointed Chairman of the new standards committee. The committee membership will be composed of persons involved in (1) basic questions and calibration; (2) instrument manufacture; and (3) clinical applications of acoustic impedance measurements. Several members of the A.A.S. will be on the committee.

SANFORD GERBER was promoted to full Professorship of Audiology at the University of California at Santa Barbara in July 1975. He was also elected vice-president of the Society for Ear, Nose and Throat Advances in Children (Sentac) at its November 1975 meeting in Mexico City.

Telex Announces Wireless CROS

Telex Communications, Inc., recently introduced the Tele-CROS Model 400, a wireless CROS hearing aid. This instrument entirely eliminates wiring in the CROS fitting. The microphone signal is transferred to the amplifier-speaker side by high-frequency electro-magnetic couplings, then transferred back to audible frequencies, and thereafter amplified normally.

The wireless feature allows this aid to be fitted as simply as a conventional eyeglass aid while enabling the user to have the advantages of CROS fittings. Fitting the Tele-CROS consists of merely attaching the aid with the proper adapters to the frame and bending the paddles for a comfortable fit behind the ears.

Calendar of Events

JANUARY

12-16:

Military Hearing Conservation Workshop, Aberdeen, Maryland.

26-30:

Postgraduate Course in neuro-otology, Department of Otolaryngology, Hospital General del Centro Medico Nacional and the Mexican Society of Otolaryngology, Mexico City.

30:

Conference on Piagetian Therapy, Children's Hospital, Los Angeles, California.

FEBRUARY

No date:

Conference on Early Intervention Programs for Hearing Impaired Children at University of New Mexico, sponsored by Indian Health Service (Dr. J.L. Stewart, Albuquerque).

19-20:

Second Annual Voice Institute, The Methodist Hospital, Houston, Texas.

28-29-March 1:

Mardi Gras Otolaryngology Symposium, Department of Otolaryngology and Maxillofacial Surgery, Tulane University School of Medicine, New Orleans.

MARCH

Feb. 29-March 5:

The Shambaugh Fifth International Workshop on Middle Ear Microsurgery, Chicago, Illinois.

6-13:

10th Colorado Medical Audiology Workshop, Vail, Colorado.

14-21:

American Decibel and Diopter Society, Annual meeting, San Diego, California.

19-22:

International Hearing Aid Seminar, Hotel Islandia, San Diego, California.

22-25:

Neurotology course, Department of Otolaryngology of the Abraham Lincoln School of Medicine and The University of Illinois Eye and Ear Infirmary. (Enrollment limited to 15.)

25-26:

Annual Meeting, American Otological Society, Palm Beach, Florida.

MARCH

25-27:

Third Course in Clinical Neuro-Otolaryngology, Eye and Ear Hospital of Pittsburgh University of Pittsburgh School of Medicine, Pittsburgh, Pennsylvania.

APRIL

5-9:

Acoustical Society of America, Washington, D.C.

12-14:

1976 IEEE International Conference on Acoustics, Signal and Signal Processing, Philadelphia, Pennsylvania.

21-24:

Canadian Speech and Hearing Association, Halifax, Nova Scotia.

25-28:

National Spring Meeting sponsored by the West Virginia Academy of Ophthalmology and Otolaryngology, White Sulphur Springs, West Virginia.

MAY

6-8:

American Academy of Private Practice in Speech Pathology and Audiology, Louisville, Kentucky.

12-16:

American Cleft Palate Association, San Francisco, California.

26-29:

International Conference on Cholesteatoma, University of Iowa, Iowa City, Iowa.

27-29:

ASHA Western Regional Conference, Portland, Oregon.

JUNE

13-15:

XIII World Rehabilitation Congress, Tel Aviv, Israel.

15-18:

International Symposium on Childhood Deafness, Central Michigan University, Mt. Pleasant, Michigan.

JULY

12-23:

61st annual course in Head and Neck Anatomy and Clinical Otolaryngology, Indiana University.

(Cont'd on Page 7)

Abstracts of Papers Presented to the A.A.S., Nov. 5

Relevance of Clinical Research to the Rehabilitation of Persons With Auditory Disorders. Norma T. Hopkinson, Ph.D., Pittsburgh, Eye and Ear Hospital.

Rehabilitation is used in the broadest sense of the word to include learning more about the auditory system in order to apply it to persons with auditory disorders. The danger lies in studying the system on an analytic, fragmented basis, and never integrating the two ears on the same head, on a neck, on a torso, etc., so that the system is viewed as a part of a functioning total being.

In clinical investigations of an ear for diagnostic purposes, I think an ear tries to tell about itself and what it contributes to hearing. We are limited in our interpretations only by our knowledge and ingenuity as to how to get the ears to reveal their mystery. Sometimes the finding is fortuitous. For example, when a patient who responded to a conventional pure tone test as if he had a low-frequency loss of sensitivity in one ear became a subject in a forced-choice experiment, he had no loss of sensitivity. The durations of signals and the time between them were highly specified and controlled. Accurate sensitivity levels could be obtained despite a serious central nervous system disease. On the other hand, if we had concerned ourselves only with the accuracy of his levels, we would have known very little about his very rapidly adapting responses. While it is important to have specific control ver signals to learn certain facts about an ear, it is also important to allow the ear some freedom to tell its mystery.

If we are going to worry about two ears and how they interrelate on a head, then we must look at them together as well as separately. Examples of methods for studying the interrelationships were given. Under conditions of amplification with a hearing aid on one ear, but two ears with which to relate to the environment, I am convinced (at the gut-feel level) that the hearing aid user experiences something more akin to alternation and interruption of forward and backward masking than to filtering of speech.

Finally, a few questions for rehabilitation purposes. What does binaural listening under earphones have to do with binaural listening in a controlled sound field, and what does either of these have to do with "bilateral" listening in the park or cafeteria? We add confusion to these questions if a hearing aid is used and if the variable of age is included. How does the person function in a communicating society and who is the judge? The ultimate measure of applied research is what it does for the human's right to a quality life, for

the person's right to be able to contribute to society. The ultimate test of the total person is the nature of his rehabilitation.

Electrocochleography. Nelson J.S. Kiang, Ph.D., Massachusetts Eye and Ear Infirmary.

Electrocochleography has given the clinician a practical device for measuring the responses of the auditory nerve with non-invasive techniques. The theoretical foundations for interpreting the results are being elucidated in basic studies.

New Directions in Sensory Aids Research for Speech Training. Robert A. Houde and Donald D. Johnson, National Technical Institute for the Deaf, Rochester, New York.

The "problem" of speech training for the prelingually deaf is that the quantity of formal individual training required to achieve functional speech is greater than that which can be provided within the resources allocated by society. If we eliminate the possibility of changing the resource allocation, we must look for approaches which will significantly improve the effectiveness of the speech training effort. Past attempts to develop more effective speech training "methods" have not resulted in success. Now new directions are developing in the field of instrumental speech aids which promise more direct assistance to this problem. The new directions arise from the realization that the principal role of instrumentation may be to provide the student with the ability to drill and practice relatively independently, freeing the teacher to concentrate on the unique instructional component of training, thus achieving the required quantity of individual speech training without an increase in teacher effort.

It is to this end that the exciting new advances in speech signal processing and display are being directed. Typical of the new systems which have the ability of providing independent drill are the computer based display of Bolt, Baranek and Newman (1), the Visual Speech Training Aid (VSTA) developed by the Center for Communications Research (CCR) (2), and, more recently, the Speech Spectrographic Display of

CCR, a modern version of the Visible Speech Translator of 30 years ago. These instruments were designed with the simplicity and ease of operation foremost, and now the task of structuring speech training to take advantage of their ability to provide independent drill and practice is being addressed.

Looking further to the future, the recent work on vibrotactile vocoders by Engelman and Rosov (3) and Electrotactile vocoders by Saunders (4) suggest the possibility of "wearable" speech reception aids which will allow speech training to take place in a more natural setting.

"Quantitative Analysis of the Romberg Test: 1. Technique and Initial Results." by F. Owen Black, M.D.

A Methodology for the objective characterization of the vestibulo-spinal control system capabilities in the human would add significant information to the clinician's evaluation of patients with vertigo and balance disturbances.

With the aid of the quartz crystal force platform and PDP/11 computer programs x-y plots of a patient's center of mass are relatively easy to obtain. Additional analysis such as position from gravity vertical versus time and rotation of the positional vector versus time can be performed with ease. This determination combined with position versus velocity plots (for damping characteristics) are useful in the diagnosis of musculo-skeletal versus labyrinthine versus oculomotor input and control abnormalities in the human. Data from normal and abnormal subjects were presented to demonstrate the markedly different patterns obtained from each group of subjects.

Playpersons of the Month

"ECSTASY ONCE A YEAR"

Your Past president Aram Glorig and new president "Dix" Ward on a recent moose-hunting trip in Canada.

Chuck Berlin

Appointed as

1976 Chairman

The 1976 annual meeting of the American Audiology Society will be held in Las Vegas in October, preceding the annual meeting of the American Academy of Ophthalmology and Otolaryngology. Dr. Charles Berlin, Kresge Research Center of the South, New Orleans, La., is the program chairman. Members wishing to suggest items for the program should contact him. This year will be the first presentation of the Carhart Memorial Lecture, and there will be an exciting and informative program.

ACKNOWLEDGEMENT

Member, Irwin Klar, American Electro-medics, helped in the distribution of this promotional issue.

Invitation to Join A.A.S.

The aims of the American Audiology Society are to increase knowledge of human hearing, promote conservation of hearing and foster habilitation and rehabilitation of persons with hearing impairment. The Society disseminates information through this quarterly newsbulletin and through a bi-monthly professional publication, *Journal of the American Audiology Society*, and through the holding of an annual meeting.

The requirements for membership are a demonstrated

professional interest in the field of human hearing and at least a baccalaureate degree from a certified college or university. Two active members must sign the application for membership, and annual dues of \$20.00 must accompany the application.

We invite all eligible persons to apply for membership. The Executive Committee of the Society passes on the application for membership. Merely fill out the form below and send it with your check.

Membership Application Form

Name _____ Date _____

Home Address _____ City _____

State _____ Zip _____ Phone _____

This membership application must be supported by signed statements from two active members verifying the qualifications of the applicant and payment of the membership fee [\$20.00] to cover dues for the current year. When complete, return to:

Ross J. Roeser, Ph.D.
Secretary-Treasurer
American Audiology Society
1966 Inwood Road
Dallas, Texas 75235

Minutes

Continued from Page 3

cedure will be adopted.

The meeting next year occur in conjunction with Association for Research Otolaryngology, which m before the annual meeting of American Academy of Ophthalmology and Otolaryngology. Chuck Berlin was appointed Program Chairman.

Mrs. Marion Downs appointed as the Editor-in-Chief of AUDIONEWS.

After considerable discussion the following motion was made reaffirming the position of Executive Committee on issue: "The commercial use of the Society's name in any form is strictly prohibited. Display the Society certificate is construed as commercial use." In addition, an Ethics Committee was formed to monitor any violations. Ralph Norton was made Chairman of committee.

Jerry Northern has indicated to the Executive Committee that with his present commitments he is unable to act as Associate Editor-In-Chief of the Journal. A successor identified and will be contacted to determine whether he will be willing to assume this responsibility.

It was decided that members of the Society can members of standing committees. Non-members can be paid consultants to standing committees.

An election was held for offices of Vice President Assistant Secretary. Geary Candless was appointed as Vice President and Norma T. Hinson was named as Assistant Secretary.

The Editor of the Journal needs close contact with members of the Executive Committee. Therefore, it was decided to appoint the editor of the Journal as an Ex Officio member of the Executive Committee.

The Secretary/Treasurer indicated that the present system of having two signatures on each check sometimes delays important action. It was decided that to avoid any delay this procedure the Secretary/Treasurer be bonded and only the Secretary/Treasurer signature be required on checks.

There being no further business the meeting was adjourned at 4:30 p.m.

Respectfully Submitted

Ross J. Roeser, Ph.D.
Secretary-Treasurer

What You Always Wanted to Know

About the Council for Accreditation In Occupational Hearing Conservation

Yes, Virginia, there is a Council for Accreditation in Occupational Hearing Conservation, (CAOHC) and it is alive and well in Denver and parts east. Chaired by William Call, Denver otolaryngologist, it has not been sitting on its hands like other agencies concerned with hearing conservation. A brand new important publication has just been issued: "Course Outline for Course Leading to Accreditation as an Occupational Hearing Conservationist." It is available through the Secretary-Treasurer, Mildred Sittner, R.N., 1619 Chestnut Avenue, Haddon Heights, NJ 08035.

Other activities of CAOHC include: 1) an article reflecting "A Symposium for Editors - The ABC's of Industrial Hearing Conservation" appearing in *HEALTH & SAFETY* - July-Aug. 75, featuring Paul Michael, Ph.D., of the CAOHC Board. The article is titled "Down to basics on hearing conservation". 2) An article by Thomas J. Doyle, M.D. of Consolidated Edison, NYC, on CAOHC which appears in *AUDIOLOGY & HEARING EDUCATION* in the Oct.-Nov. 75 issue. Doyle is a Board member. 3) A fine article covering "Hearing Loss; the key to successful therapy", featured in the Novem-

ber 75 issue of *CONSULTANT*. Harold R. Imbus, M.D., of CAOHC was the author. 4) An editorial by Aram Glorig, M.D., in the September 75 issue of *SOUND & VIBRATION*. 5) The certifying of 1750 Conservationists to date, and 385 Faculty.

The entire roster of the CAOHC Board Members is:

AAIN

Lillian M. Bozenhard, R.N., 57 Marbern Drive, Suffield, Connecticut, 06078, 203-668-2525.

Jerger to Give Carhart Lecture

Berlin outlines '76 AAS Program

Chuck Berlin, program chairman for the October 5th AAS meeting in Las Vegas has announced the theme of the program as "Basic or Applied Hearing Science." He also announces that Dr. James Jerger has agreed to give the first Audiology Society Raymond Carhart memorial lecture on the afternoon of October 5th. The morning session will be devoted to papers from the membership. Papers are requested in any areas of basic or applied hearing science and should be sent to Program Chairman, Dr. Charles I. Berlin, Kresge Hearing Research Laboratory of the South, 1100 Florida Avenue, Building 164, New Orleans, Louisiana 70119, in Acoustical Society format. The format for Acoustical Society abstracts can be found in any program of the society. A sample abstract is as follows:

Frederic A. Tyszka
University of Wisconsin,
Stevens Point, Wisconsin, 54481
David P. Goldstein
Purdue University
Lafayette, Indiana
(Received 14 February 1974;
revised 22 April 1974)

J.D. Harris'
New Book

Masking level differences (MLDs) were used as a means of studying the interaural phase and amplitude relationships for a 500-Hz bone-conduction signal from both the mastoid and the forehead vibrator positions. The results of the investigation indicated that with the vibrator on the forehead there is a trend for a 500-Hz bone-conduction signal to be interaurally in phase and interaurally equal in amplitude. With the vibrator on the mastoid there is a trend for the bone-conduction signal to be 180 degrees interaurally out of phase and interaurally equal in amplitude.

An abstract of no more than 200 words must accompany each paper submitted. It should mention the subjects studied and the methods used and it should set forth quantitatively new observations and conclusions. Brief numerical results and their accuracy may be included.

(1) Abstracts must be submitted double- or triple-spaced and one paragraph only.

(2) If at all possible, avoid the use of reference citations within the abstract. If citation is unavoidable, the full citation must appear within the body of the abstract and not as a footnote.

Abstracts are due by June 15.

Progress Report On European Study Tour

Plans for the European Study Tour in October 1976, are progressing well and reservations are coming in with the majority being from the New York area.

Recent efforts on the part of our land agent assure us charter 707 if we do reach chart size (178 participants) and a significant reduction in air fare.

Co-operation among Bill Kriger, our land agent, Stig Carstén of Danavox, Dick Scott of St. men, Henry Meltner of Wid and their respective associates Europe already indicates smooth, unusually well-coordinated tour that should prove to be most enjoyable and enriching.

Any inquiries relative to the tour should be directed to: Frank L. Brister, European Study Tour, American Audiology Society, P.O. Box 359, H.P.U., Brownwood, Texas 76801.

(See Itinerary on Page 8)

The Suspense Story of the Year

OSHA Drags Heels on Noise Standard

The administration seems hesitant to release the official OSHA noise standard that would set in motion the hearing protection programs 13 million workers sorely need. At issue has been the question of whether to adopt OSHA's 1974 proposed standard of 90dBA eight-hour time-weighted average—or to change to an 85 dBA standard now, in five years, or in ten years. These alternatives have been bouncing off the heads of administrators and committee members for some time and will probably continue to bounce around for yet a longer time.

Originally OSHA contracted with Bolt, Beranek and Newman for an economic impact report to determine what would be the cost of industry's compliance with a

90 dBA standard as against an 85 dBA standard. This BBN report estimated \$31 billion for compliance with an 85 dBA rule and \$13 billion for compliance with a 90 dBA rule.

A second impact report was requested from BBN to estimate the cost of industry compliance with an 85 dBA standard after 5 years of the 90 dBA standard. This report gives an \$8 billion estimate of the cost for 85 dBA, assuming that industry has already complied with the 90 dBA rule. This estimate is based on engineering compliance only; \$155 million is added for costs of monitoring the noise.

For audiometric testing the costs are estimated as \$12.00 per worker annually for monitoring 13 million workers (\$155 million

per year), and \$20.00 for complete audiometric testing of 4.3 million workers (\$86 million annually).

The Labor Department's solicitor's office and the OSHA staff have not to date accepted the second report nor approved it for release. Under further consideration is adoption of the 85 dBA limit after 10 years of 90 dBA. Once any report is released a 45-day comment period is scheduled. After that OSHA will issue its final ruling at some as yet undetermined time.

AAS former president Aram Glorig comments on this situation in a recent editorial in *Sound and Vibration*. It is pertinent to reprint this editorial in its entirety:

HURRY UP AND WAIT

Months have passed since the hearings on the proposed OSHA noise regulations were completed. In the meantime, little or nothing is being done to protect the hearing of our labor force. We all know that the democratic process is sometimes slow, but when the imperceptible motion of bureaucracy takes over, decisions come to a screeching halt. While our "so-called scientists" argue about non-existent data and committees persevere in creating unmanageable monsters whose shape and character are dictated by diverse opinions based on unsatisfactory and meaningless data, the spectre of compensation for hearing loss grows larger and

News About Members

Wayne J. Staab, Ph.D., Director of Education for Telex Communications, Inc., completed a two-month trip around the world in March during which he visited deaf education programs, lectured at universities and National Acoustic Laboratories, and provided for hearing aid specialist education in those countries. Discussion with individuals involved in deaf education programs took place in the countries of Hong Kong, New Zealand, the Philippines and Iran. Lectures were given at the University of Witwatersrand, Johannesburg, South Africa, the National Acoustics Laboratory in Sidney, Australia and at the National Audiology Center in Auckland, New Zealand. In addition, training sessions were conducted for hearing aid specialists in the countries already mentioned as well as in Japan, South Korea, Taiwan, Indonesia, Singapore and India. Discussions with hearing aid manufacturers in some of these countries also took place.

Robert H. Payne of Indianapolis, Indiana - who has been in the private practice of audiology - is the Director of the Audiology, Speech Pathology and Electrostagnography Department of St. Francis Hospital in Indianapolis. He is also Director of Audiology Services, Inc., which provides diagnostic audiology services and other audiologic research services for the medical practice of Otology Associates in Indianapolis. He has a staff of audiologists as associates, and also a speech pathologist on his staff.

Phil Bellefleur announces that the Pennsylvania School for the Deaf has received a grant from a private foundation to develop a Radio-Teletype News Center for deaf people. The project will be conducted as a study to determine the value of transmitting radio frequency carriers to the homes of deaf families. The carrier waves will be reconverted into teletype signals allowing the deaf to receive local, national and international news.

Daniel Beasley has been appointed the Acting Assistant Dean for Graduate Studies and Continuing Education in the College of Communication Arts and Sciences at M.S.U., effective 1-1-76. His normal appointment is Assistant Chairman of the Department of Audiology and Speech Sciences.

At the Orthopedic Hospital and Rehab Center's annual dinner and membership meeting on January 15, 1976, Winifred Shufelt received a recognition award for her work in the Partin Speech and Hearing Center. It was a wood and bronze plaque with the following inscription on it:

ORTHOPEDIC HOSPITAL AND
REHABILITATION CENTER
Mrs. Winifred B. Shufelt
In appreciation for outstanding
service as DIRECTOR and
AUDIOLOGIST of the
PARTIN SPEECH AND
HEARING CENTER

Darrel L. Teter, Ph.D., of Denver, Colorado, will conduct two-day workshops in Electrostagnography in Lansing, Michigan, on April 23rd-24th, in Atlanta, Georgia, during May, and in Minneapolis during June, 1976. The workshops will include complete practicums and will cover principles, techniques and interpretation of Electrostagnography in the testing of dizzy patients. For additional information, contact TRACOUSTICS, INC., P.O. Box 3610, Austin, Texas, 79764, Phone (512) 444-1961.

Irving Shapiro was guest lecturer at the University of California Santa Barbara Speech and Hearing Center Research Seminar, March 1, 1976, discussing "Hearing Aid Evaluations".

Bill Behrends, M.A., C.C.C., is no longer in the Air Force Audiology, but has taken a position as Director of Audiology, Department of Otolaryngology, Medical Center Clinic, Pensacola, Florida. He is establishing a Clinical Diagnostic Audiology Center in The Medical Center Clinic.

Albert P. Seltzer, M.D., Philadelphia, Pa., presented a paper entitled "Electronic Ear Warmer" before the American Academy of Ophthalmology and Otolaryngology in Dallas, Texas, September 23, 1975.

Arthur Boothroyd, Ph.D., is serving as Co-chairman for the program of the 1976 Convention of the Alexander Graham Bell Association, to be held in Boston, June 23 to 26. The theme of the program is "Keys to Independence", with a heavy emphasis on the role played by research and technology in providing those keys.

Jean Stewart, Director of the Hearing & Speech Center of Agvia O. Richardson, M.D., recently participated in a series of workshops on language delayed-learning disabled children sponsored by the Guam Hearing and Speech Center. A workshop was held for the Island's physicians entitled "The Learning Disabled-Hyperactive Child". Various staff members from the Hearing and Speech Center also appeared on the program. Additional workshops were presented to school health counselors, public health nurses, elementary and secondary counselors, to the entire faculty of the elementary school and to all the special education teachers. In addition, an organizational meeting was held for a local chapter of the Association for Children with Learning Disabilities.

Hirosi Shimizu was one of the invited speakers at the International Congress on Education of the Deaf in Tokyo, Japan,

August 25-29, 1975. His paper was on "Medical Assessment of Deafness". He will be on the faculty of the 1976 Frederick T. Hill Seminar in Otolaryngology held in Waterville, Maine, August 1-4, 1976.

B. Hill Britton, Los Angeles, presented four lectures at the Oregon Academy of Ophthalmology and Otolaryngology meeting January 30-31. The subjects were: Carcinoma of the Ear, Glomus Tumors, Sensorineural Hearing Loss, and Neurotologic Evaluation.

Warren Johnson was co-sponsor of a conference on Early Identification and Assessment of Communicative Disorders in Children, February 4-6, 1976.

Effective 12-15-75, Abraham Shulman, M.D. is Acting Head, Division of Otolaryngology, Downstate Medical Center, State University of New York.

Wayne Staab was presented with an award for outstanding achievement in industry research for the United States Senate Hearing Aid Industry Conference 1974-75. A plaque was presented to him at the 1975 NHAS/ HAIC Annual Convention in Chicago in October.

William Hardy received two distinguished awards in 1975: The Whetnall Memorial Medal of the Royal Society of Medicine in London, May 1; and the Honors Award of 1975 by the Alexander Graham Bell Association for the Deaf, November 20, 1975.

The Department of Audiology and Speech Pathology at the University of Tennessee has inaugurated a multidisciplinary Noise Research Laboratory. Initial projects have been designed to inquire into the mechanisms of noise-induced hearing impairment. Included in the disciplines represented by the Laboratory and inter-departmental collaborations are developmental physiology, electrophysiology, audiology, auditory physiology, histology, cytology, electron microscopy and hemopathology. David Lipscomb is in charge.

The Northwestern Pennsylvania Society of Audiology under the direction of Jonathan R. Brown, M.A., Audiologist, is sponsoring its first birthday with a meeting at the Holiday Inn in Clarion, Pa. The Northwestern

Pennsylvania Society of Audiology meets on a quarterly basis and the meeting is essentially for audiologists in the northwestern Pennsylvania area. It is not restricted to audiologists, however, and students are welcome. Interested persons should contact Jonathan R. Brown, M.A., Audiologist, at Ear, Nose, and Throat Associates, 122 Prospect Avenue, Franklin, Pa. 16323. Telephone: (814) 437-6848.

Dr. James MacDonald of the Nisonger Center of Ohio State University at Columbus will present his environmental language and parent training programs at the May Day Conference sponsored by the Department of Speech Pathology and Audiology of Southern Illinois University at Edwardsville; Gail Chermak, Head. The conference is open to the public and will be held on May 7, 1976.

Don Dirks, Center for Health Sciences, University of California, Los Angeles, spoke on "Current Developments in Audiological Diagnosis: New Uses of Impedance and Bone Conduction Thresholds" at the Association Speech and Hearing Association Central Region Mini Conference held at California State University, Fresno.

Jon Fitch announces that Dennis J. Arnst, Ph.D. has joined the staff of California State University, Fresno, Department of Communicative Disorders. He will teach undergraduate and graduate courses in Audiology.

Phil Rosenberg reports that the Audiology Department of Temple University Health Sciences Center is sponsoring a series entitled Audiology Colloquia-Temple (ACT). These colloquia are open to the audiologic and otolaryngologic community of the Delaware Valley.

Dr. Harold Bate, Professor of Audiology at Western Michigan University, will visit New Zealand for three months beginning May 1st as a guest of the National Audiology Centre and the New Zealand League for the Hard of Hearing. Dr. Bate will consult with the National Audiology Centre and various clinics around the country; conduct a refresher course for Tutors of the Hard of Hearing; and conduct a lecture tour on problems and needs of adults with hearing impairment. The Lecture tour will be associated with a national publicity campaign concerning hearing loss among adults, especially the aged.

Editorial...

(Continued From Page 1)

larger. Although the OSHA regulation has no direct bearing on compensation, its influence would be most meaningful in reducing future costs in human resources and dollars.

If the leaders of our fast growing bureaucratic dictatorship will not respond to the need for preserving human resources, what sort of "carrot" can we hold out to them? Is political position really more important than conserving human resources? If bureaucracy, labor and management are devoid of altruism, is it possible that the dollar cost of loss of hearing reflected in compensation awards can be effective in producing a decision? Such costs are nicely exemplified by awards recently made at two naval shipyards. A conservative estimate is five hundred million dollars for our ten naval shipyards if the remaining eight follow the pattern set by the two of them. If this is extrapolated to the entire population, the numbers become astronomical.

If the importance of conserving human resources and the enormity of the actual and potential cost will not convince our decision makers of the importance of the noise regulation, what will?

Aram Glorig, M.D.

Dr. Morton Corn to Speak at

'Summit' Meeting

A conference featuring top echelon people in the national industrial hearing conservation picture is scheduled for April 26-27 in Denver. The meeting is sponsored by the National Services Division of the Colorado Hearing and Speech Center of which H. Tom Buelter is Director. The featured speaker will be Dr. Morton Corn, Assistant Secretary of Labor for Occupational Safety and Health. He will speak on "New Directions in Hearing Conservation".

Other outstanding participants will be Frank Barnako, Chairman of the OSHA Review Committee, and Dr. Floyd Van Atta, formerly Senior Scientist with the Department of Labor. In addition, several international and national experts including AAS President W. Dixon Ward, will discuss hearing conservation concepts from a legal and practical viewpoint. Engineering concepts also will be discussed from the aspects of economic and technical feasibility.

Enrollment is limited to 120 people. The fee is \$150.00. For further information write to: Colorado Hearing and Speech Center, National Services Division, 1450 South Havana, Aurora, Colorado 80012.

27-29

The Triological Society, Palm Beach, Florida.

MAY

6-8
American Academy of Private Practice in Speech Pathology and Audiology, Louisville, Kentucky.

12-16
American Cleft Palate Association, San Francisco, California.

26-29

ARA to Hold High Country Meetings

The Academy of Rehabilitative Audiology will hold its summer meeting on June 28-30, 1976, at the High Country Inn in Winter Park, Colorado. The program will deal primarily with the rehabilitation of the geriatric hearing impaired individual. One session titled "Training Programs and Development of Community Resources in Geriatric Rehabilitative Audiology" will be presented by Joan Erickson, Jan Colton, Dean Garstecki and John O'Neill. Raymond Hull will present a session dealing with "Practical Aspects of Geriatric Rehabilitative Audiology". Another session dealing with "Rehabilitative Audiology with a Non-Institutionalized Geriatric Population" will be presented by Edward Hardick, Ethel Mussen and Ralph Rupp. A session titled "Audiologist or Hearing Clinician: Terminology and Professional Responsibility" will be

Sataloff and Aram Glorig, at the University of Maine at Orono (Bangor,) Maine.

12-23:

61st annual course in Head and Neck Anatomy and Clinical Otolaryngology, Indiana University.

OCTOBER

5
Annual Meeting of American Audiology Society, Las Vegas, Nevada.

6-10
1976 Annual Meeting of O&O, Las Vegas, Nevada.

9-24
16 Day European Study Tour, Denmark, Germany, Italy.

16-24
9 Day European Study Tour, Italy.

18-21
International Audiology Society, Florence, Italy.

NOVEMBER

16-19
Acoustical Society of America, San Diego, California.

20-23
American Speech and Hearing Association, Houston, Texas.

1977

FEBRUARY

20-24
Ear Surgery course, J. Brown Farrior, M.P., Tampa, Florida.

Boys Town Institute for Communications Disorders in Children

Many of our members have been curious about what is going on at the new Boys Town complex. To answer their questions, Noel Matkin has furnished us with a complete description of the Institute.

The Boys Town Institute for Communication Disorders in Children is presently under construction in Omaha, Nebraska. It is being developed with private funds by Father Flanagan's Boys' Home, in conjunction with and adjacent to the new Creighton University Medical Center and is scheduled for completion in 1977. The facility has been designed, with input from a panel of national consultants, to serve boys and girls ranging in age from infancy to 18 years who manifest complex communication disorders.

The major component of the Boys Town Institute (B.T.I.) is a five-floor, 100,000 square foot Clinical Diagnostic and Habilitation Center containing medical clinics; audiology, speech, language and psycho-educational evaluation facilities; human communication research laboratories, as well as an inpatient medical-surgical unit to accommodate children who require surgical correction of deformities that impair their communication skills. A unique feature is an inpatient diagnostic floor which allows parents to stay with their children during periods of evaluation.

The second major component of the B.T.I. complex is the 20,000 square foot Preschool Language and Learning Center which adjoins the clinical building. The Center consists of a model facility in which prescriptive teaching will be carried out. A cluster of four family living units in which children requiring extensive language training will reside under the supervision of trained houseparents is attached to the Preschool Center.

In general, all B.T.I. programs are designed for the communicatively handicapped child who has sufficient intellectual potential to develop into a productive adult citizen. The severely mentally retarded child, as a rule, will not be eligible for acceptance in B.T.I. programs since exemplary programs have been developed for such children throughout this country.

The human communication research laboratories of the Boys Town Institute will conduct extensive clinical and basic research projects. New habilitation methods, clinical technology, and research data will be disseminated by the Institute for use by practicing physicians and clinicians, hospitals, clinics and schools for the ultimate benefit of all communicatively handicapped children.

An advocacy program, utilizing a problem-oriented approach, will be organized to

monitor services for each child while at the Institute and when he returns to his home. Each child advocate will be designated from the team of specialists serving the youngster. The child's advocate will also assume the responsibility of serving as a community liaison for continued follow up. Throughout the evaluation, a comprehensive program of education, guidance, and counseling for parents will be planned.

Boys Town recognizes the quality care and treatment for communicatively handicapped child can be prohibitively expensive, even for families of moderate means. While third party claims will be submitted, where appropriate, parents will not be required to pay for the unreimbursed cost of care and treatment provided to their child. However, a statement of the monetary value of the services provided to the child will be prepared and submitted to the family for their consideration.

The Institute is governed by the twenty-one member Board of Directors of Father Flanagan's Boys' Home. In addition, there is a National Advisory Committee to the Boys Town Institute consisting of sixteen members headed by the Chief National Consultant, Dr. John E. Bordley, and Professor Emeritus of Laryngology and Otolaryngology at Johns Hopkins University School of Medicine.

At present, seven professional staff are involved in the interclinical programs and the development of the Institute. They are:

Patrick E. Brookhouser, M.D., Otorhinolaryngologist, Executive Director;

Noel D. Matkin, Ph.D., Audiologist, Director Preschool Language and Learning Center;

Don W. Worthington, Ph.D., Audiologist, Director, Audiology and Speech Pathology;

Edward L. LaCrosse, Ed.D., Special Educator, Coordinator Extramural Projects and Resource Development;

Eric Javel, Ph.D., Auditor, Physiologist, Director, Auditor Physiology;

Arlene M. Matkin, M.A., Speech Pathologist, Coordinator Family Services;

Marion McMillan, A.B., Information Specialist, Director, Library and Information Center.

When fully operational in 1977 the projected staff will be approximately 150 individuals who will represent all of the identified disciplines needed to provide comprehensive care and treatment as well as to initiate innovative research studies.

For further information write to: The Boys Town Institute for Communications Disorders in Children, 8401 West Dodge Road, Suite 133, Omaha, Nebraska 68114.

Keeping Up with Otologic Medical Group

It isn't easy, but we're following our many members in the Otologic Medical Group of L.A. and the EAR Research Institute in their multitudinous activities. Recently two papers were presented at the Western Section meeting, "Ossicular Transplants: Histologic Findings in Animals and Man", by Fred H. Linthicum, Jr., and "Facial Palsy from Temporal Bone Fracture: Management and Results", by Jack L. Pulec.

The entire group is going down to Palm Springs to give a one day seminar on otology to all of the generalists and pediatricians of that area to update them as to what is available in the areas of not only surgical correction of ear problems but auditory rehabilitation. Eddie Johnson will be a participant. The aim is to put on similar seminars throughout the area so that primary physicians will know just what is available in the areas of diagnostic techniques both for hearing and otologic problems and vertigo and what is the current treatment of choice for the various problems. Emphasis will be on what they can take care of: acute otitis media, wax in the ear canal, etc., and what should be referred on to the otolaryngologist.

Three courses are being offered by the Institute during the rest of 1976:

May 16-28: Temporal Bone Dissection Course;

Aug. 1-13: Temporal Bone Dissection Course;

Oct. 10-22: Temporal Bone Dissection Course.

These courses are limited to 20, and are already filled.

Editors Win Merit Awards

On February 19th, Majorie Skafte, editor of HEARING INSTRUMENTS, and Kathryn Frame, associate editor, were presented with a Certificate of Merit in the Jesse H. Neal Editorial Achievement Awards.

These awards are presented annually by the American Business Press, Inc., the association of specialized business publications. The award was presented to Ms. Skafte and Ms. Frame for their work in publishing the special April 1975 issue on "Progress in Hearing Health Care: The American Indian."

Assisting them in the preparation of this special issue was AAS member Dr. Jerry L. Northern, who coordinated the work in gathering the articles that were utilized in presenting the special report. Others who contributed to this special series were George DeBlanc, M.D., Raymond T. Wood III, M.D., Karen Bedwell, M.S., and Pat Blomstrom, M.A., Geary Lewis, Ph.D., Charles A. McCandless, Ph.D., Charles Lewis, M.A., Joseph Stewart, Ph.D., and Malcom D. Graham, M.D.

New Location Announced for Colby College Courses

The University of Maine at Orono (Bangor), Maine, announces that the 24th Annual Institute in Occupational Hearing Loss and the 13th Annual Industrial Hearing Conservation Institute, previously held at Colby College and directed by Doctors Joseph Sataloff and Aram Glorig, will be held on June 28 to July 2, 1976 at the University of Maine.

The facilities of the University of Maine provide improved accommodations and comfort for participants.

The Institute on Occupational Hearing Loss is designed for industrial physicians, safety engineers, hygienists, otolaryngologists, health management executives and administrative personnel. Designed to permit certification in audiometric proficiency, it awards 27 credits in PRA Category 1 of AMA for physicians. It covers the total field of conservation of hearing programs, medico-legal and compensation aspects, and OSHA developments. Lectures and laboratories are combined with practical field trips to couple theory and implementation. Tuition \$252.50, Room and Board \$25.00 per day.

The Industrial Hearing Conservation Institute is concerned with responsibilities of industrial

Incidental Information

According to the government's first annual report to Congress and the President on the state of the nation's health, the second most commonly reported chronic condition is hearing loss. The first is arthritis.

nurses and those actively interested in hearing testing performance and record keeping. Participants are eligible for certification by the Council for Accreditation in Occupational Hearing Conservation and for 2.6 CEU's by the Maine State Nurses Association. Tuition is \$235.00 and Room and Board is \$25.00 per day.

For descriptive brochure and application, write or phone: UMO Coordinator, 1721 Pine Street, Philadelphia, PA. 19103, (215) 735-0205.

ADVERTISEMENT

We are a European manufacturer of audiometers, impedance meters, auditory trainers, silent booths and ERA systems. Our products represent a highly competitive and comprehensive line of instruments applicable to the otological institutions, to the speech and hearing centers, as well as to the industrial market.

For our new sales company in the U.S., we are seeking a 30-35 year old experienced audiological technician, with excellent sales capabilities, to hire on full-time basis to direct our U.S. sales.

We offer the possibility of acquiring sales with the back-up of a name already well-known throughout the world, of a product range of advanced technology and prestige, and a highly interesting working position with both rewarding career and income possibilities, in a fast developing market.

The Interrogatory

Q. Do you find that positional ENG testing is valuable in localizing a lesion?

Wallace Rubin, M.D., New Orleans, La.: No.

F. Owen Black, M.D., Eye and Ear Hospital of Pittsburgh, University of Pittsburgh: The function of the vestibulo-ocular system is basically to position the eyes at the approximate point in the skull which would allow re-orientation of the moving head to its environment in response to rotation relative to the environment. A nystagmus will therefore result in both normal and abnormal conditions. For example, if the head is rotated too rapidly or through too great an amplitude for the eye to maintain fixation on an object in the environment, a nystagmus or periodic correction of the eyes relative to the head will result. The general answer to your question "is positional nystagmus always abnormal?" is therefore, obviously, no. If, however, certain recording conditions are honored (including positioning of the patient) then a positional nystagmus recorded under these circumstances, in my opinion, is always abnormal. The reason for this is that the purpose of the vestibular system in the absence of vision is to yield information regarding the position of the head relative to gravity vertical. A nystagmus recorded under these circumstances of visual deprivation and with avoidance of over-stimulation of the vestibular labyrinth, indicates that the vestibulo-ocular reflexes are receiving information which indicates that the head is undergoing rotation. This obviously is not a normal situation.

In summary, a positional and positioning nystagmus may or may not be abnormal depending upon the recording conditions and the parameters of assumption of the movement under which the position is assumed.

Hugh Barber, M.D., Department of Otolaryngology, Sunnybrook Medical Center, Toronto, Ontario: It's necessary to specify test conditions. Positional nystagmus of Hallpike's benign paroxysmal type, whether recorded with eyes open or closed (ENG), is due in about 95% of cases to inner ear lesion of the side towards which, when undermost, the nystagmus is directed. Linear (horizontal, oblique, vertical) nystagmus that is recorded with eyes open and in primary position, that continues to beat vertically as long as the head position is maintained, usually with little associated vertigo, is good evidence of CNS (infratentorial) localization except for positional alcohol nystagmus. This is true of both direction-fixed and direction-changing types.

When positional nystagmus is recorded with eyes closed and effective alerting, the situation is more complex. Quite a bit of nystagmus is normal under these circumstances (see Barber and Wright, Adv. Oto-Rhino-Laryng. 19:276, 1973, S. Karger, Basel). When the "amount" of nystag-

mus is clearly pathological, direction fixed nystagmus is mainly (not exclusively) due to a peripheral cause, direction changing mainly (not exclusively) CNS cause, direction changing in a single position probably confined to CNS localization.

Alfred C. Coates, M.D., Texas Medical Center, Houston, Texas: When recorded behind closed lids, "pure" positional nystagmus (elicited by moving the patient SLOWLY into the test positions) can often be a valuable indicator of pathology, but neither the nature of the positional nystagmus (i.e. whether direction changing or direction fixed) nor the direction of the positional nystagmus has any mobilizing significance. However, paroxysmal nystagmus which is elicited by the relatively violent "Dix-Hallpike maneuver" and which is not the same thing as positional nystagmus does have localizing value. If the paroxysmal nystagmus is fatiguable, transient, accompanied by dizziness, it is usually peripheral and the downward ear is usually the involved ear.

Rehab Course to be Given at ASHA Regional

AAS member John R. Harris will present at the Western Regional Conference of ASHA in Portland, May 28th, a short course on "practical approaches used in Conducting Adult Aural Rehabilitation Groups." Since this convention is designed to be tutorial, he will be discussing the materials, techniques, and principles used in conducting an adult aural rehabilitation program utilizing college students as co-therapists. Another title for the presentation could well be "Things and methods hard of hearing adults taught me that were beneficial to them in assisting their adjustment to the hearing loss and the improvement of their communication awareness". As the rehabilitative audiologist for the HEARING SOCIETY, he became very aware of the necessity for additional assistance after the hearing aid evaluation has been completed, or for people who are not ready for a hearing aid but are having communicative difficulties.

While the improvement in hearing aids has provided more exacting scientifically designed pieces of equipment, he believes our fields have failed to look at the impact of the everyday quality of life the hard-of-hearing person endures. Many of the severe problems we discover could have been successfully handled in a group if the person would have been referred five, ten, or fifteen years earlier when hearing loss was first detected. With earlier referrals, many of the negative habits and barriers to productive communication could be eliminated, saving the person literally years of frustrations and emotional stress.

Communication from Members

—Perception is Subjective—

Not too long ago I authored an article in a popular trade magazine entitled "Hearing Conservation—A Call for Action". This article was not based upon a tested hypothesis nor was it otherwise scientifically contrived. It was, instead, an introspection concerning a perceived problem. It was a subjective disclosure of some observed situations dealing with a debasing, debilitating malady. It was the written result of a consciousness sharpened by experience, learning and concern. It was an attempt to communicate.

Today, as I think about the twelve years that have passed since my baptism into the scientific community, I find that my manner has mellowed, that my need to assimilate and divulge "facts" has lessened. I am more interested, now, in the synergistic process that involves man working with man toward a mutual benefit. I am less in awe of the "scientific" accomplishments of man if there is not also a resulting humanistic accomplishment. I have become turned off by the "objectivity" perpetuated by the news media and the academic community.

I am keenly aware of the need for feedback if communication is to take place. But even without feedback, the necessity for authenticity is no less important.

I understand better now what is meant by a service oriented society, and the "artificial scarcity" created by a consumptive oriented society.

Taking care of those in need

Editorial

The title of this issue might well be: "Two Editors in Search of a Format". We are obviously experimenting with a variety of topics and departments in an effort to find a content and style that will fill a need and please our members. To do this we ask advice and suggestions of the membership. Would you like to see more professional news, more research reports? Or would you prefer that the paper remain informal, irreverent and chatty? Perhaps a combination of the two approaches?

Of one thing we are certain—we will not take any sides in any controversy. There have been suggestions that we respond in some way to a recent article in a H/A journal pitting Audiologists against Otolaryngologists. We will not enter this brouhaha. Our purpose is to demonstrate that all disciplines concerned with hearing have a common stake, and that cooperation, not criticism, will best benefit those whom we serve. We will gladly publish items showing how all can work together with advantage—and there are many such examples in this present issue. We believe that men and women of Good Will comprise this organization, and that our goal is worth-while.

Continue to send in your items and suggestions. Your response has been fantastic, and we are indebted to all of you for your support.

must involve an awareness, a perception. There must be a sense of community, a sense of involvement that goes beyond the scientific jargon of the "professional".

So, in writing this, I urge for recognition of man's potential in the cybernetic era, a more meaningful utilization of man's possessed power. I urge an acknowledgement of the real needs of man and the pursuit of a remedy to take care of these needs. I urge a retreat from a stereotyping, dehumanizing judgement of others to a searching, listening, evaluative approach. I urge a participation by all in the development of understanding, and a utilization of energy for the betterment of mankind rather than the bewilderment of mankind.

I urge the development of a dialogue between groups so as to reduce the polarization formed by the unknown. This dialogue must be concerned with man's individuality and his capacity for change, keeping in mind that human beings have different needs at different times and that their growth does not follow neat, tidy intellectual lines.

In the professional world we are encumbered so much with the facts of an issue, the "objective" view of life. This is sterility at its worst, and communication at its poorest.

Gerald R. Bearce, Capt. MSC
ENT Clinic, Okinawa

Many Audiologists are unaware of the audiological facilities available at the Cleveland State University Speech, Language and Hearing Clinic, and we hope to change this. The City of Cleveland has had for many years several agencies which provide audiological services to hearing impaired persons including the Cleveland Clinic, the Cleveland Hearing and Speech Center (Case Western Reserve University) and the VA Hospital. Presently, CSU is the youngest of the audiological facilities in the city.

The CSU Speech, Language and Hearing Clinic opened in September, 1969. It is staffed by the faculty of the Dept. of Speech and Hearing and all audiological services and student training are provided under direct supervision. There are presently four audiologists on the faculty. Beverly A. Goldstein, M.A., the current Coordinator of Audiology and Assistant Professor has strong interests in the areas of deafness, rehabilitation, and hearing aids. David A. Metz, Ph.D. is the current Chairman of the Department and an Associate Professor and has been with the program at CSU since 1967. His major areas of emphasis are Industrial Audiology and Noise. L. Clarke Cox, Ph.D. is an Assistant Professor and his major emphasis areas include experimental audiology and central auditory testing. Cynthia J. Levi, M.A. is serving as a half-time clinical audiologist at CSU and as staff audiologist at St. Luke's Hospital. Cindy's main area of emphasis is medical audiology. Undergraduate and Master's level students are able to receive a well-rounded academic and

clinical education in Audiology at CSU through strong faculty guidance. Both the Audiology and Speech Pathology programs are accredited by ETB.

Since the CSU Clinic has opened, great strides have been made to develop the program into an excellent student training experience. There are presently 20 externships sights affiliated with our program, 10 of which are in Audiology. Our clinic also provides extensive speech, language and hearing screenings (including impedance audiometry) which allow for experiences with school age children and with the children and adults attending classes through the Cuyahoga County Board of Mental Retardation. The clinic itself receives referrals from many sources and students have considerable contact in hearing aid selections with adults as well as with children from the three hearing impaired programs of Greater Cleveland. Aural (re)habilitation therapy is available in the clinic with school age children, CSU hearing impaired students, and other adults as well as at two of the hearing impaired programs in the city.

The equipment and facilities available for training CSU students is quite new and diversified. There are three sound suites with two full range diagnostic audiometers. The clinic also owns many impedance audiometers, portable screening audiometers, and a "master hearing aid." There is also appropriate equipment to teach students to check the calibration of air, bone, and speech circuits of the clinic audiometers and to perform electro-acoustic analyses on clients' hearing aids as well as monitor the stock of clinic hearing aids. All eight therapy rooms have two-way observation mirrors and several of the rooms are hooked into a closed circuit video tape system.

Faculty and student rapport is an important aspect of the program at CSU. In addition to the audiology faculty, there are three Ph.D. Speech Pathologists and three full-time and two part-time supervisors in the speech and language clinic. Just about all of us hold CCC. We hope that you might visit us if you are in the Cleveland area and that if ever appropriate, recommend our program to others.

—Beverly A. Goldstein, M.A.

NAME THIS FAMOUS AUDIOLOGIST.

(Answer on Page 7)

Gross Heads Advisory Board

Better Hearing Institute Surgeons

The Better Hearing Institute of Washington, D.C., has approved Dr. Charles Gross as its Advisory Board Chairman and Dr. Gale Gardner as Associate Chairman. Tony Zale, former middleweight boxing champion of the world, is also a new Advisory Board member. Better Hearing Institute (BHI) is a non-profit public service organization of the hearing aid industry. Its purposes are to inform and educate people about hearing loss and to encourage those who suspect a problem to seek help.

AAS member Charles Gross has interested himself in hearing-aid related activities in his home state of Tennessee. He has been on the Advisory Council for the Tennessee Board of Hearing Aid Dispensers, vice-president of Hearing Instruments Institute and Medical Advisory Committee member of the National Hearing Aid Society.

Among BHI's public service offerings are:

"You and Your Hearing", a slide-cassette presentation for the general public. It focuses on the magnitude of hearing loss,

the types of hearing handicaps, the causes, warning signs, prevention and available hearing help. 12½ min. Order from BHI, 1430 K St. N.W., Ste. 800, Washington, D.C. 20005. Cost: \$45.00.

"They Overcame Hearing Loss", booklet featuring the personal success stories of 12 famous hard-of-hearing Americans who refused to let hearing loss stand in their way.

"Sounds or Silence? We Chose Hearing Help" - a new booklet available March 1.

"You Should Hear What You're Missing", a TV series featuring Art Carney, Gov. George Wallace, actress Nanette Fabray, comedian Norm Crosby, and singer Johnnie Ray.

"Teenage Memories", a new public service TV spot emphasizing the value of hearing and hearing help for teenagers.

BHI's Board is composed of: Joseph Lucke, Pres.; John Kojis, Vice-Pres.; Bob Lee, secy.; and members Larry Alkire, Don Galloway and Tom Arnold. Joseph Rizzo is Executive Director of the Institute.

Course for Hearing Aid Dispensers Offered

A program in audioprosthology is being offered thru the University of Texas at El Paso, Center for Continuing Education and Department of Drama & Speech, Division of Speech, Hearing and Language Disorders. It is under the direction of H.N. Williams, Chairman, Department of Drama & Speech.

The program consists of 12 continuing education courses for which upper division credit hours in the area of Speech, Hearing and Language Disorders will be given upon regular enrollment in the University. Individual courses may be pursued at the convenience of the enrollee, and awarded by the University as individual credits; however, a certificate of competence in Audioprosthology will be awarded only upon the applicant's completing the total 12 courses,

including 100 clinic clock hours of supervised practice.

Each course requires 16 clock hours of lecture and/or laboratory time, except one which requires 100 hours of supervised practice. All participating faculty will meet one of the following criteria: 1) certificate of competency in field involved, 2) licensed physician, engineer, hearing aid dealer, or attorney, or 3) recognized expert or lecturer in field involved.

Other news from El Paso includes:

The ASHA student groups of New Mexico State University and University of Texas at El Paso sponsored a workshop on "Language Problems of the Pre-Academic Child" on February 20 and 21st, at the University of Texas at El Paso. Guest participants included Dr. Tina Bangs of Houston, Texas, Mr. and Mrs. Steven Farmer of Las Cruces, Dr. LoPiccolo of El Paso, and Mrs. Irma Luna and Miss Norma Talamantes of the Ysleta

(Continued on Page 6)

Vernon Appointed As Associate

Editor of JAAS

Due to his many other commitments Jerry Northern resigned as the Associate Editor of the Journal of the American Audiology Society. Jack Vernon, Director, Kresge Hearing Research Lab, University of Oregon Health Science Center, Portland, Oregon, has been appointed to replace Jerry.

Book Reviews

"Industrial Noise Control Manual" - contains fundamental information to aid the user in understanding, measuring and controlling noise. It is written for persons having little or no knowledge in solving noise control problems. NEW Publ. NIOSH-75-183. Available from: 5600 Fishers Lane, Rockville, Md. 20852.

"A Litany of Sounds," by J. Donald Harris, 1975, The Amphora Press, Box N, Groton, Conn. 06340. \$7.50 postpaid.

Rarely does one have the privilege of reviewing the purely literary output of a fellow professional. It is thus a pleasure to commend to your inner listening this delightful prose offering of one of the greats in the field. There have been, and are, giants in the field who have demonstrated their deep comradeship with classical literature and arts, and who have shown in their speaking and writing an abiding love of the English language. Such men were Barry Anson and Georg von Bekesy—such a man now is Dr. Victor Goodhill. To their ranks must be added J.D. Harris, long known as a pianist of stature, a classical scholar, an appreciative naturalist, and a philosopher of the sciences as well as of the arts. Like the others, he presents the solid credentials of a Renaissance man.

How appropriate that this little book should concern itself with the sounds that have impinged on J.D. Harris' tympanum during a lifetime of sensitive and discriminating listening! In a series of short essays, he shares remembrances from his early youth in rural New England, from his lifetime absorption with music, and from his perceptions of nature, people and problems of the deaf. One listens with him to the sonorous honks of the Canada goose, the shrieking African dialect of guinea hen, the whickering of farm horses, the softly breathed berceuse of a grandchild in his arms, the deep breathing of a full-breasted woman sleeping on his shoulder, the birdsong of bobolink, redwing, meadowlark and Kildeer, and a winter silence pregnant with spring (I quote directly from his descriptions, of course).

Humor relieves the nostalgia at just the right times, and indeed seems to underlie every episode or description. "I had a professor once who told me that one of his most satisfying moments was when in the afternoon once or twice a week he could play golf. He would settle his spikes firmly in the grass at the first tee, waggle his derriere a time or two, then lay into the ball with all his might. He said that that loud thwack of a well-hit ball exhilarated him above the depression left in him most of the week from dealing with deans and dunderheads, implying that into this latter category I neatly fitted."

In "Sounds I Would Hear" J.D. celebrates the sounds he would like to hear, undistorted. He conjures the hearing aid industry "not to underestimate what some people would pay for a true rendition of these things, without any

consideration of size, battery drain and cosmetic appeal".

Particularly touching to me are the realities he portrays of a bucolic earlier New England. These are things that I as a Westerner have only known from reading. He evokes remembered Christmases that recreate a warmth we all feel in our own remembered Christmases, far from the jaded seasons we presently endure. The charm of these passages draws up well to the style and content of Dylan Thomas.

In addition, for us in the field of hearing, there is an admonition neither to pity nor to scorn the deaf and hard-of-hearing: "The richness of character, the compassion which many hypacusics of your and my acquaintance possess—it is a hard question whether you would wish to trade their rounded and many-faceted and wholly admirable personalities for a history of normalcy in all physical aspects—the chances are that our hypacusic friends without their hours and it may be years of relative aloneness and real heartbreak, would have developed like you and me, creatures of passing acquaintances rather than of deep friendships, sib to every butterfly of fashion, prey to every huckster, and addicts of gin, Geritol and TV. It is worth noting that the Theatre of the Deaf is replete with those who can mime the human condition without words, having plumbed the depths of that condition without words but with the inchoate aches and longings to which we all are heir, but to which most of use are insensitive through the veneer of our facile and stereotyped verbalization."

I thank J.D. Harris for sharing his humanity and his literary talent with us. And I heartily recommend this book to any one of you who would like for one exquisite moment to remember the sounds of his youth and the days of his life.

—Marion Downs

"Transportation Noise Bibliography", for individuals investigating the impact of transportation noise. Published by the U.S. Dept. of Transportation. Available from R.V. Giangrande, Technology Sharing Program Office, Transportation Systems Center, Kendall Square, Cambridge, Mass. 02142.

"Your Baby's Hearing—A Booklet for Mothers." A simply written and illustrated booklet telling mothers what to look for in their baby's auditory responses. Stresses consulting the physician if these responses are not seen at various ages. Includes simple language stimulation instructions. Published by Audiology Section, Department of Otolaryngology, University of Colorado Medical Center, Denver, 80220. Free examination copy. \$100.00 per 1,000.

"Never Too Young" by Virginia

Stern, 1976, Lexington School for the Deaf, 30th Avenue and 75th Street, Queens, NY, 11370. \$4.95.

A baby, even with a profound hearing loss, is never too young to listen.

This is the theme of a new book, "Never Too Young", published by the Lexington School for the Deaf for families, teachers, doctors, audiologists and others who live and work with hearing-impaired infants and young children.

Parents of hearing-impaired children should be more aware of all types of sounds, in order to help their children to learn to listen and also to learn to speak. As in all families, parents must plan enjoyable and instructive activities which help children to develop.

Written by Virginia Stern of the Lexington School, the \$4.95, 110-page book features 48 vivid photos by Robert Kaplan which show five common home situations experienced by all families (bathing a baby, washing clothes, cooking in the kitchen, traveling in a car, going out for a snack). The purpose is to demonstrate how any family can use these daily situations to help a child develop listening and language skills.

"Never Too Young" is the first professionally oriented training book for parents of hearing-impaired children. All of the children and parents shown in the photos have been enrolled in the Lexington School Infant Center.

As Mrs. Stern states in the forward of the book:

"In every home there are activities that occur over and over again, each day of the week: eating, washing, dressing, shopping, traveling. Although it would seem to be relatively simple for parents of a hearing-impaired infant to encourage listening and to talk naturally in these everyday situations, may parents become tongue-tied at home. Perhaps because they know that the earliest years are the crucial years in their child's development, they want to help so much and are afraid they do not know quite what to do, what to say."

The Hearing Conservation programs provided or monitored by the University of Texas at El Paso Speech, Hearing and Language Center expanded to include the El Paso Electric Company. The center now services the El Paso Gas Line Co., Northwestern Gas Line, Phelps Dodge, and the Electric Co.

The University of Texas at El Paso Speech, Hearing and Language Center will hold a special training session in Sound Level Measurement and Hearing Conservation for 10 Algerian Safety Engineers, May 24-27, 1976.

Impedance Audiometry Is Still Where The Action Is

Impedance audiometry continues to be everyone's favorite topic, even after it has received several years of extensive coverage in the literature and in numerous course presentations. The reason seems to be that the versatility of the impedance bridge is constantly being extended in a variety of research and clinical studies.

To the original tympanometry and acoustic reflex tests have been added new and ingenious observations. A Physical Volume Test identifies a non-intact tympanic membrane through the recording of an unusually large volume measurement. It thus becomes a means to demonstrate a nonobservable perforation behind an exaggerated anterior overhand or beneath an adherent crust obstruction of ventilating tubes or within a blind retraction pocket.

New interpretations are being made of the acoustic reflex. A unique exception to the bilateral absence of acoustic reflexes will show unilateral presence, rather than bilateral absence. When the probe is in the conductive loss ear, contraction of the stapedial muscle will increase the impedance of the ossicular chain and decrease the compliance of the tympanic membrane. The unilateral presence of stapedial reflexes in ossicular discontinuity is pathognomonic of fractured stapedial crura.

As reported by Jerger, researchers at Northwestern University and Baylor College of Medicine combined efforts to evaluate acoustic reflex findings in 30 patients with VIIIth nerve disorders. Acoustic reflexes were absent at all test frequencies in 19 patients, present but elevated or with decay in four patients, and normally present in seven patients. Sheehy and Schlosser found similar acoustic reflex results in 56 cases of acoustic tumors. These researchers conclude that the acoustic reflex measurements are the single most powerful audiological test in the diagnosis of VIIIth nerve tumors.

The most intriguing fact, evidenced from these Baylor-Northwestern data, is that the acoustic reflex is absent 30% of the time in patients with NORMAL HEARING who have

VIIIth nerve lesions. likelihood of absent reflexes rises to 70% with a moderate hearing loss. The absence of acoustic reflex, in light of or near-normal hearing, must be considered a significant finding until the presence of an acoustic tumor is ruled out. Conclusions in these studies that acoustic reflex findings are more sensitive to the retraction pathology than Bekesy speech discrimination tone decay test results, shape of the performance function for phonetically balanced monosyllables.

As a result of such advances in interpretation, training courses that have been offered by the Impedance audiometers manufacturers have been filled up, after five saturating the country with courses.

The Gen. Rad Co., Grason Stadler, and the American Electromedics Corporation have been responsible for high schools in impedance audiometry.

Gen Rad has featured Feldman as its instructor. American Electromedics features Jerry Northern and Jerger. The 1976 schedules of these companies follow:

Current Abstracts

Watrous, B.S.; McConnell, F.; Sifton, A.B.; and Fleet, W.F., "Auditory responses of infants" JSHD 40:30, 357-366.

The authors have developed from a masters' thesis of the senior author a paradigm of auditory response maturation during the period of life from 3 to 12 months. A pilot study of sixty infants resulted in the specific study protocol with response behaviors categorized in hypothetical order: 1) reflexive behaviors (involuntary, immediate); 2) early attending behaviors (voluntary, subtle); 3) attending behaviors (change in facial expression, searching but not localizing); and 4) localizing (immediate or delayed, by eyes, head or body, or a horizontal or vertical plane.)

The experimental study utilized 40 infants from a rubella follow-up project who were regarded as normal after undergoing pediatric examinations and testing with the Denver Developmental Screening Test. Three infants were 3 to 5 months of age, eighteen were 6 to 8 months of age, and nineteen were 9 to 12 months of age. Twenty-seven of the forty babies were male.

Test signals consisting of noise-makers and an adult male voice were presented singly to each ear in sound field at levels of approximately 50-78dB. Responses were recorded (positive, questionable, or NR) by two observers in the appropriate response behavior category. Percentages of actual to possible responses were derived and compared between age groups for the several categories.

Findings suggested a developmental pattern of auditory response with initial reflexive responses largely disappearing before 3 months of age and giving way to changes in activity level as a response to sound. These in turn reduced at around six months in favor of listening and searching behaviors, both precursors to localizing which the authors found to emerge at eight months of age. Localization was first horizontal and by 10-12 months occurred on a vertical plane.

The study has nicely systematized the observation of behavior upon which most audiologists depend in judging the hearing sensitivity of infants. With our increased attention to follow-up of high risk newborns, this kind of information should prove valuable for early identification and management of hearing impaired infants.

A major weakness of the study was the dearth of babies in the 3-5 month group, which leads the reader to invoke some caution about the generalized results. The authors recognized this shortcoming; it is regrettable they did not wait to publish until a well-balanced data base was available.

One also questions the wisdom of choosing rubella babies for a normative study of this sort despite the authors' efforts to insure the subjects were "normal". Reports of bizarre behaviors of these babies are legion, and their selection detracts from the other-

wise careful, credible report. It may be that they are representative of normal babies; like a scarlet letter, however, their designation is hard to overcome.

The presumed improvement of sensation level with maturation has implications for a study of this sort. I wonder, for example, whether the response behaviors of the 9-12 month old babies might have been more similar to the younger babies if test signals at comparable sensation levels (rather than intensity levels) had been used. A parallel study experimenting with signals of decreasing intensity as the babies mature would be of interest.

While it isn't realistic to cite every contribution to the earlier thinking about infant testing, I am saddened to note again the oversight of one whose observations stimulated much of our current thought. Kevin Murphy's work in infant testing (1962), particularly with respect to the development of localization behaviors, should certainly be credited.

"Auditory response of infants" has offered a workable method and some tentative guidelines for clinicians who evaluate the auditory responsiveness of children. It is one more step in defining the "auditory competence" Eisenberg would have us address (1970). The data from more babies and normal babies are needed to establish norms with which the clinician can be comfortable.

Carol Ehrlich, Ph.D.

Sprinkle, P.M. and Veltri, R.W.: Recurrent Tonsillitis: A New Concept. The Laryngoscope, Volume LXXXVI, pp. 58-63, Jan., 1976.

This article is an update of original data which further confirms previous reports by the authors to the effect that adenotonsillectomy is a reasonable tool in our armamentarium for the conversion of abnormal oropharyngeal and nasopharyngeal microflora to a more nearly normal state. The data presented suggests to the authors that recurrent adenotonsillitis is a bacterial-viral illness, the viruses in these children being EpsteinBarr and adenovirus. The bacteria involved are those which are found in the abnormal oropharyngeal and nasopharyngeal microflora of children with recurrent adenotonsillitis, i.e. Streptococcus pyogenes, Staphylococcus aureus, Hemophilus influenzae, Pneumococcus species, and the aerobes and anaerobes. The recurrences of adenotonsillitis contribute to the role of EBV and adenovirus in the tonsils and adenoids and their activation secondarily from a primary infection with another pathogenic virus or bacterium from an exogenous source.

This excellent and timely paper, along with previous publications of the authors, brings real solace to those of us in clinical practice who must decide whether tonsils belong "in or out." We know very well from experience that removal of tonsils and adenoids that are subject to re-

current infection, associated with obstruction to the oral and nasal airway, with cervical adenopathy and, too, frequently, with recurrent serous otitis media and its complications, is a very beneficial procedure. This reviewer would also direct attention to the need for the almost routine, x-ray study of the maxillary sinuses in these patients with recurrent adenotonsillitis, particularly when associated with serous otitis media, as virtually all of these patients will show some degree of maxillary sinusitis varying from mucosal thickening to complete opacification. The usual ten day course of the appropriate antibiotic will not clear up the sinusitis, through the adenotonsillitis will resolve, only to flare up again in a matter of a week or two. Such recurrences prove exasperating to parents and pediatricians. Antibiotics must be prescribed in these instances in adult doses usually and for at least twenty-one days.

"THE WAY IT SHOULD ALWAYS BE"

JIM CURRAN of Qualitone and Bob Briskey of Beltone present a lecture on ecdysiasm.

Tactile Speech Displays

For The Deaf

A group, including personnel from Massachusetts Institute of Technology's Rehabilitation Engineering Laboratory and Research Laboratory of Electronics, the Harvard Graduate School of Education and Harvard Medical School (Children's Hospital Medical Center), are pursuing several lines of work aimed at placing tactile devices on deaf persons. Their goal is to design and develop tactile aids that can be worn routinely by deaf persons, including infants, and that will provide a sufficiently rich display to allow reception of intelligible speech. The group, headed by M.C. Schultz of

Nanette Fabray Honored by BHI

Actress Nanette Fabray, star of theater, musical comedy, television, and motion pictures, has received the 1976 Better Hearing Institute "Better Hearing Achievement Award" in appreciation of her "outstanding public

service and education efforts on behalf of the hearing impaired." Announcement of the award was made today by Dr. Charles Gross, ear surgeon and BHI Advisory Board chairman.

Redskin Halfback Larry Brown Encourages Hearing Impaired in New BHI TV Announcement

Larry Brown, Washington Redskin halfback and pro football's Most Valuable Player in 1972, offers hope and inspiration to millions of hearing-impaired Americans in a new television public service announcement just produced by the Better Hearing Institute.

Release of the announcement will be timed to coincide with Better Hearing Month, a public information campaign conducted-

each May by BHI and other hearing organizations. The spot was made possible by a grant from the Battery Products Division, Union Carbide Corporation.

Mr. Brown, who successfully overcame his own hearing handicap, appears in a 30-second announcement that dramatizes the scope of hearing loss and the importance of hearing and hearing help.

"It was Vince Lombardi, the great football coach, who first discovered my hearing impairment," Brown said. "Lombardi noticed that I moved well on plays from one side of the line but that I was slow in moving out from the other side. He asked if I had a hearing problem, I admitted that I did, and he convinced me to have it corrected. Now, because of a built-in hearing aid in my football helmet, I can hear all the calls from both sides.

"Good hearing is essential to being a good football player," Brown added. "It is also essential to enjoying life and to living it to the fullest."

Joseph Lucke

Receives Award

Joseph C. Lucke, 30-year veteran of the hearing field and president of the Better Hearing Institute, has been presented the BHI President's Award by the Institute's Board of Directors for his "outstanding service as president of the Better Hearing Institute, May 1, 1975 to April 30, 1976." The award was presented by Ralph Campagna, first BHI President, at the Institute's recent board meeting in Chicago.

Among other developments at the Chicago board meeting was the election of new BHI officers and board members. Officers include: President Joseph Lucke, former president of NHAS; Vice President John Kojis, president and general manager of Maico Hearing Instruments; Secretary Donald Galloway, Beltone hearing aid specialist; and Treasurer Larry Alkire, public affairs director for Beltone Electronics Corporation. Other board members: Thomas Arnold, founder of Arnold Hearing Aid Company; Ralph Campagna, president of the Hearing Aid Industry Conference and of RCI, Inc.; and Barclay Smith, market manager for the Battery Products Division, Union Carbide Corporation.

The board explored new directions and planned new programs for the next BHI fiscal year beginning May 1, 1976.

ANSWER: Earl Harford, in the cellar of the old Bill Wilkerson Center, 1954. The child is Hal Williams' son, now 4 years out of the Marines.

(See Picture on Page 5)

On Going Research

HEARING LOSS IN SEARCH OF A CAUSE

We have recently reviewed the "risk factors" associated with the first 16 infants with confirmed severe hearing losses who were detected by the Crib-o-gram nursery screening technique. (1) These are shown in the enclosed table. Cases 3, 5, 6, 8, 11, 12, 13 and 16 were from the well baby nursery, and the others from the ICU nursery. The medical records on these kids are quite complete and include multiple viral and CMV titers on anyone who was at risk by history or by clinical impression. There are some interesting, if not completely startling, facts here.

The table shows that in many instances we had more than one risk factor to cope with in finding a cause. In two we found nothing suspicious. Bilirubin levels ranged from 10 to 21 mg%, and two were below 12 mg%. This very strongly suggests that the risk level for hearing loss secondary to hyperbilirubenemia be reduced downward drastically from the 20 mg% criterion. Seven babies were given potentially ototoxic antibiotics, all of whom had normal kidney function. However, we have no reason to believe these drugs were a cause for hearing loss. We have followed a large group of such antibiotic-treated neonates and have not found any suspicious hearing losses. The fact that these children were placed on antibiotics (mainly for respiratory or prophylactic indications) may suggest that infection itself might have been involved in some of the hearing losses.

Some of these children had three years of medical records at the time of this review. Trips through these older children's records yielded a not too surprising number of clinic visit notes in which the "causes" for the hearing losses had become obscured and occasionally changed to a diagnosis at complete odds with the facts.

Frederica R. Jones, R.N.
(1) Simmons, F.B. and Russ, F.N., Automated Newborn Hearing Screening, The Crib-o-gram, "Archives of Otolaryngology," 100:1-7, July, 1974.

Jaime Benitez, Kenneth Bouchard, and Yong Choe (Division of Otoneurology, William Beaumont Hospital, Royal Oak, Michigan) have an ongoing study on the effects of partial lesions of the vestibular nerve upon the vestibular function of cats. This research is sponsored by a grant from N.I.H. So far, animals with lesions of about 50% of nerve fibers of the superior division of the vestibular nerve show a thermal vestibulometry "fatigue curve" similar to the one reported by Litton and McCabe in humans with acoustic neuroma. Jaime will participate in a temporal bone course in Paleopathology at the Department of Anthropology, the University of Tennessee in Knoxville, April 12-13.

The Ear Research Institute has had in operation for the past year a scanning electron microscope and has just acquired a transmission electron microscope. We feel that this will be a particularly productive laboratory in that, to our knowledge, we have the largest access to fresh human material in the country if not the world due to the vast amount of neuro-otologic surgery that is done here. Malcolm Graham is in charge of the laboratory and assisting him is one of our newer members, Dr. Antonio De La Cruz.

—Fred H. Linthicum, Jr.

**AMINOXYACETIC ACID
PROTECTS AGAINST
NOISE-INDUCED COCHLEAR
HAIR CELL LOSS**

Aminooxyacetic acid protects against noise-induced cochlear hair cell loss. R.P. Bobbin, M.S. Guth, and A.B. Mines, Kresge Hearing Research Laboratory of the South, Louisiana State University Medical Center, Department of Otorhinolaryngology, 1100 Florida Avenue, Building 164, New Orleans, Louisiana, 70119.

Aminooxyacetic acid (AOAA) has been shown to reversibly reduce the endocochlear potential (Bobbin, R.P. and Gendra, M.I. *Ann. Otol. Rhinol. Laryngol.*, 84:192 (1975)]. In this study

guinea pigs were pretreated with AOAA (20 mg/kg, s.c.) or saline 50 minutes prior to exposure to a 30-minute, 4 kHz, 126dB SPL tone. The animals were sacrificed 21 days after exposure and hair cell counts conducted by means of the

surface preparation. Animals pretreated with AOAA prior to intense tone exposure demonstrated a significant reduction in the number of destroyed hair cells. We speculate that the endocochlear potential plays a role in

noise-induced hair cell d
tion.

ology, neuro-surgery, neuromuscular disease, neuropathology, sensory physiology, otopathology, otolaryngology, audiology, and speech pathology. This award, made to an institution, provides a superior candidate with an opportunity for five years of special study and/or experience tailored to his individual needs. The award bridges the gap between the postdoctoral period of clinical study and a secure academic appointment.

Candidates must be citizens or noncitizen nationals of the United States and they must be nominated for the proposed program by a domestic non-Federal public or private nonprofit institution. Candidates should have completed, at the time of receiving the award, at least three, but usually not more than six years of post-doctoral training and/or experience, exclusive of required military service. The most competitive candidate is

one who has either just completed or is in the final year of residency training or is just completing three years of doctoral training and experience.

Dates for the receipt of applications are February 1, 1987, and October 1. For further information, contact: Raymond W. Myers, Ph.D., Assistant Director for Manpower Programs, National Institute of Mental Health, Division of Manpower Activities, National Institute of Neurological and Communicative Disorders and Stroke, Bethesda, MD 20892. July 1976

AAS Program Outlined

The annual meeting of the American Audiology Society will be held in The Las Vegas Convention Center, which is a part of The Las Vegas Hilton. The annual AAS meeting will precede the annual meeting of The American Academy of Ophthalmology and Otolaryngology, and will run consecutively with the Association for Research in Otolaryngology.

Those attending the meeting should make their own reservations for lodging. A list of nearby hotels include:

Ceasars Palace	735-6797
Desert Inn	735-1122
Frontier Hotel	734-0110
Hacienda Hotel	739-8911
Las Vegas Hilton	732-5111
MGM Grand Hotel	739-4111
Riviera Hotel	734-5110
Sands Hotel	735-9111
Stardust Hotel	732-6111
Tropicana Hotel	739-2222

Dr. Chuck Berlin has done an outstanding job this year and our program will be the most comprehensive ever. Dr. James Jerger will begin the formal program and will present the first Carhart Memorial Lecture. Contributed papers will follow Dr. Jerger's lecture and a short business meeting will close the day. A summary of the meeting can be found on page 12. Admission is \$5.00 for members, \$8.00 for non-members.

Rasmussen Receives Award

This year's award of the Belton Institute for Hearing Research was presented to Dr. Grant Rasmussen of the University of Minnesota. Each year the Institute gives a one thousand dollar award and citation to an outstanding researcher in the field of Hearing. Dr. Rasmussen was honored at a dinner in Bethesda, Maryland on May 11, 1976 attended by many friends and associates.

The citation for Dr. Rasmussen read: "A respected contributor to our knowledge of auditory neuroanatomy throughout his entire professional life, Grant Rasmussen has truly impressed his mark on this field of scientific research. His doctoral thesis, which established him as an independent, accurate observer and suggested the concept of centrifugal control systems in the brain, was but the beginning of a long and fruitful career. Rasmussen's Bundle will be remembered long after many superficially more exciting discoveries have been forgotten. The recent explosion of interest in the sensory coding at the cochlear nucleus and other brainstem nuclei is due in no small part to Dr. Rasmussen's careful anatomical observations, including unpublished results which he has always unselfishly shared. Many subsequent physiological researchers have received valuable personal assistance from him, and have themselves published noteworthy studies. Numbers of his students have maintained active interest in the auditory system and are now making their own contributions."

The Board of Trustees of the Institute awarding the honor are: S.F. Posen, Chairman, Joseph E. Hind, Jr., Ph.D.; John R. Lindsay, M.D. and S. Richard Silverman, Ph.D.

[Continued on Page 2]

The President's Message

W. DIXON WARD
President, American Audiology Society

It was a bit disconcerting to find myself the second president of our Society for two reasons. In the first place, I have always disliked those who seek power, and am even suspicious of those on whom it is forced. Secondly, I am neither an otolaryngologist, a hearing aid dealer, nor an "audiologist" in the restricted American sense (someone who has a degree in audiology). However, like the rest of our members, I do have a keen interest in the hearing process. Furthermore, the post of president, happily, does not involve much real power (may it always remain thus), and perhaps the fact that my interest in selling hearing aids is nil will permit me to view with some degree of objectivity the present conflict among those in control of certain national organizations who, in the name of "public interest", seek government-guaranteed monopolies.

The process that eventuates in state-mandated monopolies usually begins innocently enough, as a professional organization tries to protect the consumer against fraud. Through the use of certification procedures, the organization attempts to guarantee the competence of all its members who have a service or product to sell, be it a medical diagnosis, an audiometric examination, or the fitting of a hearing aid. If everything went as it should, such a system would be all that would be needed to protect the consumer adequately. Were certification procedures sufficient to weed out the incompetent and the dishonest, the public would soon learn that accreditation by a particular organization was a sufficient condition (though not a necessary one) to guarantee a basic standard of service. The citizen, then, would be prudent to determine that his physician was suitably accredited by a well-known medical organization, his otolaryngologist by one of more specialized range, and so on. On the other hand, if he did not so determine credentials, or deliberately chose to seek service from someone who was not accredited, such choices should be his to make. The legitimate role of government could then be invoked: to ensure that laws existed that would permit the prosecution of those who claimed accreditation by a certain group but did not in fact have it. Under these conditions, most persons who could meet the accreditation requirements would find it advantageous to join the organization; although it would not be illegal for a witch doctor to claim to be a healer, for example, but finding customers, without certification, would be a problem.

If an accrediting organization got too big (and hence, it appears, inevitably too ponderous and too expensive), then a group of dissidents would be free to resign, establish a new organization, and begin their own accreditation. It might take a while for the reputation of the new group to become established, but in the long run the action could be expected to pay off for its members. It would obviously be to the advantage of the consumer of the group's services, since competition would eliminate price-fixing.

So much for what could happen in a free society. Unfortunately, open competition seems to be an activity that many people like to see others engage in, but not themselves. Instead, they seek "security" in the form of monopoly—if not only for themselves, at least for their in-group. Such individuals find willing accomplices in politicians, who are always glad to gain control of anything. The state willingly sets in concrete the requirements for certification, either raising by an order of magnitude the fee for the examination in order to pay for the new bureaucracy that is now "needed", or else designating the instigating organization as the sole examiner; in any event, they establish precisely what certification entitles one to do and, by implication, what the uncertified cannot do. Of course, this is justified in the public eye in terms of "protecting the citizen against charlatans"; however, a close examination shows that all he is being protected against by the paternalistic state is his own stupidity, a protection that libertarians like myself would rather do without.

My suggestion, then, is that if, as I believe to be the case, the members of our Society are more freedom-oriented than the individuals who remain in the organizations from which we fled or are fleeing, we should devote as much time as we can spare to the abolition of government controls in all aspects of our business of measuring, protecting, and improving hearing, rather than remaining aloof completely from the conflict between rival certifying agencies. It would be a serious mistake to merely chuckle as we

[Continued on Page 2]

Corti's Organ Salutes Wm. Hardy

On the occasion of his receiving the Honors Award of the Volta Bureau on November 20, 1975, it is appropriate to review the long and illustrious career of this great contributor to the field of Audiology.

No stuffy pedant, he. For several years, 1932-35, he participated in the then burgeoning radio theatricals, both as a writer and producer. The young among you probably never heard of "Omar, the Wizard of Persia" who was Bill Hardy's brain child. This and other radio dramas were his babies—long before he became the godfather to many thousands of real babies who owe their improved communications to him. A publication in 1936, "Radio and the American Language" is a memento of this early interest.

Dr. Hardy was born in Cleveland, Ohio, then migrated at a tender age to South Chicago which then (1911) was habitable. Shortly thereafter (1914) he moved his family to Westchester County, New York where he managed his way through high school in Yonkers. Emerging from this at fifteen, he went to Packard Commercial

Editorial

Questions are often asked us about the Society and its makeup. We thought we would take this opportunity to answer those questions most frequently asked.

The purpose of the Society is specifically stated in the Statutes, and is iterated on each membership certificate: "...to increase knowledge of human hearing, promote conservation of hearing, and foster habilitation and rehabilitation of the hearing impaired." The Society was purposely formed as a non-competitive group, and is not in competition with any existing organization. The Society will NOT become involved in political issues; will NOT become involved in union type activities, such as licensure; and will NOT in any way provide professional certification for its members. Membership specifically implies an interest in the purposes and goals stated above and that is all. It is recognized that minimal membership requirements are low. This is so that individuals who have demonstrated an interest in human hearing who cannot participate in existing organizations may join.

As of June 1st the Society had 780 members. Of this number 46 hold bachelors degrees, 354 hold masters degrees, and 380 hold a doctorate degree. Finally, and most important, there is no truth to the rumor that Corti's Organ is hard of hearing and irreverent; it can hear and does listen. We thank everyone who is making it a success. RJR/ MPD

Corti's Organ Salutes

[Continued From Page 1]

School in New York, learned typing and shorthand, and for a short time worked for the Tidewater Oil Company.

Thereafter came Brown University and a healthy career in tennis, the Glee Club (undertaken as the No. 1 brass-baritone), and a goodly amount of bridge. His undergraduate majors were Political Science, History and English Literature. Came then a year as a graduate instructor in English and Linguistics. Even then, universities were expensive and, there being no genuine employment in 1932, he began to fiddle around with radio writing and production.

This began at WINS with a variety of literary undertakings, and was continued the following year with an assignment as the unseen writer of "Your Unseen Friend," which was a daily presentation of one of the "power personalities" then popular in those days. There followed a jaunt to Chicago with a variety of other assignments including, "Omar the Wizard of Persia," which was a real money maker. There were various further things undertaken at WMAQ including some participation in the "Nickelodian Theatre" and a wide variety of single shots for Irene Rich, who was one of the current stars of the day. So it went until the academic job market opened once more and he was able to get back to more sensible employment in one of the best teacher's colleges in the East, New York State College for Teachers, Albany.

Dr. Hardy received his Ph.D. from Cornell University with majors in Rhetoric, Speech Science and Linguistics. His doctoral dissertation was on "Modern Semantic Theories," presaging the swell of interest in General Semantics of the 1950's. In 1944 he became one of those historic few who developed Audiologic services in the armed forces. At the U.S. Naval Hospital in Philadelphia he directed the aural rehabilitation and speech service which was among the pioneers in establishing modern-day concepts of audiologic services in the armed forces.

Other pioneering efforts took place in the field of early detection, diagnosis and management of the deaf and hard-of-hearing child. At the John Hopkins Medical Institution he became the director of the Hearing and Speech Center in 1947, and served there until his retirement in 1975. He continues actively as a consultant to the Graduate Program at the John Hopkins University.

It is difficult to describe the varied activities and contributions of this incredibly able man, but perhaps the flavor of his energies can be described in just a few of his recorded activities:

1948: Consultant in Audiology and Speech, Maryland Departments of Health and Education.

1955: Chairman, Study Section on the Hearing Impaired Child, World Health Organization. Instructor, American Academy of Ophthalmology and Otolaryngology; Editor, in Audiology, "Cerebral Palsy Review"; Associate Editor, "Journal of Speech and Hearing Disorders".

1968-70: President Elect-Alexander Graham Bell Association for the Deaf.

1968-73: Council Member, National Advisory Council, National Institute of Neurologic Diseases and Stroke.

1970: Consultant, Committee on International Exchange of Persons (Senior Fulbright-Hays Program).

Honors: Dunn Scholar, Brown University, 1930; Gaston Prize, Brown University, 1931; Sphinx Club (honorary scholastic) Brown University, 1931; Phi Kappa Phi (honorary scholastic, graduate) Cornell University, 1943; Sigma Xi; (the first to be awarded) Annual Achievement Award by the Maryland Public Health Association, Inc. (1970); Member, Wisdom Hall of Fame, 1970. Honor Award, (1974) American Speech and Hearing Association; Honor Award, (1975) Alexander Graham Bell Association for the Deaf.

As a finale, Dr. Hardy's current activities and scientific endeavors include:

Development of Hearing in the first year of life (with J.B.L. Hardy and H. Shimizu: N.I.N.D.B. "Collaborative Project on Cerebral Palsy and Related Neurological Disorders").

Screening young children for hearing, language and speech development (with M.P. Hardy, J.E. Bordley, and J.B.L. Hardy: "Collaborative Project").

Study of auditory input factors relative to deviation in language-learning in preschool-age children (with M.P. Hardy, H.L. Haskins, et. al. N.I.N.D.B. Research Grant B-3887).

Comparison among electrodermal, electroencephalographic, myographic, and vascular responses to acoustic stimuli in animal and man (with H. Shimizu).

Collaborative Project in the development of children and the effects of certain diseases on hearing in man (with J.E. Bordley and Y. Kapur, Christian Medical College, Vellore, India: N.I.N.D.B. Research Grant).

"Communication Problems and Psychologic Functioning in Children with Congenital Rubella" with J. Hardy, D.W. Welcher, J.E. Bordley.

Corti's Organ is happy to salute this leader in the audiology profession.

Cholesteatoma Conference Sparks Interests

The recent First International Conference on Cholesteatoma, sponsored by the University of Iowa, was attended by leading otologists and basic scientists from all over the world. The conference was the brainchild of Jacob Sade of Tel Aviv, Israel, currently a visiting professor of otolaryngology at the University of Iowa. Guest of Honor was George Shambaugh, Jr.

The first two days of the conference were given over to the basic scientists, starting off with a panel which attempted the difficult task of defining adequately what cholesteatoma is, a term which itself is really a misnomer. The etiology of cholesteatoma, including the migration, congenital and metaplastic theories were then discussed by a panel consisting of Maxwell Abramson, Eugene Derlaki, and Jakob Sade. Although no final conclusions were reached, apparently each theory can be substantiated in given cases.

Geographic, socio-economic, and racial factors in cholesteatoma were presented by a number of speakers. Coman and McCaffery reported an incidence of as high as 50% chronic otitis media in Australia aborigines, yet 0.08% incidence of cholesteatoma. On the other hand Tschopp reported 12% incidence of C.O.M. in Eskimos with somewhat less incidence of cholesteatoma in 1961. However, by 1970 incidence of C.O.M. had dropped to 2%.

Smyth reports an extremely high, apparently 50%, incidence of bilateral cholesteatoma in northern Ireland.

The last two days of the conference were devoted to the various surgical methods of treating cholesteatoma. The various discussions were sharply divided advocating intact canal wall procedures vs. Bondi's open techniques. Cody reported an incidence of 35% recurrent cholesteatoma with an additional 20% "pre-cholesteatoma" in wall-up technique. Only 6% recurrence was found in open and 19% open techniques followed by obliteration.

On the other hand Jansen reported only 2.3% recurrent cholesteatoma in his large series of wall-up procedures. Palva reports recurrent cholesteatoma in his series of open procedures followed by obliteration.

Smyth, Wright, Austen and Sade all agreed that intact canal wall procedures for cholesteatoma should all be re-explored 1-2 years because of the significant risk of recurrent and/or residual disease.

It was apparent at the conclusion of the conference that from both the basic science and the clinical side more questions have been asked than were answered and the need for a 2nd International Cholesteatoma Conference was re-treated.

—Susan Clift, M.D.

NAHSA Meet Cancelled

For the first time, the National Association for Hearing and Speech Action cancelled its customary annual conference, which was to be held in Columbus in June. NAHSA faces a reorganization in its executive staff due to the resignation of Tom Coleman, executive director for the past 10 years. President J. Hank Smith announced that the cancellation of the meeting was necessary in view of the financial burden of searching for a new executive director. Associate director Ben Drew has been named acting director.

In his 10 years with NAHSA Tom Coleman completely re-

versed the downhill slump of the former American Hearing Society. After renaming the society, he accomplished a number of outstanding innovations which carried the association into broad fields of public education and improved business management.

In addition to Coleman, E. Porter also resigned from the organization. Mr. Porter was director of education and training for the past 12 years. A long time consultant to the Vocational Rehabilitation Administration, Mr. Porter will become associated with the Professional Rehabilitation Workers with the Adult Deaf.

The President's Message

(Continued From Page 1)

watch one group struggle with another over who should be granted dictatorial powers in the form of monopoly by the state. In the libertarian view, the only legitimate function of the state is to protect us from our fellows, not to protect us from ourselves nor to initiate programs of "liberal" do-goodery, and if we are not more militant about resisting government encroachment on our lives, the freedom we still have will become ever lessened.

As William Allen White said many years ago, "Liberty is the one thing you cannot have unless you grant it to others." If we press for controls of what others may not do, we will assuredly find ourselves hoist on our own petard. And it would serve us right. So let's not let it happen: let us instead work for abolition of all government controls of personal service activities except laws against fraud and misrepresentation. Just 200 years ago this month, our forebears began a struggle to rid our country of the shackles of an oppressive government. They almost succeeded; maybe we can.

Oticon Cited for International Achievement

The Oticon Foundation was recently awarded the "International Technical Trophy" for industrial excellence at elaborate ceremonies in Paris, France. The International Trophy is awarded by the International Institute for Promotion and Prestige which is associated with the United Nations Educational, Scientific and Cultural Organization (UNESCO). With this honor Oticon joins numerous other outstanding contributors of scientific achievement, outstanding techniques, new technology and other important contributions. Previous award recipients whose achievements have been recognized with the International Trophy include the US National Aeronautics Space Administration (N.A.S.A.), on the occasion of the moon landing, the Academy of Sciences of the U.S.S.R. on their 250th anniversary, Zambia

Industrial and Mining Corporation (ZIMCO) and the Oceanographic Museum of Monaco.

In an impressive ceremony held at UNESCO Building in Paris, and attended by the Danish Ambassador to France, a Minister of the French government, Mr. Bent J. Simonsen, Director of the world-wide Oticon Foundation and Companies accepted the "International Trophy" from Madame Gisele Rutman, Executive Vice President of the I.I.P.P. Also in attendance at the awards ceremony was a group of American press personnel on tour with Oticon Corporation (USA).

Mr. Simonsen, in his acceptance speech, cited the growth of the Oticon Foundation through the years. "When in 1904 the founder of our organization - today spread over the entire world - brought home with him a hearing aid from London for his hearing impaired wife, he had no means of knowing that he had laid the cornerstone of an expansive enterprise. From this one hearing aid grew an organization which is today honoured by the "International Institute for Promotion and Prestige".

"Social progress since the second world war in a great number of countries in the western hemisphere has meant the public bodies have realized the importance of giving financial support to the rehabilitation of the hearing impaired population, because a hearing impairment is a handicap which is often considered a more serious handicap than the loss of vision. The Danish hearing aid industry blossomed during the years after 1950, and William Demant, son of the founder of our organization, foresaw that, in this situation, it was very necessary to consolidate the future work to be done for the hearing impaired all over the world. With this objective in mind, the Oticon Foundation was brought to life in 1956. As owner of all the shares in Oticon enterprises, the Foundation has secured the financial possibilities to carry out the human and social work laid down in the statutes of the Foundation."

"Approximately 5% of the world population has a need for hearing support which may be met by fitting a hearing aid - and this need is far from being met. In Denmark, a country considered to have a very high social standard, we have covered approximately 60% of the demand. For reason of comparison I can add that this percentage is 23 in the Federal Republic of Germany, 22 in Belgium, 10 here in France, and 9 in Italy. Only in recent years has a greater understanding of the special problems of the hearing impaired begun to emerge in a number of countries. Thus there seems to be more work to do in the future, also for the Oticon Foundation."

Mr. Bent J. Simonsen, Member of the board of the Oticon Foundation and C.E.O. of the Oticon group of companies world wide accepting the award "Le Trophee de la Technique" for Oticon's outstanding work in research and development for the benefit of the world's hearing impaired population. French Minister Leo Hamon is on Mr. Simonsen's right; Madame Gisele Rutman of the Institut International de Promotion et de Prestige [the international institution giving the award] stands in front of the French tri-color flag.

BBN Conducts Impact Study

In addition to their OSHA study of the inflationary impacts of various noise regulations, (see April Corti's Organ), Bolt, Beranek and Newman has been commissioned by NIOSH to do another far-reaching study. BBN will assess occupational exposure to impact and impulsive noise in American industry.

The first step in such a study will be to identify the sources of impulse noise in a variety of industrial settings. BBN is requesting that anyone knowing such sources should contact BBN in Cambridge, Massachusetts.

Former A.A.S. president Aram Glorig made this comment on the study, "It is high time that impulsive noise and its effect on human hearing was studied thoroughly. Most of our information so far is from gunfire, and that isn't very definitive. One of the problems is that impulse noise varies from time to time. Even gunfire measures out at different levels at different times."

"Another problem," Glorig stated, "is that any study of impulsive noise initially requires ground rules describing what impulse noise is. In the past, no one has bothered to describe what it is. A description in terms of duration and peak level is the crucial point in such a study. Until such parameters are agreed upon, no study can be productive."

NOTICE TO MEMBERS

Please send us your news items or contributions for the October edition of Corti's Organ. Deadline is September 1.

News About Members and Others

Hiroshi Shimizu, M.D. has been appointed the Director of the Hearing and Speech Clinic in the Department of Otolaryngology at John Hopkins School of Medicine.

At the Los Angeles Otologic Medical Group a luncheon was recently held for two secretaries, Agnes Ward and Ruth Greulich, to celebrate the completion of the processing of the 250th pair of temporal bones. The host at the luncheon was Dr. George Kelleman, Director Emeritus of the Eccles Temporal Bone Laboratory. All of these bones have complete clinical records. It is hoped that evaluation of them in the Larrabee Laboratory will shed more light on the causes of sensorineural loss. A current project is to determine how many patients might be suitable candidates for the cochlear implant, i.e., how many neurons remaining in spite of the loss of the organ of Corti. So far it appears that about two thirds of the patients have at least sixty percent or more of the neurons remaining in the osseous spiral lamina and a normal ganglion cell count.

Dr. Malcolm Graham, Director of The Electron Microscope Laboratory at the Ear Research Institute hopes to achieve his Ph.D. at the University of California at Los Angeles in Electron Microscopy in the not too distant future.

A project to be started at the Ear Research Institute by Dr. John House is the use of biofeedback to try and control tinnitus.

Daryle Waldron reports that the Audiology-Speech Pathology Service at The Medical University of South Carolina, Charleston, has moved into its new quarters in the recently completed clinical services building. The service is staffed by three audiologists and one speech pathologist, all of whom hold the ASHA certification.

Gil Herer, Children's Hearing and Speech Center, Children's Hospital, National Medical Center, Washington, has been elected President-Elect for 1977-78 of the Maryland Speech and Hearing Association.

Harris Pomerantz, University

of South Florida College of Medicine, Tampa, is conducting a field trial of Blair Simmons' (Stanford University) Crib-O-Gram at Tampa General Hospital, and with neonatologist John Curran and otolaryngologist James Endicott of University of South Florida, has developed a High Risk Registry for congenital deafness, in cooperation with Communications Awareness Project, a local voluntary agency directed by Barbara Stefany.

"On the first of January, 1976, the Department of Otolaryngology at Queen's University, Kingston, Canada, opened its human Communication Research Unit on the campus of the Hotel Dieu Hospital. The Head of the Department is Malcomb Williams, F.R.C.S., (C); and the Unit Director, who is also an associate professor in the Department of Otolaryngology, is John O. Darbyshire, M.A., Ph.D.

The main function of the new unit is to carry out an epidemiological and demographic study of speech and hearing needs in south eastern Ontario, with particular regard to children and to senior citizens. Research is also being undertaken, under the direction of Z. Jacobson, M.A., Ph.D., into visible speech for children. Other research projects which are about to start will investigate social factors in families with young hearing impaired children, and the feasibility of establishing vocabulary norms for young Canadian children, both anglophone and francophone.

In view of the relatively unique nature of the new unit, contact with interested professionals both in the United States and elsewhere would always be welcome. Communications should, in the first instance, be sent to Dr. Darbyshire, at the Jeanne Mance Residence, Hotel Dieu Hospital, Canada.

Dr. Robert Frisina, Director of NTID, was recently in Hawaii to do a survey of the programs for the hearing impaired in Hawaii. The Departments of Education, Health, Social Services and Housing, Senior Citizen Programs, Parks and Recreation, etc. were all surveyed to come up with sug-

gestions and recommendations to improve and make more available services to the community.

An Information and Referral Center for the hearing impaired has been opened in Honolulu. This hopefully will act as a clearing house and get services to the public. The Center is operated by the Hawaii Council for the Hearing Impaired, a private non-profit agency. Evalyn Inn, audiologist, is president of the organization.

David W. Holmes, formerly Director of Audiology and Aural Habilitation at the New York State School for the Deaf at Rome recently accepted a position at the University of North Carolina, Institute of Speech and Hearing Sciences, Chapel Hill, North Carolina 27514. Plans are underway for the development of an Educational Audiology Program which will certify graduates by ASHA and by the Council on Education of the Deaf. Additional plans include a Deaf Infant/Parent Program at Chapel Hill.

Robert C. Cody, Director of the Speech and Hearing Clinic, West Virginia University Medical Center, spoke on "Impedance Audiometry in School Hearing Screening Programs" at the annual state convention of the West Virginia Speech and Hearing Association in Charleston. To emphasize his enthusiasm for combining impedance measurements with pure tone audiometry ("tympano-audiometric screening"), through the course of his presentation he stripped away his jacket, tie, and shirt to reveal a now infamous T-shirt inscribed with the phrase, "Stick it in your ear!" (courtesy of the American Electromedics Corporation). Having given a historical resume of school hearing screening from the days of the descending numbers phonograph test to the present innovation of including impedance measurements, he clearly indicated that "...We've come a long way, baby!"

Frank Kleffner, has accepted the position of Director of the Institute of Logopedics. He will begin his new job September 1.

THE INTERROGATORY

Question: In what circumstances do you feel it is advisable to recommend binaural hearing aid use?

Kenneth W. Berger, Ph.D.
Kent State University, Kent, Ohio

There is abundant evidence that binaural hearing is superior to monaural hearing in normal hearing individuals. Unfortunately, the evidence on binaural aided hearing, pro or con, is not so clear in cases of combinations of impaired ears. Presumed advantages of binaural over monaural amplification are: better sensitivity to sound, better speech discrimination in noise, and better localization of sound. Since the expected improvement in sensitivity under binaural amplification is minimal and not usually an important factor, and since improved speech discrimination has been elusive of proof, one judgement for recommending binaural hearing aids I make is on the basis of localization of sound. In some cases binaural aids improve localization, while in other cases localization ability is reduced.

We are beginning to attempt to quantify those hearing losses which are expected to permit localization under binaural amplification. Binaural hearing aids are recommended if the thresholds of the two ears differ by no more than 15 dB at any of the speech frequencies and are roughly parallel, if the dynamic range of each ear is about the same, and if at the same sensation level speech discrimination scores under phones differ by no more than 8%. Conductive losses with a larger difference in threshold contour or degree may benefit from binaural fitting.

Whether the person can readily afford two aids or can ill afford a second aid should not be considered a factor in determining binaural needs. Nevertheless, from a practical standpoint in the latter case the problem must be dealt with.

Mrs. Doreen Pollack, CCC-Sp A
Director, Speech and Hearing Services
Porter Memorial Hospital
Denver, Colorado

Although it is possible for man to function monaurally, the normal auditory system involves the reception of acoustic information from two ears within both hemispheres of the brain, both contralaterally and homolaterally. The advantages of binaural hearing have been well documented, and include overall ease of listening in group situations, improved speech discrimination especially in the presence of background noise, increased distance hearing, and the ability to localize the source of sound without a directional forced-head position.

If one of the goals of rehabilitation for the hearing impaired is to gain an optimal auditory function, it seems logical to try to duplicate the advantages of dichotic representation possessed by the normal hearing. For older people, one naturally has to weigh the advantages against

cost, ease of handling and other individual needs.

For young children, I believe true binaural fitting should be the fitting of choice unless it can be proved WITHOUT A DOUBT that there is a total loss in one ear, or other medical contra-indications. We have been fitting two separate aids for twenty years and have repeatedly demonstrated better speech and improved discrimination scores using standard tests WITHOUT LIP READING. For example:

	Pure Tone Average 500-2K	Aided SRT	Aided Discrimination HL Using WIPI
Right Ear	102 dB	35 dB	48% at 65 dB
Left Ear	105 dB	32 dB	48% at 65 dB
Binaural		30 dB	76% at 65 dB

Nevertheless, two major areas of controversy seem ever with us: (1) Does binaural fitting of asymmetric ears cause distortion? (We have no data to substantiate this.) (2) Should one ear be used at a time because of the danger of noise induced loss? We have followed cases for periods of up to 21 years who show no progressive loss but improved speech and listening skills, and we have seen cases of progressive loss, usually in one ear only.

E. Robert Libby, President
Associated Auditory Instruments
Upper Darby, Pa.

When the decision has been made that a hearing impaired individual with a bilateral hearing loss is a candidate for a hearing aid, we should automatically think of maximum compensation in the form of binaural amplification. In most other disabilities we tend to compensate as fully as possible. It is evident that not every candidate may need, afford, benefit or adjust to binaural amplification. It is also evident that an active school teacher has greater auditory needs than a 90-year-old geriatric, however, the evidence strongly supports starting with the binaural premise. The basic consideration should be can the client obtain greater benefit from the monaural or binaural situation. The benefits might be quite subtle and may be noted only in certain limited situations. Clinically the binaural advantage may be found in some clients and not in others; certainly without any real predictability. Shall we recommend binaural only for those where we found a clinical binaural advantage? Are we depriving many clients because of the inadequacies or our testing procedures? The final decision must rest with the subjective reactions of the individual.

The complexity and uniqueness of each client's auditory experience is such that the prediction of successful binaural use must be evaluated on an individual basis. My own experience strongly suggests that a hearing impaired individual with a bilateral loss deserves consideration for binaural candidacy, to be recommended on a trial basis with intensive after care counseling and orientation. The clinical evaluation is more a one time procedure while the binaural

The question arises—which ear would you choose? Residual hearing which is not used is of no advantage.

Residual hearing should be tested regularly, and the use of hearing aids monitored by an audiologist. The benefits of binaural hearing are measurable only after a period of intensive and well directed stimulation. I recommend the July, 1975 issue of Hearing INstruments which was devoted to binaural hearing and fitting.

adaptive mechanism is a process which can take many months before the binaural advantage is perceived.

With our rather remarkable technological advances in hearing aid design, greater knowledge of ear mold acoustics, utilization of reflex threshold measurements and central auditory processing procedures, there is more appreciation in the professional community for binaural hearing advantages. The future indeed shows promise for binaural amplification.

Darrel L. Teter, Ph.D.
Private Practice
Littleton, Colorado

1) When the aids are to be worn at ear level. It is not advisable to fit binaural aids when they are going to be body instruments, worn with three to four inches of separation between their microphones. When the aids are worn at ear level, the individual then, can benefit from the aids, and true binaural hearing and localization is obtained.

2) I would fit binaural hearing aids when the pure tone measurements for each ear are within 20 dB of each other, through the speech frequencies. This keeps one from fitting ears with great discrepancies, which will lead to a loss of the true binaural hearing experience.

3) I would fit binaurally with ear level instruments when the discrimination scores in each ear are reasonable symmetrical. I believe that they should be within 20% of each other, and preferably closer.

Joel M. Mynders
Philadelphia, Pa.

The art of fitting and selecting amplification has advanced steadily over the past forty years. With the advent of ear level type instruments, the fitting possibilities were increased to include binaural fittings. This type of fitting has been an area of controversy between hearing aid specialists and audiologists. The hearing aid specialists professional opinion of binaural fittings is based upon two factors. The first is the logic of using the two existing auditory pathways available for the best results from

amplification. The second is the positive attitude reported by clients who have been fitted with binaural hearing instruments. The content of these reactions is greater listening comfort in wearing a hearing aid when in the binaural configuration versus the monaural configuration. The reasons for this comfort are that when wearing two aids, the volume controls with two aids worn are set at a lower level, thus increasing the signal to noise ratio in many listening situations. Also the clients report that they are able to locate the source of sounds more effectively. It is also hypothesized by this fitter that the noise cancellation phenomenon of the Cortex functions more efficiently when the acoustic signals are binaurally amplified.

In our firm we fit somewhere between eleven to fifteen percent of our clients binaurally. The reasons for these figures are: 1) the criteria we utilize for binaural candidacy, 2) the imperfect methods that exist for demonstrating quantifiable binaural benefit, 3) the existing professional attitudes toward binaural fittings and finally 4) financial considerations of the client. However, the future of binaural fittings should be an upward incidence curve. The very same factors that have caused our low incidence of binaural fittings could change universally in the following manner. The criteria for binaural candidacy will expand to include many more clients. The audiologic methodology, using new discrimination tests will enable fitters to demonstrate binaural benefit with greater reliability. The attitudes of the professionals involved will endorse binaural fittings possibilities. Finally the dispensers will present a changed system of costs that will reflect an unbundled cost for services for binaural candidates. More specifically, this means that the fitters' services with a binaural fitting are not doubled, therefore the costs will reflect this and thus many more clients will accept the binaural recommendations from their fitter.

The controversy over binaural fittings should subside since it can profoundly affect the client's ultimate success with amplification as one type of treatment of hearing loss. The call for research on this type of fitting procedure should focus specifically in the area of effective tests for aided binaural function. The future of increased selective binaural usage by fitters will benefit many of the hearing impaired.

Binaural hearing aids should be viewed as the ideal or preferred method of amplification and each individual should be evaluated with this possible recommendation in mind. By the same token, however, some cases should not be viewed as potential candidates and the audiologist should base the choice for binaural vs. monaural recom-

mendation on demonstrated preference of one or the other arrangement.

Binaural aids appear particularly advisable in cases of bilaterally symmetrical losses with similar speech discrimination abilities and loudness tolerance levels for both ears. When ear level aids can be utilized in a binaural situation, this should be viewed as favorable over the use of two body aids. In assessing the potential benefit one can derive from binaural aids, I look to find similar aided responses for warbled pure tones, SRT, and whenever possible, discrimination scores at a 50dB HTL presentation level for both ears independently prior to introducing the binaural arrangement. If it is not possible to produce similar aided results for both ears after adequate evaluation, I then question the actual benefit that one would gain from the use of binaural over the use of monaural fittings.

With very young hearing impaired children possessing essentially no language skills, the initial use of amplification should be viewed as an evaluation period. I, therefore, hesitate to proceed with the recommendation of binaural aids in the very beginning and disagree with the practice of routinely fitting binaural for the initial experience with amplification. Initial audiologic information for these babies cannot provide insight into discrimination abilities, unless sufficient language is present to use in obtaining indications of both ears' abilities to discriminate speech. For this reason, I generally opt for a period of several months of adjustment to the aid, alternating its use between ears on a weekly basis. Thus, information regarding both ears can be obtained through observations by the parents, teacher, and audiologist regarding the child's responses coupled with the aided audiograms for both ears—to be used in making recommendations regarding binaural aids. If these observations indicate the child is receiving equal benefit from the aid in both ears independently, the introduction of binaural amplification can then be made with more assurance. Routine re-evaluation of the recommendation should proceed as the child develops, with in mind that initial hearing aid usage is an on-going trial period in very young children.

Michael C. Pollack, Ph.D.

Throat Medical Group, Inc.
Pomona, Ca.

While much of the research with binaural hearing aids has failed to demonstrate significant clinically discernable advantages when compared to monaural amplification, users frequently report these advantages. The main advantage seems to be in an improved figure-ground relationship. It has been my experience that many users find it easier to separate primary

[Continued on Page 5]

The Interrogatory

[Continued from Page 4]

speech signals from background noise with binaural rather than monaural amplification. Koenig refers to this as the "squelch effect."

I have not as yet discovered a foolproof method of determining whether an individual should use one or two aids. Since successful binaural use seems to be a very individual phenomenon, I believe that decisions for binaural recommendations must be based on the specific needs of the patient. What are the demands placed on his hearing? Is the person frequently confronted with situations that demand functional binaural hearing, such as business conferences, academic or social settings? If so, then binaural amplification should be considered, at least on a trial basis. I believe that binaural fittings are especially important for children in terms of the facilitation of educational and psychological growth. I rarely recommend two aids for geriatric patients. I find it difficult to justify the additional expense against the relatively slight gain in auditory functioning if the hearing demands are not significant. Naturally, this is not an inflexible policy, but is dependent upon the individual's realistic needs.

I ordinarily fit the binaural aids one at a time, giving the person a chance to adequately adjust to one, then two instruments. It has been my experience that binaural fittings are successful more often with this procedure than with immediate fitting of both instruments. In this way the patient can experientially evaluate the possible advantages of two aids; this, after all, is the most critical test.

Ear Surgery In 3-D

J. Brown Farrior is sponsoring a course on Mastoidectomy, Tympanoplasty and Stapedectomy in Tampa, Florida on February 20-24, 1977. The goal of this course is to show as much surgical pathology and surgical technique as can possibly be covered in three days. It will begin with lesions of the external auditory canal and proceed with tympanoplasties, mastoidectomies, tympanomastoidectomy revisions and causes of failure and then consider special techniques, as the removal of glomus tumors. The concluding lectures will be on stapedectomy techniques and causes of a failure.

Visiting firemen will act as discussants and panelists to present divergent opinions as to the indications and variations of the technique employed.

The course stresses the necessity for total knowledge of the temporal bone anatomy, pathology and surgical technique. The course will be illustrated by scientific exhibits which will open on Sunday. Three dimensional photography will be utilized to portray in depth the variable surgical anatomy and surgical pathology of the temporal bone.

The occurrence of acute bacterial otitis media in young infants under three months of age has been documented in the neonatal intensive care unit and the outpatient population. Autopsy studies on perinatal deaths have also demonstrated that purulent otitis media is a common finding. (4-5)

The ability to accurately diagnose acute bacterial otitis media with the hand-held pneumatic otoscope in the neonatal period has important clinical implications. Undiagnosed bacterial otitis media can become a focus for the development of more serious infections, such as sepsis or meningitis. (1-2,7) The symptomatology associated with bacterial otitis media in infants under six weeks of age also resembles these other infections. Symptoms associated with unrecognized bacterial otitis media can lead to a septic workup with the institution of antibiotic therapy, usually involving both ampicillin and an aminoglycoside. These antibiotics are usually discontinued at 48-72 hours if the cultures are reported as negative. This can result in inadequate treatment of the bacterial otitis media and cause a chronic partially treated otitis to develop.

It is important to determine the causative organism by tympanocentesis because the bacteriology of otitis media in this age group differs from older children. In contrast to older children with otitis media in whom ear aspirates yield predominantly streptococcus pneumoniae, hemophilus influenzae, and streptococcus pyogenes Group A (7-9), infants less than six weeks of age have been reported to have a high incidence of gram negative enteric infections and staphylococcal infections. (1-2) Despite these considerations, otoscopy is often overlooked in the intensive care nursery setting. The barriers to an adequate examination include: (1) narrow external auditory canals of a premature infant which are often occluded with vernicious debris; (2) a reluctance to disturb a sick infant often in an isolette who is intubated; receiving assisted ventilation; (3) the normal appearance of the tympanic membrane in a premature differs from that seen in an older child.

A cooperative study has been undertaken by members of the University of Colorado Medical Center's departments of Pediatrics and Otolaryngology to determine the prevalence of bacterial and nonbacterial otitis media in the neonatal intensive care nursery. The clinical presentation and bacteriology of otitis media in the neonatal nursery was also compared with that of otitis media in infants of the same age living at home. As part of this study, we have tried to determine the accuracy of bedside hand-held otoscopy. A member of the Pediatric Department with a special interest and experience in otoscopy examined 100 ears using a Propper hand-held oto-

scope with pneumatic attachment. The same ears were then evaluated in a double-blind system by an otolaryngology resident using a Zeiss binocular operating microscope.

Findings were identical in over 90% of the cases.

The results to date support the evidence that bacterial otitis media occurs commonly in the neonatal intensive care nursery. An association was noted between prolonged nasotracheal intubation and the presence of bacterial otitis media. The clinical presentation of bacterial otitis media in both the nursery and non-nursery infants under three months of age resembles the clinical presentation of other serious infections. There were several patients with otitis who also had either sepsis or meningitis.

Distinctively different flora were found to be responsible for suppurative otitis media in infants under three months old who were in the intensive care nursery and those at home. Outpatients with acute otitis media were found to have predominantly *Diplococcus pneumoniae*, *Haemophilus influenzae*, and staphylococcus species, while inpatients had staphylococcus and enteric gram negative organisms.

These preliminary data indicate that otoscopy should be done routinely on any neonate or infant with a clinical presentation compatible with sepsis. When otitis is diagnosed in an infant less than three months of age, a septic workup should be performed, which should include a tympanocentesis in addition to blood cultures, a spinal tap, and suprapubic urine. We feel that hand-held otoscopy can be a powerful diagnostic tool in the hands of a pediatric resident with adequate training in its use.

Memorial to Carhart Planned

A grant of \$1000 to Northwestern University for auditory research in memory of Ray Carhart has been made by the Beltone Institute for Hearing Research. Mr. L.M. Posen, president of BIHR, announced the grant, which has been accepted by Dean Roy Wood of the School of Speech at Northwestern.

Dr. David Rutherford, Chairman of Communicative Disorders will meet with the Trustees on June 7 for presentation of the grant. A plaque honoring Ray Carhart's contribution to BIHR will also be presented at that time. Dr. Lois Elliot, new Head of the Program in Audiology and Education of the Hearing Impaired, will also be present.

For many years Ray Carhart worked with the BIHR and it is in honor of his work the Institute the award is made.

The Center for Speech, Hearing, and Learning Disabilities at Hackensack Hospital, Hackensack, New Jersey, is conducting a two-year study on the ototoxic effect of tobramycin in the treatment of cystic fibrosis patients with pneumonia or other lower respiratory tract infections. This study is being conducted under a grant from the Eli Lilly Pharmaceutical Corp., and in conjunction with the Infectious Disease Division of the Hospital.

Approximately 20 patients, ranging in age from 1 to 30 years, will be studied. The patients will be tested prior to drug therapy, between the third and last day of therapy, and 1 to 3 weeks following termination of therapy. Hematologic, renal, and liver changes following drug therapy are being monitored by the Infectious Disease Division.

Vicon Purchases Plant Facilities

Chauncey Hewitt, President of The Vicon Instrument Company announced the acquisition of the complete plant facilities by the new owners of Vicon.

"In January 1975, it was announced that four well-known people in the hearing aid industry...James Nunley, Ron Morgan, Marvin Pigg and myself...had purchased Vicon. One short year later, almost to the day, we are pleased to announce that the new owners have also acquired the complete property and plant facilities from Baldwin Industries of Houston, Texas," announced Mr. Hewitt.

"In line with our future growth, it appears to be a good business decision to own the complete facilities which will enable us to grow more rapidly and modify the facilities to our future needs," commented Jim Nunley, Vice President of Vicon.

The plant, which was built to Vicon specifications seven years ago, is one of the most modern self-contained facilities in the industry today. Located at the foot of Pikes Peak in Colorado Springs, it was designed to include many facilities not normally found in hearing aid manufacturing. The plant includes complete "clean-room" facilities for the manufacture of hybrid integrated circuitry, a complete machine shop for tool and die

making as well as injection molding and rubber molding facilities. Its unique 1,000 sq. ft. sound treated anechoic chamber is one-of-a-kind in the industry and provides excellent facilities for sophisticated design and engineering capacities.

"We are not only pleased with this acquisition but proud enough to want to 'show it off,'" said Mr. Hewitt. "I would like to throw out an offer to anyone in the industry...if you find yourself in Colorado Springs, stop in and have lunch with us and we'll provide a complete tour of 'our new facilities.'"

And Then There Are Ear Plugs

Dr. Morton Corn announced on the June 18 NBC "Today" Show that there are now more figures from the BBN study on the economic impact of the 90 and 85 dBA noise standards. It would cost industry \$10.5 billion to comply with a 90 dBA standard, and once that has been done it would take \$8 billion more to reduce to an 85 dBA standard.

But listen to this: there is also a "low-cost option" that would cost \$43 million per year—little ol' ear plugs, no less. And we thought all along that ear plugs were mandatory regardless of what standard was adopted. Certainly they are mandatory for the work areas that exceed 90 dB, or whatever standard is ultimately chosen. It's nice to know how much they cost.

The BBN report cost the government \$150,000.00 Dr. Corn stated.

Tennis Anyone?

There will be an informal tennis tournament Oct. 6 and 7 at Las Vegas in conjunction with the O&O meeting. Men's singles and doubles, mixed doubles and women's singles and doubles will be played, and trophies awarded. If interested, write M. Downs for information.

ARTICLE and BOOK REVIEWS

"Early Identification of Hearing Loss." Editor, George T. Mencher, 1976, S-Karger, Basel, [Switzerland], Arnold-Bocklin-Strasse 25. \$19.00.

This book contains the proceedings of an international conference aimed at bringing together current thought on early detection of deafness. The conference was hosted by Dr. George Mencher in Halifax, Nova Scotia, under a grant from a philanthropic branch of the Benevolent and Protective Order of Elks of Canada. The participants represented the countries of Italy, Israel, Poland, Sweden, Canada and the United States.

There are great advantages in a privately funded conference such as this one. It permits an interchange of viewpoints and expertise that would take years of publications and private communications to accomplish. It gives a lead of several years to the dissemination of information on the latest methodologies and opinions. The private support permits expeditious handling and scheduling. And there seems to be at such meetings an informal camaraderie that leads to openness.

The book begins with the recommendations of the conference. Their scope is world-wide and comprehensive. All countries are abjured to provide programs for neonatal and older infant screening. The implementation of an efficient High Risk Register is the first priority. A behavioral screening test specifying arousal from sleep is allowed as a supplement to the Risk Register. Health Care systems are asked to provide for hearing testing later in infancy, in order to identify both ear disease and hearing loss. Hearing, speech and language should be evaluated at two years of age. The conference asks the World Health Organization and other Health Agencies to offer inter-disciplinary training courses on the methods to accomplish the stated goals.

The papers which follow are by people who have devoted much of their lives to the study of hearing loss and its identification. To mention a few, George R. Fraser, the dean of geneticists in hearing loss presents a classic discussion of genetics. He appeals for careful identification at birth as a possible beginning for efforts of preventing those genetic hearing losses which seem to develop after birth.

Objective measures of testing hearing are discussed by A.J. Derbyshire (Acoustically Evoked Potentials); S.E. Gerber (Auditory Cardiovascular Response); R.F. Naunton (Electrocochleography); and R.W. Keith (Impedance Measures).

Our horizons are considerably broadened by the reports from different countries on what kinds of programs have been developed under their particular circumstances. In Israel, where almost all infants and children are given health care in the state's public health clinics, it has been possible to demonstrate effective universal screening beginning at 5 months. Mrs. Lilly Tell and Dr. M. Feimesser describe their well-designed study that is a

model of investigative reporting of this type. Also from Israel is a report on automated screening by Dr. Altmann of Haifa. In Sweden and Poland it is also possible to reach most of the infants and children in the public health clinics. Dr. Borkowska-Gaertig of Warsaw describes screening beginning at 8-12 months, and Dr. Stensland-Junker of Stockholm presents her Communication screening project for 7-month old children. Dr. Rossi of Milan gives the only report of an exclusively observed behavioral testing project on newborns and recommends the continued use of this technique. Programs on this continent are described by McCulloch of Nebraska, Alexander and Zink of Canada, Simmons of Stanford, and Downs of Denver.

Dr. Bess of Central Michigan University describes a survey of pediatricians' attitudes toward newborn screening; most were willing to support at least a High Risk program. Other pertinent papers are presented by Dr. Phillip Peltzman, Dr. Cancel de Irizarry, and by Dr. Aram Glorig with Gary Curtis. This last paper describes a workable plan for developing a state-wide identification program, based on a legislative proposal in Texas.

Not since the Toronto conference of 1962—also a privately endowed meeting—have so many people from different countries been brought together for mutual dialogue. The proceedings should be read by all who would like to get a world perspective on this specific health delivery problem. There is a warm and compassionate feeling in these papers and in the recommendations made by the participants. For anyone who cares about early identification there is good reading and widened perspectives in this book.

IF A CHIMP CAN LEARN SIGN LANGUAGE

by Rachel Mayberry
School of Human Communication
Disorders, McGill University
Montreal, Quebec, Canada

After one of those simply awful titles that seem to be "in vogue" these days, the reader is treated to a relatively good account of the various sign systems currently being used in the United States. The author analyzes American Sign Language (ASL), Seeing Essential English (SEE-1), Signed Exact English (SEE-2) Signed English, and the Linguistics of Visual English. A disappointingly small amount of time was given to fingerspelling, apparently because of the author's expressed belief that fingerspelling is merely "writing in the air", an evaluation this author takes issue with, but will not go into this review.

The second section of the article concerns itself with the actual use of sign language systems in working with nonverbal individuals, for whom attempts to establish oral language have failed. This was a somewhat disappointing section that could have been made stronger had the author presented some examples

of individuals who had experienced a measure of success in developing some language. However, the article should stimulate many clinicians to explore these interesting alternate systems currently in use with the deaf.

"Mainstreaming: Format or Quality?"

Richard G. Brill, Ed.D.
California School for the Deaf
Audiology and Hearing
Education, Vol. 2, No. 3, 1976

One cannot pick up a magazine today, whether it be a professional journal or Cosmopolitan, without reading that mainstreaming it here, and indeed, that it is a solution to the problems of the handicapped. Least restrictive environment and due process were terms that, until recently, had meaning only to attorneys.

Today, these and other vocabulary are central to the happenings in education. Dr. Brill's discussion of mainstreaming is one of but two articles I have read in the past year and a half that offers serious questions about our carte blanche application of this concept to all types and degrees of handicapping conditions.

Superintendent Brill's article begins with the history of mainstreaming, dating back to the classic "Mills versus the Board of Education" in Washington, and "The Pennsylvania Association for Retarded Citizens versus the Commonwealth of Pennsylvania." It points out how concepts developed, not as a result of our own thinking and planning in education, but as a result of court actions brought against schools by parent groups. (Although today, you would think, to listen to educators, that education was the plaintiff INSTEAD of the defendant in these suits. Editor)

A particularly important aspect of this article is the statistical data on the incidence of deafness. It is material that has always been readily available, but which in recent years, has been overlooked or outright ignored by both educators and the courts. Dr. Brill makes a strong case for realistic program planning for the deaf in the centralized school environment. In another section of the article, Brill makes the point that hearing handicapped children are not best served in the least restrictive environment, but best served in a situation with fully trained teachers, who are appropriately supervised by master teachers, and where additional services are available. In the case of deaf youngsters, this is most often in the residential school.

I cannot recommend this article too strongly to those colleagues who are responsible for

placement decisions on hearing handicapped children.

"Cochlear Implants;
Development of an Idea",
Ear Research Institute and
Walt Disney Hearing
Rehabilitation Research Center
House, W.F., ed.,

The goal of this work is clearly stated at its outset; "This monograph details the events and results of fifteen years of work with the cochlear implant at the Ear Research Institute." The authors achieve this goal admirably. First, they chronicle the development of cochlear and eighth nerve stimulation from early reports to present day. They review their own experiences leading to the present use of a single wire electrode and induction coil. Case selection, pre-implant testing and interview, post-implant studies, and rehabilitation procedures are then presented. At the ERI these steps are taken by a team consisting of an otologist, a speech pathologist, an audiologist, an engineer, two psychologists, and a psychological assistant. Chapter IV outlines their initial efforts to "track the subjects psychological function through time." Last, the monograph defines future objectives of the cochlear implant project.

This monograph, without overstating the fact, portrays the dedication and intensity with which the Ear Research Institute has undertaken this project. In light of this devotion to their goal and the controversy which revolves around the entire subject, it would seem natural if the authors used this monograph as a platform to defend their position or to answer criticism. They refrain from doing so. Rather, they stick closely to their original goal of relating their experiences with implants. As a result, the reader is provided an informative and readable article. They precisely document their results and set down some realistic objectives for the future.

This monograph is recommended for anyone interested in the subject of cochlear implants.

Donald W. Goin, M.D.

"The Call Girls"
by Arthur Koestler,
Dell Publishing Co.,
1 Day Hammerskjold Plaza,
N.Y.C. 10017
\$1.75 [paper-back]

Sorry, boys, this provocative title is completely misleading. The Call Girls of the title are all of us who move from conference to conference, symposium to symposium—at the drop of a telephone ring. As one of the participants at the book's symposium says "I am an academic Call Girl. We are all Call Girls...

It becomes a habit, maybe addiction. You get a long-distance telephone call from some professional busybody at some foundation or university..."

The place is Switzerland. The meeting is on "Approaches to Survival"—a conference of leading scientists who are charged with composing an "Einstein letter" to the President. The purpose is to solve the world's problems of over-population, diminishing resources, and recurrent wars. Like all of us, the participants know each other from frequent similar meetings in the past and look forward to meeting more in the future. There are the usual distinctive types that are familiar to us: The Call Girl Laureate who has received all the honors that institutions, governments and universities can bestow on him and is insufferably outspoken; the "enfant terrible" who is an exhibitionist but a brilliant scientist; the Nobel prize winner who is a Lolita-chaser; the impassioned visionary who thinks he can save the world; the "bright but bitchy" woman scientist who calls the men's wives "dowdy, poisonous, and always tired,"—and many more.

What is fun about this book is the satire on meetings of this kind: "They liked to cram forty to fifty papers into a five-day conference, which put the participants into a condition not unlike that of punch-drunk boxers, and left no time for discussion, although the discussions were the declared primary purpose of the whole enterprise."

And on late arrivals, "The other absentee was Bruno Kaleski, last year's winner of the Nobel Prize for Peace; he had wired that he was delayed by urgent business and would arrive later in the morning. That sort of thing, too, inevitably happened among the Call Girls. Some were always late, some had to leave before the end of the conference, some came only for one day, delivered their papers, collected their fee, and dashed off again."

Everything is described in accurate detail: the ritual cocktail parties; the paraphrasing of the same talks that the speaker has given at several previous conferences; the tunnel vision of each participant who believes only HIS approach can solve the problems; the non-stop speaker and the trouble in readjusting physiological clocks to local time and food.

The Call Girls "looked up themselves as a traveling team of professional wrestlers, who are familiar with one another's antics and go through their paces each time pretending surprise and indignation at the base tricks of their opponents."

The symposium goes the way of all symposia: everyone has his say; no one listens; and nothing comes of it. But what were you expecting? They would save the world? Better you just enjoy this book.

FILMS

Operant Audiometry with Severely Retarded Children"
Color, 16 mm
Rental\$15.00
Purchase\$100.00

Robert T. Fulton,
Joseph E. Spradlin,
Lyle L. Lloyd

Purpose: To demonstrate the application of basic operant conditioning principles in testing the hearing of severely retarded children.

Audience: Audiologists, Psychologists, Teachers, College Students, Behavioral Scientist and others in Developmental programs.

Description: As a demonstration of positive reinforcement in testing the hearing of a severely retarded person, this film traces the progress of a 13-year-old boy through several clinical sessions designed to detect and diagnose hearing impairments. It demonstrates how the child is conditioned to wear a headset and how reinforcement techniques are employed to train the child to respond to auditory stimuli.

"Hearing Assessment for the Young and Difficult-to-Test"

Color, 16 mm
Rental\$10.00
Purchase\$100.00

Robert T. Fulton

Purpose: To demonstrate the use of operant audiometric techniques in the hearing assessment of a variety of difficult-to-test persons.

Audience: Parents, Administrators, Teachers, Audiologists, Psychologists, Students, Behavioral Scientists and others in developmental programs.

Description: The testing of a number of individuals who are considered difficult to test is demonstrated during the course of this film. The application of the operant paradigm is featured. Through the use of clinical sessions, the film depicts a broad range of conditions which make hearing evaluation difficult. The operant procedures permit testing despite those conditions.

"Temporal Parameters of Auditory Stimulus-Response Control"

Color, 16 mm
Rental\$15.00
Purchase\$100.00

Robert T. Fulton and
Joseph E. Spradlin

Purpose: To illustrate a procedure to insure accurate data in auditory threshold evaluations of severely retarded children.

Audience: Audiologists and other speech and hearing specialists.

Description: The test demonstrated in this film presents signals in random or alternating order with nonaudible control periods. Intervals between auditory signals are systematically varied. Programming safeguards and their effects on test results and subject behavior are illustrated by continuous, realtime animation superimposed over film of a subject being tested. The animation reflects, second-by-second, the variations of the testing program as it affects, and is affected by, the subject.

"Developing Auditory Stimulus-Response Control with Young Children"

Color, 16 mm
Rental\$15.00
Purchase\$100.00

Robert T. Fulton,
Pamela A. Gorzycki,
Wilma Hull

Purpose: To demonstrate the behaviors of very young children and how these behaviors are brought under stimulus-response control to achieve hearing assessments.

Audience: Audiologists, Physicians, Psychologists, and others concerned with the evaluation of handicaps in very young children.

Description: Auditory stimulus-response control is a critical dimension in the testing of children two years of age. Children may have suspected hearing losses, but they may be too young to respond to spoken instructions. Their behavior may be directed toward attempts to escape from the testing environment rather than toward cooperating with the audiologist. If the child can be placed under stimulus-response control, the auditory measurement becomes rather routine. This film demonstrates techniques used to obtain reliable bilateral auditory data from children as young as nine months.

"List of Personal Hearing Protection and Attenuation Data"

H.E.W Publication
No. [NIOSH] 76-120
Division of Laboratories and
Criterion Development
Cincinnati, Ohio 45202

A listing of suppliers of ear protection devices, models and types of ear protectors, average attenuation values at test frequencies 125-8000 Hz, test standards and testing laboratories. Advice is given as to how to choose ear protectors, and how NIOSH calculated the attenuation factors for ear protectors.

Hearing Aid Specs Nearing Approval

The proposed specification standards on hearing aids outlined by Sam Lybarger in the January "Corti's Organ" are moving steadily toward eventual approval by the Federal Food and Drug Administration. The present status of the standard is that it has been approved by the Acoustical Society of America Committee of Standards and has been forwarded to ANSI for consideration.

Once ANSI approval has been received, the standard will be published—possibly in late summer or fall.

An April 21 excerpt from the Federal Register explains the development of these standards:

"On March 10, 1975, the FDA Panel on Review of Ear, Nose and Throat Devices made a preliminary recommendation that hearing aids be classified as devices for which performance

American Audiology Society members, Jakob Skadegard, President of Oticon Corporation USA, and Jerry Northern, Ph.D., of the University of Colorado Medical Center share a few social moments at the UNESCO Building in Paris. Skadegard holds the International Trophy awarded to the Oticon Foundation.

standards will be required after enactment of proposed medical device legislation (S. 510, H.R. 11123). Of all devices placed in the standards category by the Panel on Review of Ear, Nose and Throat Devices, hearing aids were ranked as the first priority for the establishment of standards. FDA has been working with interested persons to develop a standard for hearing aids. At

FDA's suggestion, the American National Standards Committee on Bioacoustic (S-3), through its Working Group on Hearing Aids (S3-48), has developed a draft standards, known as S 3.22, 1976,

American National Standard for Specification of Hearing Aid Characteristics, which would specify uniform methods for testing and measuring the electroacoustical characteristics and properties of the hearing aid

(Ref. 10). The standard was based in part on earlier American National Standards (Ref. 11 and 12). Although these proposed regulations do not adopt any minimum or maximum performance requirements for hearing aids, under proposed 801.420 (c) (3), the technical data that would be required in hearing aid labeling would be determined in accordance with the test methods of the standard S 3.22, 1976."

Bringing Home The Bacon

It seems you just can't trust anyone anymore. Politicians, law enforcement officers, lawyers, doctors, and even clergy have earned a raised eyebrow for themselves. People are just plain tired of being deceived. I guess Watergate, Vietnam, Cambodia and other fraudulent deceptions have numbed us, and, it seems to me, scientific reporting has fallen prey to the same evil. Our journals are full of misleading statistics, confusing data, unjustified conclusions, and fuzzy logic, despite the best intentioned editors and the most wary of referees. In a time when resources must be used most efficiently and expeditiously, most investigators should be asking themselves some pretty basic questions—Am I really contributing something? Have I added anything to what's already known? Does what I'm reporting make sense?

Perhaps we can learn something from Sir Francis Bacon, who, in 1620 described a system of inductive reasoning whereby facts are observed, catalogued and linked. This milestone in the development of scientific thought deserves renewed interest amongst those of us called "researchers". Too often, the desire to produce meaningful research is clouded by one's ego and prejudices. Let's face it. Francis Bacon was right. That system which divorces itself from bias and unproven deductions serves science best. That framework which helps readers apply scientific observations to individual patients serves the latter best. It's time we redefine our investigations and scrutinize their worth. In short, we need to call a moratorium on fat and concentrate more on the bacon.

Arden D. Meyers, M.D.

Be Kind to Neighbor But Stay Out of Noise

It has been established that people lose their Good Samaritan traits in the presence of a noisy environment. Two psychologists, as reported in the Journal of Personality and Social Psychology (Vol. 32, No. 4), set up experiments to determine the difference between people's behavior in quiet and in noise.

52 student volunteers were each made to wait in a quiet room (48 db) to be called for an expected experiment. The experimenter was waiting in the same room with a pile of books on his lap. When he got up, he dropped the books. Three-quarters of the 52 students helped pick up the books in the quiet situation. However, only half that number helped with the books when noise of 85 dB was introduced into the room.

A similar street experiment was set up, with a man carrying two large boxes filled with books from his house to his car. As a potential subject walked by, the man dropped several books, and then spilled more when he reached down. When the noise level was measured at about 50 dB, 20% of 80 random subjects stopped to help, and this number was increased to 80% when the book-carrier wore a cast on his

arm. But when a lawn mower nearby produced 87 dB of noise only 10% helped the normal book-carrier and 15% helped the man with the cast.

There go the nobler instincts of man, drowned out by a high environmental noise level. EPA, take note.

Children Are A Noise Hazard

It may come as no surprise to parents of vocal children to learn that their little ones can (and do) produce dangerous noise levels. A 12-year old girl uttered screams of 122 dBA, according to an article in the "New Scientist" (Vol. 68, No. 980). The researchers clocked the mean level of 200 screeches by primary school children at 114 dBA on the sound level meter.

The Environmental Protection Agency should be alerted to this new health hazard. We conjure them to regulate the vocal exuberances of young children just as other environmental noises are being regulated. Some retooling by laryngologists may be the first line of defense against this dangerous occupational hazard for parents.

NEWS FROM ALASKA

Rural Alaska has often been identified as an area of the United States with the highest incidence of otitis media. This has been documented on numerous occasions including studies by Maynard & Hammes (1970) and Reed (1965). Unpublished (audiometric and impedance) data collected by the Communicative Disorders Program of Alaska Department of Health & Social Services in 1975 revealed that preschool children tested demonstrated 20% to 33% with either type B tympanograms (middle ear effusion) or tympanic membrane perforations (% vary - depending upon which section of the State is surveyed). The predominant cause of Type B impedance findings is believed to be serous otitis media. Type C (eustachian tube obstructions) impedance findings were recorded in 22 to 27% of this population.

In addition to its ongoing programs statewide, the CDP is monitoring intensively the status of Headstart children in 11 rural Alaska villages in an area surrounding the S.W. Alaska community of Bethel. Over a period of one year these children will receive 4 audiological evaluations consisting of pure tone and impedance audiometry. The final two tests will be conducted in the fall of 1976 and will be supplemented by ENT exams and the necessary medical and surgical management. This project is a joint venture of the CDP of the Department of Health and Social Services, Alaska Headstart, the Bethel PHS Service Unit Hospital and a private ENT physician.

This study should provide some baseline information concerning the duration and variability of serous otitis in addition to providing needed audiological and ENT care to these remote villages.

The CDP audiologists responsible for S.W. Alaska are Mr. Bill Orr and Mr. Carl Dixon. David R. Canterbury, Ed.D., is the Chief of the Alaska Communicative Disorders Program.

The Alaska State Department of Education initiated the Alaska Child Find Project during 1975. The purpose of this project is to identify, locate and begin educational services to all out-of-school handicapped children and youth. In Alaska, handicapped children from 3-19 years of age are included in the public school educational domain.

A public awareness campaign was initiated in order to increase parental and professional awareness of the educational services available to handicapped children. Handicapping conditions may include mental retardation, visual handicaps, blindness, hard of hearing, deafness, multiple handicaps, physical handicaps, emotional handicaps, speech impairments, and specific learning disabilities.

Because Alaska Child Find is an on-going project with no termination date, physicians, public health nurses, and other health and educational personnel are encouraged to continue to make

every effort to work with local school districts in identifying unserved handicapped children and youth. Parents are also encouraged to initiate the process of obtaining education services for their child. Parental participation is one of the most important factors involved in serving handicapped children.

Sharon L. Murray, Ph.D., is the new director of the speech and hearing center associated with the Alaska Crippled Children and Adults (ACCA) in Fairbanks, Alaska. Upon returning from a recent field trip to the interior villages and schools, she reviewed the role of the center in providing speech and hearing services to the rural areas. She was asked to comment about the results of this evaluation and these edited comments are offered for publication.

A BRIEF LOOK AT PROBLEMS INVOLVED IN MANAGEMENT OF COMMUNICATIVE DISORDERS IN RURAL ALASKA AND THE ROLE OF THE NON-PROFIT, FREE-STANDING CLINIC

THE DILEMMA:

The problems encountered in serving the rural areas of Alaska with speech and hearing services are not only complicated by inaccessibility of the villages and the population but by the varieties of cultural entities which exist. Past efforts have assumed that evaluation and remediation of hearing and speech language problems are, indeed, desirable. Historical acceptance of middle ear pathology and multiple dialects of several distinct Eskimo and Indian cultures all weigh on this assumption.

Otitis media has been acknowledged for the past ten years as one of the State's primary health problems in the native population and it logically follows that all areas of speech and language development would be affected.

PRESENT PROGRAMS:

The resources and expertise of the free-standing speech and hearing centers, the physician, the itinerant public health nurses and health aides, the native health services, Rural-Cap's Head Start Program, Department of Education, State Health Communicative Disorders Program and local schools are required to overcome some of the physical and cultural differences within Alaska to provide services for communicative disorders.

The two non-profit private centers offer services on a two fold approach to isolated villages: (1) Families referred from local villages are flown into the centers for intensive work, sometimes remaining two to three weeks; (2) Clinicians fly to the villages, usually remaining several days mostly due to lack of available return flights. Workshops and institutes for training

aides and teachers have also been accomplished both at the center and in the villages.

FUTURE TRENDS:

The role of the non-profit private clinic toward effective program management within the villages could go in one or more of three major directions in the northern interior region of Alaska. The first would be as a consultant; that is, working with a "speech generalist" who is either located in a village or traveling between other villages similar to the itinerant speech clinician in the public schools. As a consultant, the center would provide assistance with screening and in-depth diagnosis, behavioral planning and follow-up. All this will be accomplished with the consultant visiting the respective villages.

A second direction that is currently being considered is a contract between school districts and the center to provide an itinerant speech pathologist. This person's responsibility would be the screening, evaluation program planning and monitoring of children with communicative disorders in the various villages. In contrast to the itinerant "speech generalist", there would be a contract arrangement for a salary with the clinic and, therefore, the clinic's responsibility for quality management.

A third direction should occur regardless of who serves the population directly, and that is on-the-job training of village health and teacher aides and preschool teachers. Periodic workshops held at the clinic would supplement this training and allow group program development. This would allow services to be more tailor made to the particular needs within each village setting.

—Sharon L. Murray, Ph.D.
Director
Alaska Crippled Children and Adults
Speech and Hearing Services
1020 Barnette Street
Fairbanks, Alaska 99701

The staff at the Alaska Native Medical Center (ANMC) have observed that the children exhibiting auditory discrimination disorders prior to undergoing middle ear surgery often continue to exhibit this disorder after restoration of normal hearing acuity.

An on-going study is attempting to determine the effects of auditory discrimination training upon children's auditory function following surgery. The hypothesis being that auditory discrimination training following middle ear surgery will result in a statistically significant improvement in auditory discrimination skills when compared to a similar group of children receiving no training in auditory discrimination.

The children selected are those admitted to ANMC for middle ear surgery and who range in age from 6 to 18 years. In addition to the usual array of audiometric tests, the Goldman-Fristoe-Woodcock Test of Auditory Discrim-

ination (GFWTAD) is utilized to assess auditory discrimination skills. Complications were initially encountered when it was found in the pre-test procedures that the Native children could not identify some of the concepts because of the unfamiliarity with the picture stimuli in the GFWTAD. For example, many of the children had never been exposed to such concepts as "cab" or "big" as they had no exposure to taxis or elephants.

The investigators received authorization from the publishers of the GFWTAD to modify the test to meet the demands of the cultural background of the children. The services of a linguist was contracted to substitute the unfamiliar concepts with those more recognizable by the Native children and yet retain the desired phonetic integrity. An artist was then employed to modify the pictures.

The experimental group will each receive daily individualized instruction in auditory discrimination while the controls will receive daily individualized instruction in an area determined not to be associated with auditory discrimination. Amplification by use of auditory training units will be utilized and, prior to release from ANMC, post-testing status will be done by a qualified person who is unaware of which group the child had been assigned. If a statistically significant difference is observed in the measured

changes in auditory discrimination skills of the experimental and control group, training in auditory discrimination will be included in the curriculum of the ANMC school.

The University of Alaska, in conjunction with the Alaska Speech and Hearing Association is offering a graduate level credit course, June 23-27, at the University of Alaska in Fairbanks. The course, Auditory Processing: Assessment and Remediation, will be taught by Katherine G. Butler, Ph.D., California State University (San Jose) who is presently director of the Language, Speech and Hearing Center and associate dean of Graduate Studies and Research at that institution.

The course, directed to speech pathologists, audiologists, teachers of the hearing impaired, reading teachers and teachers of special education, will provide basic theoretical and practical information regarding auditory processing as it relates to language and learning disorders. Specific auditory perceptual skills will be identified which are thought to affect language learning and academic achievement.

Name This Famous Audiologist

[See Answer on Page 11]

Kent Hearing Aid Collection Available

The Speech and Hearing Clinic at Kent State University houses what is undoubtedly the largest collection of hearing aids in the world. This hearing aid museum has more than two thousand different hearing aids on display. There are non-electric models, carbon aids, vacuum tube instruments, transistor models, and the latest miniature devices.

In addition to the hearing aid there is an archives comprised of hearing aid patents from the United States and abroad, technical data sheets about specific hearing aids, advertising materials, photographs, and historical documents. There is also a large collection of books, pamphlets, and article reprints relating to amplification. The hearing aid museum and archives is a veritable goldmine for individuals desiring to do historical or technical research on hearing aids.

The museum and archives are open for use by anyone interested in hearing aid research. At present there is no staff time available to search for specific documents or to answer detailed questions by mail, but scholars are invited to visit Kent State University to use the materials.

Kenneth W. Berger, Ph.D., is the curator of the Kent State University Hearing Aid Museum and Archives.

Calendar of Events

JULY

5-9

National Association of the Deaf Biennial Convention, Shamrock Hilton Hotel, Houston, Texas.

5-11

Fifth Symposium on Middle Ear Surgery at Theodor Heuss Academy and Municipal City Hospital, Gummersback (Cologne), West Germany. Write to: Claus Jansen, M.D., Otolaryngology Department, Municipal City Hospital, 527 Gummersback 1, West Germany.

12

Audiometric Technician Refresher Course, Boone, North Carolina. Fee: \$85.00. Contact: Oto-Data, Inc., 842 N. Highland Avenue, N.E., Atlanta, Georgia 30306.

12-14

Audiometric Technician Training and Certification Course, Boone, North Carolina. Fee: \$185.00 (see above).

12-16

7th Annual Industrial and Product Noise Control Institute. (With the cooperation of Bolt, Beranek and Newman, Inc., Union College, Schenectady, New York.) Registration fee: \$475.00. Graduate Studies and Continuing Education, Wells House, 1 Union Avenue, Union College, Schenectady, New York 12308.

12-23

61st annual course in Head and Neck Anatomy and Clinical Otolaryngology, Indiana University.

26-30

Industrial Noise Control Seminar. Fee: \$275.00. Contact: B&K Instruments, 5111 West 164 Street, Cleveland, Ohio 44142.

AUGUST

1-5

Seventeenth Annual Frederick T. Hill Seminar in Otolaryngology, Dean Medical Center, Thayer Hospital, Waterville, Maine. Write to Robert H. Kams, Division of Special Programs, Colby College, Waterville, Maine 04901.

16-18

Audiometric Technician Certification Course. Contact: Dr. Donald Hogan, Townhouse Condominium, Ste. # 2, Guayanilla Final, Rio Pedros (San Juan), Puerto Rico.

19-21

Audiometric Technician Certification course. Fee: \$175.00. Contact: Dr. D.A. Metz, American Industrial Hearing Services, 2475 Esat 22nd Street, Cleveland, Ohio 44114.

24-26

Community Noise Seminar. Fee: \$125.00. Contact: B&K Instruments, Inc., 5111 West 164 Street, Cleveland, Ohio 44142.

SEPTEMBER

7-9

Industrial Hearing Testing Workshop. Fee: \$250.00. Contact Center for Continuing Education, Emerson College, 148 Beacon Street, Boston, Massachusetts 02116.

13-16

Human Acoustics Seminar. Fee: \$250.00. Contact: B&K Instruments, Inc., 5111 West 164 Street, Cleveland, Ohio 44142.

16-18

American Neurotology Society course: "Update Neurotology" at Lenox Hill Hospital. Registration fee: \$100. Address inquiries to: Kenneth H. Brookler, M.D., Lenox Hill Hospital, 100 East 77th Street, New York, New York 10021.

30-Oct. 2

A New Advanced Course and 3rd International Symposium in Impedance Audiometry, Philadelphia. For information: Educational Services Division, American Electromedics Corporation, 145 Palisade Street, Dobbs Ferry, New York 10522.

OCTOBER

5

Annual Meeting of American Audiology Society, Las Vegas, Nevada.

5-6

Research Forum of the Association for Research in Otolaryngology, Las Vegas Convention Center, Las Vegas.

6-10

1976-Annual Meeting of O&O, Las Vegas, Nevada.

9-24

16 Day European Study Tour, Denmark to Italy.

18-21

International Audiology Society, Florence, Italy.

21-24

National Hearing Aid Society Annual Meeting, Palmer House, Chicago.

30-31

Western Regional Auditory Approach Conference: The Hearing-Speech Chain - A.G. Bell and Listen Foundation, Sponsors; Dr. Mark Ross, Leahea Grammatico, speakers. Hilton Hotel, Denver, Colorado.

NOVEMBER

16, 17, 18

Annual Meeting of Society for Ear, Nose and Throat Advances in Children. New Orleans, Louisiana Maison Dupuy Hotel. Write to Dr. Basharat Jazbi, The Children's Mercy Hospital, 24th at Gillham Road, Kansas City, Missouri 64108.

16-19

Acoustical Society of America, San Diego, California.

20-23

American Speech and Hearing Association, Houston, Texas.

1977

FEBRUARY

20-24

Ear Surgery Course, J. Brown Farrior, M.D., Tampa, Florida.

MARCH

5-12

Medical Audiology Workshop, Vail, Colorado. For information write to: Box B210, 4200 E. 9th Avenue, Denver, Colorado 80220.

Answer: Jerry Northern in 1966, signing for a program for the deaf.

Sentac to Meet In New Orleans

The Society for Ear, Nose and Throat Advances in Children will hold its annual convention in New Orleans, Louisiana November 16, 17, and 18, 1976. The convention will be held at the Maison Dupuy Hotel in the French Quarter. The program will be comprised of participation by the four primary disciplines represented within SENTAC; otolaryngology, pediatrics, audiology and speech pathology. Several recreational

Crosby Joins Advisory Board

Norm Crosby, as many people know, has a hearing impairment—the result of a wartime injury. "I make no bones about the fact that I have a hearing loss and that I wear hearing aids," says Crosby, who takes every available opportunity to talk about his problem, and the help he receives from hearing aids, on television and in his personal appearances.

In addition to his membership on the Better Hearing Institute Advisory Board, Crosby stars in BHI TV and radio public service announcements and appears in the Institute's "They Overcame Hearing Loss" celebrity booklet. He is the first person to have received BHI's Better Hearing Achievement Award for his charitable work in aiding people with a hearing deficiency.

EUROPEAN STUDY TOUR DEADLINE

The final deadline for reserving space on either of the European Study Tours is August 1st. Details are in Corti's Organ Vol. 1, Numbers 1 and 2. Send your \$100.00 refundable deposit to:

AMERICAN AUDIOLOGY SOCIETY
c/ o FIRST TRAVEL SERVICE
1st NATIONAL BANK BLDG.
ONE CENTRAL AVENUE
BROWNWOOD, TEXAS 76801

PROGRAM

1976 ANNUAL MEETING

AMERICAN AUDIOLOGY SOCIETY

Tuesday, October 5, 1976

PLACE: ROOMS H 51-56 [Rooms 1-6]
Las Vegas Hilton Convention Center

REGISTRATION:

Members \$5.00
Non-Members \$8.00

Begins 8:30 a.m.

8:30-12:00 p.m. EXECUTIVE COMMITTEE MEETING
12:30-12:35 p.m. INTRODUCTION & AWARD-Pres. W.D. Ward
12:35-2:30 p.m. FIRST RAYMOND CARHART MEMORIAL
LECTURE by JAMES F. JERGER, Ph.D.
2:30-2:45 p.m. COFFEE BREAK
2:45-5:07 p.m. CONTRIBUTED PAPERS
5:10 p.m. - til BRIEF BUSINESS MEETING

[Because Monday, October 4th, is Yom Kippur, the public portion of the meeting has been compressed into approximately 5 hours of the afternoon of October 5th. This will, hopefully, allow our colleagues of the Jewish faith to use Tuesday morning as travel time to reach the meetings.]

CONTRIBUTED PAPERS

HEARING AIDS

2:45-2:57 p.m.

Relationship of Performance Characteristics in Hearing Aids to Cavity Volume.

Robert E. Jirsa, Ph.D.
Thomas W. Norris, Ph.D.

2:58-3:10 p.m.

The Effect of In-the-Ear Hearing Aid Canal Length on Frequency Response.

John C. Sinclair, Ph.D.

3:11-3:23 p.m.

Increasing Acoustical Efficiency with In-the-Ear Hearing Aid Fittings.

T.S. Griffing, Ph.D.
D.A. Preves, Ph.D.

PERIPHERAL AUDITORY & VESTIBULAR SYSTEMS

3:24-3:36 p.m.

Estimation of the Stapedius Reflex in Industrial Hearing Loss.
P.W. Alberti, M.B., Ph.D., F.R.C.S.

3:37-3:49 p.m.

The Effect of Ventilation on Middle Ear Volume and Eustachian Tube Function in Secretory Otitis Media.

H. Bryan Neel, III, M.D.
Lawrence W. Keating, Ph.D.
Thomas J. McDonald, M.D.

3:50-4:02 p.m.

Air Calorics: A Technique and Results

Jaime T. Benitez, M.D.
Kenneth R. Bouchard, M.A.
Yong K. Choe, B.A.

4:03-4:15 p.m.

Natural History of Idiopathic Sudden Hearing Loss

F. Blair Simmons, M.D.
Douglas E. Mattox

4:16-4:28 p.m.

N1 Latency of the Human Whole-Nerve Response to Filtered Clicks.

Stanley Zerlin, Ph.D.
R.F. Naunton, M.D.

CENTRAL AUDITORY SYSTEM

4:29-4:41 p.m.

Effect of Peripheral Hearing Loss on Central Auditory Tests

Gerald E. Miltenberger, M.A.
Gerald J. Dawson, M.S.
Anthony N. Racia

4:42-4:54 p.m.

Rapidly Alternating Speech Perception: A Test of Brain Stem Dysfunction

George E. Lynn, Ph.D.
John Gilroy, M.D.

4:55-5:07 p.m.

Dichotic Listening Performance in Partial Split-Brain

Martin L. Lenhardt, Ph.D.

The Experts Discuss Myringotomy
& Tube Placement in
THE INTERROGATORY

AAS Annual Meeting Airs Scientific Topics

A lively, rapidly-moving program marked the 1976 Annual gathering of the A.A.S. in Las Vegas. Chuck Berlin organized and chaired a meeting that was given A-ratings by all attending. More than seventy members listened to a memorable address by James Jerger. His talk represented the first annual Carhart Memorial Lecture, established to honor the memory of Raymond Carhart. In it he presented nostalgic views of Dr. Carhart and the Northwestern Clinic of 30 years ago.

Jerger stated that Carhart invented speech audiometry almost single-handed. At De Shon Hospital in the late war period Carhart adopted the Harvard

Psycho-acoustic Lab speech material for use in hearing aid evaluations. The English-speaking world still uses these materials unchanged 30 years later, indicating that Carhart was indeed ahead of his time.

At the Texas Medical Center Jerger and his associates are attempting to broaden the scope of speech reception material. They have been using synthetic sentences composed of a different order of words in a meaningless context. The subject identifies which of ten 7-9 word sentences is being presented, in a matrix of a competing message.

[Continued on page 7]

News About Members and Others

Laura Ann Wilber has been elected President of the New York State Speech and Hearing Association for 1977-78.

Jim Curran has moved to the Maico Hearing Instruments Co. as their Director of Auditory Research. His duties will be related solely to product development and research in the area of the application of hearing aids to the hearing impaired.

William J.A. Marshall has been appointed Director of the Model Secondary School for the Deaf at Gallaudet College.

[Continued on page 2]

New Organization Established for Professionals in Hearing Conservation

A new professional organization, the Hearing Conservation Association, has recently been established. Representatives from two companies currently involved in industrial audiology, Environmental Hearing and Vision Consultants, Ltd., of Syracuse, New York and Miami Hearing Conservation of Miami, Florida, met together when they recognized the need for a professional association which would serve a number of functions in this specific area. Currently, most professionals involved in industrial hearing conservation are members of individual professional associations but there is no parallel association for professional corporations or consultants who function either as members of a group or as individuals. In this regard, the Hearing Conservation Association is more like a professional

trade association rather than an association for individuals.

The specific purpose of the Hearing Conservation Association is to encourage education and to advance hearing conservation practices and procedures among professionals so engaged. One goal is to work toward the development of cooperative activities between providers of industrial hearing conservation services which would facilitate homogeneity in the quality of these services across corporate networks when individual providers have geographical limitations. This would assure an industrial purchaser of these services that the same standard of services could be obtained in any location across the country.

Letters announcing the intent to establish the organization were sent to audiologists and otolaryngologists and the Association was

officially established in June 1967. Alan Feldman, Fredric W. Pullen, II, Lennon G. Adams, Jr., and Constance H. Cabeza, are President, Vice President, Secretary and Treasurer, respectively. Other at large members of the Executive Council are William H. Call, and Don L. Wolfe.

There have been in excess of 65 responses from people in the fields of Audiology and Otolaryngology, representing professional groups (corporations) and individuals, who have applied for membership. The first meeting of the Association is being planned for February 11th and 12th, 1977, at the Marriott Hotel in Miami. Additional information may be obtained by writing to Lennon G. Adams, Secretary, Hearing Conservation Association, 309 Mercy Professional Building, 3661 So. Miami Avenue, Miami, Florida 33133.

What C.H.E.A.R. is All About

The charitable activities of an organization by the name of Children's Hearing Education and Research (C.H.E.A.R., Inc.) have recently been in the news. Corti's Organ requested the information on the goals and activities of this organization, and received the following run-down from Mr. Ben Parmer, Administrator:

"C.H.E.A.R., Inc. (Children's Hearing Education and Research) was founded in 1969 to do for the hearing impaired what was and is being done on a national level for other diseases such as Heart, Cancer, and other handicaps.

The problems of deafness and especially Nerve Deafness has received little help, interest or research from organized groups, and no organization has yet become the nation-wide organization that one can turn to for the unbiased, accurate information necessary for the parent, person involved, or even the general public, in the areas of education, scientific research, treatment and therapy.

That is what C.H.E.A.R. is all about—to force this to occur on a national level so that: (1) the urgent, vital medical research and monies necessary to find a cure for or alleviation of Nerve Deafness is available and done; (2) the persons involved can make an intelligent choice as to education; (3) the general public understands the seriousness of this tragic communicative problem, and what deafness is and what it is not; and (4) people with or without the problem can learn how to help, so that the discrimination against the deaf in the areas of research, education, treatment, and employment can be overcome.

On a purely voluntary basis, with no paid professional employees, we have given contributions that have succeeded in having other organizations committing larger sums for research in the Nerve Deafness area. One example is the Deafness Research Foundation.

C.H.E.A.R. has awarded Grants for Deafness Research to the following noted scientists and organizations:

Dr. Robert Ruben, Albert Einstein School of Medicine in New York City, for Medical Research involving cell biology and deafness.

Dr. David Hilding, New Jersey College of Medicine, for an Early Detection Deafness Research Program to determine the best device to use in a maternity hospital to screen newborn babies.

Dr. Howard House, Ear Research Institute of Los Angeles, for medical research program involving cochlear research.

Deafness Research Foundation, New York City.

In addition, C.H.E.A.R. has also awarded scholarship prizes for schools, both public and private, that have educational programs for the hearing impaired and are interested in mainstreaming education of the deaf or who specifically service hearing-impaired children.

C.H.E.A.R. issues a quarterly newsletter entitled "Hearing Research Developments", which is a digest of the latest information and developments on hearing impairment.

C.H.E.A.R. has available radio tapes which have been used as part of public service announcement programs on the leading radio stations in the United States. The purposes of these radio spot messages is to alert the general public about the problems of hearing impaired and to gather support for C.H.E.A.R. by raising research funds or allowing us to give further information about this tragic communicative disease.

C.H.E.A.R. raises funds for its varied activities in many ways.

1. Through donations by several Foundations.
2. Contributions of various organizations such as the Odd Fellows.
3. Individual contributions of friends, and businesses.
4. Localized chapter card parties, theater groups, a city charity fair, a week-end at a resort hotel, week-end journal, fashion shows, charity circus, a raffle, a Raceway night."

[Editors's note: The newsletter of C.H.E.A.R. is entitled "Hearing Research Developments", and is available from C.H.E.A.R., 871 McLean Avenue, Yonkers, New York, 10704. It reports the activities of the organization. One paid advertiser, the Widex Hearing Aid Co., advertises in this newsletter.)

Sept. 8-10

Southern Audiology Society Meets

The Southern Audiology Society held their annual convention September 8-10 at Ft. Walton Beach, Florida. The meeting fulfilled the Society's motto, "Conviviality and Erudition". Some 110 Society members participated in scientific meetings as well as the annual golf tournament, tennis tournament, deep-sea fishing venture and lethargic beach combing!

Research Grants Given for Ear Implants

The University of Washington Department of Otolaryngology has been awarded a \$1 million grant to study electrode implantation into the cochlea of monkeys. Dr. Joseph M. Miller will be project director. The grant is for a five-year investigation to determine the efficacy of such devices in monkeys. Dr. Miller reports that his team will study a four-channel model developed at the University of California, San

Francisco School of Medicine. Another study will be made at the University of Oregon Health Sciences Center, with Dr. Richard A. Wallach of the Otolaryngology Department as Project Director. Under this grant, cats instead of monkeys will be utilized; similar electrode implantation is contemplated. The studies are being funded by the National Institutes of Health and Deafness Research Foundation.

Robert Harrison was the overall chairman of the annual convention and John C. Cooper, from the University of Texas Medical School at San Antonio was chairman of the scientific sessions. John produced an exciting and interesting scientific program dealing with the general theme "Kids are Keen". Formal presentations were made by Jose M. Louro, Barbara Finlayson, Earl Harford, Richard Stream, and Katherine Stream. The outside guest

Yankee-cowboy speaker was Jerry L. Northern, University of Colorado Medical Center.

The Society's coveted annual rotating golf trophy was won for the year by Tom Davidson of Knoxville, Tennessee. The tennis tournament was won by Chuck Berlin, of New Orleans, Louisiana and the deep-sea fishing venture was completed with Wayne Staab of Minneapolis, Minnesota compiling the most caught fish.

At the Society's business meeting past President James Jerger, of Houston, Texas handed over the Southern Audiology Society presidential reins to Robert Harrison of the University of Mi-

Robert W. Hocks Named Chairman

The American Tinnitus Association has elected Robert W. Hocks as chairman of the association. Mr. Hocks is president of Hocks Laboratories in Portland and is active in many civic and national groups.

The A.T.A.'s goals are to support research into the problem of tinnitus and to educate the public about tinnitus.

Advisory Board Members are: Charles Unice, ATA's founder; David De Weese, chairman, Department of Otolaryngology, University of Oregon, Health Services Center; Albert Attyah, vice president of ATA; Del Clausen, U.S. House of Representatives; Bob McLennan, assemblyman, Californian legislature; Harold Wilkins, member of California State Board of Medical Examiners; Tony Habeeb, vice president, Metro Media Corp.; Kay Toma, California State Board of Medical Examiners; and Robert Hocks, president, Hocks Laboratories, Portland, Oregon.

A special Tinnitus Clinic has been started at the Kresge Hearing Research Laboratory at the University of Oregon. Only severe tinnitus patients are seen at this clinic.

The ATA held a public meeting on tinnitus in Portland on April 26, with 51 people attending. Further meetings are contemplated.

ami Medical Center. Full membership in the Southern Audiology Society requires residency in one of the confederate states as well as certification in audiology by the American Speech Hearing Association. However, associate membership is available to those who live in the northern aggression states but who share the Society's goals of conviviality and erudition. Applicants interested in membership should contact Bob Harrison.

Acoustic Horrors?

The following editorial appeared in the June, 1976 *Sounds & Vibration*, and deserves to be reprinted in its entirety:

THE 1/10 dB SYNDROME

"There are lies, damned lies, and statistics." Mark Twain said it almost 70 years ago. I wonder what he'd say today, particularly after reading some of the current publications and standards in acoustics.

It's difficult to take seriously the arguments which rage over whether "...it has been scientifically established that..." be Y or Y+2 dB; etc., etc. For level of noise which can be permitted in our work spaces whether the doubling rate should be Y or Y+2 dB; etc., etc. For indeed, very little has been scientifically established! In fact, we have only statistical inference, based upon some awfully shaky statistics.

Item: A distinguished audiologist recently wrote that three ostensibly qualified audiologists will take audiograms from the same patient with typically as much as 10 dB variance in results. What, then, is "normal" hearing acuity, and how do we define hearing loss?

Item: A distinguished audiologist recently wrote that three reports that the results of less than 10% (sic!) of all tests run at that lab are ever published. How would you like to base your statistical inference on 10% of the available data?

These are but a few of the horror stories which permeate the practice of acoustics. Differing measurement procedures, equipment variability, operator

Sam Lybarger, president of the Hearing Aid Foundation, announced that the Foundation has issued \$12,000 in grants to institutions serving the hearing impaired. He states that the Howard Fogel Memorial Fund was awarded to HEAR, Inc.

William A. Yost, Institute for the Advanced Study of Communication Processes, has been elected president of the Florida chapter of the Acoustical Society of America.

Norman Carmel and Frank Frueh were among the members of a group investigating the need for an organization of dispensing audiologists. The group is planning sessions at the American Speech and Hearing Association convention and at the Society of Medical Audiologists meetings to determine the need for such a national group, or whether it should

be an interest group within a larger organization.

Bob Briskey was a speaker at the Missouri Association of Licensed Hearing Aid Specialists at the Lake of the Ozarks in Central Missouri.

Wilbur L. Pronovost will be the new editor of *The Volta Review*, official journal of the A.G. Bell Assn. for the Deaf. Former editor George W. Felledorf will become active in demonstration projects, in teacher preparation centers, and in the new Ad Hoc Committee on Oral Advocacy.

Miriam Henoch, formerly Assistant Professor of Audiology at Ball State University, Muncie, Indiana, recently accepted a position as Associate Director of the Detroit Hearing and Speech Center, Detroit, Michigan.

Has the Pathology of Otitis Media Changed?

Dr. Imre Friedman, well known ear pathologist and author of *Pathology of the Ear* was a visitor to the United States recently. Following his attendance at the First International Conference on Cholesteatoma in Iowa City he furnished Corti's Organ with some remarks on the pathology of otitis media.

"It is important to realize that infections of the middle ear cleft have maintained their hold and that in spite of the excellent results of modern treatment of acute otitis media the incidence of both acute and chronic otitis media has not abated.

One is reminded of the lament of some otologists soon after the

introduction of penicillin in the treatment of acute otitis media and mastoiditis, regarding it "as a girlfriend who has jilted them; that she has been mixing with the wrong type of organisms and taking some drugs that have had an adverse effect on her character."

In other words it has been suggested that the pathology of otitis media may have changed, or that microorganisms causing it were different and that antibiotic treatment may have altered the disease.

The pathology of otitis media has not changed fundamentally as has been proven by the present writer's studies on human and ex-

perimental material when compared with earlier reports published in the pre-antibiotic period. Evidence has been presented that the old-fashioned organisms such as *S. pneumoniae* still cause extensive damage to human or animal ears and this has been confirmed recently by Howie.

The purpose of treatment is, of course, to alter the course of any disease. But the implication that it might have a masking effect and therefore to be harmful has been exaggerated.

Preventive medicine has an important role to play, but vaccination against pneumococcal otitis as advocated by Howie might be a dream of perfection."

Editorial

Several members have commented—some vehemently—about the apparent contradiction between the President's Message and our editorial in the July issue of the Organ. In his message, Dr. Ward indicated that in the future the society should directly enter into the realm of professional politics by working to abolish government controls and further licensing requirements. In our editorial we stated that the A.A.S. would NOT become involved in political issues or union type activities, nor would it engage in licensing activities. This philosophy is based on the statutes of the society which are the guiding principle of the organization.

Dr. Ward's message was not intended as a reflection of A.A.S. policy, but rather as a personal editorial comment from the President. He had suggested that the message be placed on the editorial page, as he considered it to be editorial in nature. It is therefore our fault for placing it as a feature item on the front page.

So unruddle your feathers, you reactionary members of A.A.S.! We will continue to be objective, non-controversial and simple in all matters!

Abstract of Papers at AAS Annual Meeting

The President's Message

Hearing Aids

"Relationship of Performance Characteristics in Hearing Aids to Cavity Volume."

Robert E. Jirsa and Thomas W. Norris [University of Nebraska Medical Center, Div. of Audiology & Speech Pathology, 42nd and Dewey Ave., Omaha, Nebraska 68105]

Hearing aid performance characteristics are traditionally measured in a 2 cc coupler to stimulate the impedance characteristics of the average real ear. Performance data thus obtained serve as the basis for hearing aid selection. While there are obvious differences between the coupler and real ear measurements (Lybarger, 1975), Walden and Kasten (1976) used adult ears to demonstrate that, at comfort setting, aided threshold improvement closely approximates acoustic gain. This same relationship between threshold improvement and acoustic gain for children, however, does not appear applicable. A 2 cc coupler simulation is perhaps appropriate for adults, but its appropriateness for children has not been established. While it is known that a reduction in cavity volume will increase SPL,

how a hearing aid's performance characteristics are affected by variations in cavity volume has not been systematically examined.

This present investigation was designed to examine: (1) specific changes in hearing aid performance characteristics resulting from a reduction in coupler volume from 2 cc, and (2) the relationship between aided threshold improvement in children and acoustic gain determined in variable volume couplers.

To examine the effect of volume reduction on acoustic performance characteristics, B&K analyses were completed on 24 hearing aids utilizing the traditional 2 cc coupler and experimental 1 cc and .5 cc couplers. As expected, reduction in cavity size was accompanied by systemic increases in both overall SPL and harmonic distortion. Specifically, as cavity size was reduced by one-half, SPL levels increased an average 6 dB. No significant changes were noted in frequency response.

To examine the relationship between threshold improvement and acoustic gain, aided and unaided SRT's and ear canal volume measurements were obtained from 8 hearing impaired children. Aided thresholds were established with the hearing aid to comfort level for a speech input of 60 dB SPL. Immediately following, acoustic gain was determined at comfort level in both the 2 cc coupler and the experimental coupler most closely approximating the subject's real ear volume. In all instances, threshold improvement exceeded the traditional 2 cc acoustic gain measure. When the acoustic gain was determined in a coupler approximating the real ear volume, a much closer relationship between acoustic gain and threshold improvement was obtained.

The results suggest that in small children where hearing aid selection is based largely on 2 cc specifications, care must be exercised that over-amplification does not occur. More accurate fittings may be obtained by determining real ear volume and measuring acoustic gain in a variable coupler whose volume approximates that of the real ear.

"The Effect of In-the-Ear Hearing Aid Canal Length on Frequency Response."

John C. Sinclair [H.C. Electronics, 250 Camino Alto, Mill Valley, California 94941]

Summary

This paper experimentally differentiates between two canal length parameters which affect the frequency response of in-the-ear aids. One is the volume of the cavity between the tympanic membrane and the hear-

ings are currently being held in Washington dealing with the possible economic impact of proposed federal regulations governing noise exposure—or more accurately, noise levels. That is, although the regulations are supposed to indicate limits of noise dose (some product of level and time), federal agencies seem unable to grasp this concept and persist in thinking that there is some sort of magic line dividing hazardous levels from non-hazardous ones. The concept of the critical level, alas, dies hard, and it apparently is not yet defunct. Indeed, it seems to have been tacitly accepted by the world's leading noise consultants.

But let me outline the background. In 1974, OSHA published the proposals in question, which, in essence, reaffirmed certain provisions of the 1970 OSHA regulations—a basic 90-dBA 8-hr permitted dose, with a 5-dBA per doubling time relation for shorter exposures to levels up to 115 dBA (15 minutes at that level), but with some changes and additions such as extending the 5-dB trading relation down to 85 dBA (i.e., 8 hr of 85 dBA would constitute a dose of 0.5), specifying that monitoring audiometry would be required for all workers whose daily dose is 0.5 or greater, and requiring regular noise surveys and resurveys. These steps were intended to increase the effectiveness of the program to ensure that hearing losses attributable to industrial noise are minimized.

However, it appeared that the program would be rather expensive to implement, especially if one tried to reduce all noise levels to 90 dBA rather than all exposures to the equivalent of 90 dBA for 8 hr. Damned expensive, in fact. The eminent noise engineering firm of Bolt, Beranek and Newman ("BBN", not "BB&N") estimated, at OSHA's request, that the cost to industry for reduction of all noise levels to 90 dBA (where it was possible at all) would be 13.5 billion dollars. In order to make that sum sound like chicken feed, OSHA also had BBN estimate what reduction to 85 dBA would cost; this estimate turned out to be 31.6 billion dollars, i.e. \$18.1 billion more than for reduction to 90 dBA. The ostensible reason for making an 85-dBA estimate was that the Environmental Protection Agency had been insisting that the Noise Control Act of 1972 (the Act that started all the mischief by stating that EPA was to determine those levels—not, unfortunately, doses—the attainment and maintenance of which were requisite to protect the public health and welfare with an adequate margin of safety) gave them the power to be involved in all decisions regarding noise, and they wanted 80 dBA as a maximum on all noise levels but would settle for 85 dBA.

Hearings on the original proposal took the better part of the summer of 1975, during which it developed, not too surprisingly, that industry opposed anything that would cost more money, and labor opposed anything except complete reduction of all even re-

motely hazardous noise levels by engineering means (so that the worker would not have to take any initiative whatever to protect himself). Each side smote the other hip and thigh, labor accusing industry of being insensitive and money-grubbing (quite ignoring the obvious fact that the costs of compliance will not come from the "capitalist stockholder" but from the ever-suffering consumer), and industry in turn pontificating that workers are sissy if they object to earplugs or earmuffs. In a flurry of bent statistics, bogus logic, fanciful speculation and eloquent non sequiturs, these hearings ended in just about a draw, I would judge.

However, apparently someone didn't like the figures of 13.5 and 31.6 billion dollars as the price of compliance, so BBN was commissioned by OSHA, for \$180,000 to get a better estimate of these costs. The revised figures, submitted to OSHA on April 21 and released to the public on June 18, are now only \$10.53 billion and \$18.5 billion. It is this report that is the object of the commentary that, one hopes, will surely be at a merciful end by the time you read this, although the final decision about the form of the new regulation by the Secretary of Labor will even more surely not be made public until after my daughter Laurie's 21st birthday (she happens to have been born on November 2).

When one reads, with any care at all, the BBN Report, it is obvious that these estimates represent the sheerest of speculation. From an estimate (very, very rough, to understate the case) of the exposure of some 62,000 workers in a variety of industries, plus knowledge of what BBN's services and recommendations have cost some of these industries, they generalize to the 13,000,000 workers of the present USA economy. Much of industry's attack on the report therefore takes the form of showing that in specific cases the new estimates are too low. (One of BBN's representatives blandly dismissed the relevance of such instances by declaring that the accuracy of the estimates for individual types of industry had nothing to do with the accuracy of the grand total—that any errors were bound to cancel out. This preposterous statement so nonplussed the audience that nobody had the presence of mind to point out that by that peculiar logic, there should have been no difference between the 1974 and 1976 cost figures, as they both involved rough estimates!)

The expected benefits of reduction to 85 dBA are, on the other hand, somewhat exaggerated in the report. The main benefit, of course, is that some number of workers who, without exposure regulation, would have suffered hearing impairment (under present convention, an average Hearing Level of 25 dB at 500, 1000 and 2000 Hz) will now not become impaired. However, BBN confused the issue by basing their estimates of rescued ears on two sets of industrial audiometric

data, one of which is known to be heavily contaminated by temporary threshold shifts, the other so scanty that its applicability is in question. If one rules out the former, then the estimate of the number of workers saved by the present 90-dBA regulation over a period of 20 years is about 260,000, but further reduction to 85 dBA will save only an additional 20,000 or so. Thus, although the cost per rescued ear is high enough in the 90-dBA system to give one pause, about \$40,000, it would be 10 times as high for those 20,000 benefitted by an 85-dBA limit: \$8 billion divided by 20,000 workers, or \$400,000 per impairment prevention—and the median degree of impairment of these 20,000 would have been less than 10% in the first place. Thus industry argues that even a 90-dBA regulation will result in serious financial problems, and an 85-dBA limit would mean economic disaster. The President's Council on Wage and Price Stability, I might add, agrees.

The BBN report estimates that an audiometric program to monitor the hearing of persons whose daily dose exceeds 0.5 will cost \$20 per year per worker, and that the required noise monitoring program will require about \$12/year/worker. They also estimate that if reduction of exposures were accomplished by use of personal protective devices alone (plugs, muffs), this could be done for about \$10/year/worker; since there are an estimated 4.5 million workers whose daily dose is 0.5 or greater, the total cost would be \$45 million per year. However, only short shrift is given to that figure, because the proposed regulation reaffirms formally the stance that the Department of Labor has taken on personal protection—namely that ear protectors represent only an interim solution, to be used only until the source of the noise can be brought down to 90 (or 85) dBA by "feasible" engineering controls. (This seems to be one of the few issues on which EPA is in agreement with OSHA.)

This issue—how protection is to be achieved—is the most controversial of all. Industry's view is that its duty to the worker includes only the identification of hazardous noise-exposure conditions, and then providing protection by the most feasible means, whether by noise reduction, rotation of work stations, or use of plugs and muffs. I happen to agree with this view, which is why I am representing several industries in this donkeybrook. The Department of Labor, however, excludes personal protective devices. In practice, this means that an industry must prove that reduction of a noise at the source is impossible if ear protection is to be deemed acceptable.

Furthermore, OSHA has taken the position that all possible noise-reduction steps must be taken even if it is known in advance that these steps still will

(Continued from Page 3)

ing aid, and the other the tubing coupling receiver out of the hearing aid. A hearing aid shell was built into an ear replica mounted on a Zwislocki coupler using a 1/2" microphone representing the tympanic membrane. The measured static volume of the Zwislocki coupler was .55cc. The "long" canal hearing aids reached the outside edge of the Zwislocki coupler volume. The "short" canal used in the experiments increased cavity volume by .43cc. By using combinations of long canals and long receiver tubings with short canals and short receiving tubings, it was possible to differentiate the two effects mentioned above. The experiment was repeated using real ear techniques, as compared with the ear replica measurements and very good agreement observed. In particular there was a 10 dB increase in sound pressure level to the ear drum at frequencies below 500 Hz when using long canals and long tubings.

"Increasing Acoustical Efficiency with In-the-Ear Hearing Aid Fittings."

T.S. Griffing and D.A. Preves [Starkey Laboratories, Inc., 6700 Washington Ave. South, Eden Prairie, Minnesota 55343]

Response curve data of gain provided by head diffraction, pinna focus and external meatus resonance was obtained in an anechoic chamber using a probe microphone on real ears and on Knowles Electronics Manikin for Acoustical Research (KEMAR). This datum was comparable to that obtained in an earlier study (F.M. Wiener and D.A. Ross, J. Acoust. Soc. Am. 18; pp 401-408 - 1946) which showed that the natural physiology of the head significantly preamplifies incident acoustic sounds.

Further measurements were made comparing response curves obtained for in-the-ear and both bottom facing and forward facing behind-the-ear microphone inlet positions. Results showed, as in a previous study, (O. Berland and T.E. Nielsen), Oticon Laboratories, Denmark - Oct. 1968) that an in-the-ear microphone inlet location provides 5-10 dB more gain in the 1500 to 5000Hz region than the better of the two behind-the-ear microphone locations. Almost all of the preamplification remains after occluding the concha and external meatus portions of the ear with the earmold of an in-the-ear aid. Thus, the acoustic gain provided to incident sound by an in-the-ear microphone inlet does not appear to be a function of external meatus resonance acting in conjunction with an unfilled concha. The Oticon study reached the same conclusion because a skeleton earmold was in place during all of their probe mic tests. Significant size vents in the in-the-ear aids add further gain due to the 2.5KHz canal resonance combining with the microphone inlet preamplification.

As a result of this increase in

acoustic gain, before the hearing aid is even turned on, signal to noise ratio is enhanced in the 1500 to 5000Hz frequency region. The amount of energy contained in this frequency range is critical to achieving good discrimination in the presence of noise (S.J. Freedman, Laboratory for Research in Neuropsychology, Inc. - May 1970).

Localization is achieved, in part, by utilizing differences in the spectrum of incident sound from various directions (J. Blauert, *Acustica*, 22; 1960-70). It is therefore desirable to have these differences magnified to the largest extent. Thus, also as a result of the increased high frequency gain provided by an in-the-ear microphone inlet and vented earmold, an improvement in localization may be obtained with an in-the-ear hearing instrument.

Peripheral Auditory & Vestibular Systems

"Estimation of the Stapedius Reflex in Industrial Hearing Loss"

P.W. Alberti F.R.C.S. [Mount Siani Hospital, Div. of Otolaryngology, 600 University Ave., Toronto, Ontario M5G 1X5]

The current epidemic of noise-induced hearing loss is stretching resources of hearing testing facilities to the limit. In the Province of Ontario, Canada, with its population of 8 million people we anticipate in excess of 2,000 new compensation claims for hearing loss in the year of 1976. In order to maximize the use of limited major testing facilities an attempt is being made to develop a profile of test results based on relatively simple testing procedures which would indicate reliable or unreliable audiograms. This profile will help select people requiring 'advanced' testing. One of the parameters being investigated is the value of stapedius reflex estimations.

In the past 5 years some 1,500 patients with occupational hearing loss have been tested for compensation purposes in our Department. Virtually all of them have had stapedius reflex thresholds measured for pure tones, and large numbers also for white noise, and some for high and low pass filtered white noise. An analysis has been made of the relationship between stapedius reflex thresholds to pure tones, and the pure tone threshold, and also the results of the Neimeyer test in the population, and a statistical evaluation made of its efficacy in predicting exaggerated hearing loss (or unreliable hearing threshold) based upon the results of evoked response audiometry plus a full conventional test battery.

We feel it is a useful tool as a part of a battery of tests in identifying the patient who requires testing in a central facility with sophisticated equipment, including ERA audiometry.

"The Effect of Ventilation on Middle Ear Volume and Eustachian Tube Function in Secretory Otitis Media."

H. Bryan Neel, III, Lawrence W. Keating and Thomas J. McDonald [Mayo Clinic and Mayo Foundation, Rochester, Minnesota 55901]

Conductive hearing loss due to secretory otitis media is the commonest form of hearing loss in children. Eustachian tube dysfunction is often implicated as the most important factor in the origin and course of the disease. It is well known that myringotomy, aspiration of fluid from within the middle ear, and ventilation with any one of several types of tubes will restore hearing and mobility of the tympanic membrane in the vast majority of patients. The effects of these procedures on eustachian tube function and middle ear cleft volume, particularly on a long-term basis, has not yet been clearly delineated.

Thirty-six children (72 ears) with secretory otitis media were studied. During the course of the disease fluid was aspirated from the middle ear and silastic ventilation tubes were inserted. Hearing levels, tympanogram type, middle ear volume and eustachian tube function were determined pre- and postoperatively.

Following myringotomy, aspiration of fluid, and ventilation we found that 1) middle ear volume progressively increased during a period of three to eight months postoperatively, 2) eustachian tube function remained abnormal while ventilation tubes were in situ, and 3) hearing was restored to normal levels. The significance of these results will be discussed.

"Air Calorics: A Technique and Results."

Jaime T. Benitez, Kenneth R. Bouchard and Yong K. Choe [William Beaumont Hospital, Div. of Otolaryngology, Royal Oak, Michigan 48072]

The bithermal caloric test with water has been an important tool for the evaluation of vestibular function. Performing the test with air has many advantages. Some problems have been noted: patient discomfort due to the acoustic component of the air flow, a burning sensation, ear ache and increased variability of caloric responses. It is felt that a major problem is one of technique.

A short film was presented describing a method that greatly diminishes the above noted difficulties. To insure appropriate air presentation, a delivery probe was designed (fig. 1). This modification has allowed a flow that provides adequate vestibular stimulation yet not annoy the patient. It permits one to easily keep probe placement consistent from ear to ear and fit different external canals.

The film illustrated techniques that allow accurate and repeatable stimulation with air; appropriate head placement, examiner's position, visualization of flow rate and/or temperature variations during stimulation. Due to the difference in heat capacity between air and water, each point of possible variability is magnified for air. Constant technique is essential.

We are able to use a flow of six liters/min for 60 seconds at temperature settings of 24° and 50° C. It is essential that the temperature is controlled close to, but not within the external canal. The temperature in the canal is affected by the body temperature and by the amount of back-flow. As measured by a sensor at the tip of the probe, one can see the temperature course during irrigation in the recording (fig. 2). An examination of these curves for hundreds of stimulations have shown a marked similarity between ears.

A normal study was carried out (30 subjects). The range of caloric responses, mean maximum speed, and standard deviation are similar to water stimulations. Various tests of significance performed show no differences between ears for warm or cold (p. 50). The surprising finding was that there was no significant difference between all four irrigations. Jongkee's formulae, using the clinically accepted two times the standard deviation disclosed a 16% value for unilateral diminution and 12.5% for directional preponderance.

We have performed over 2000 clinical examinations that incorporate the technique with satisfactory results and minimal patient discomfort. These findings were discussed.

Natural History of Idiopathic Sudden Hearing Loss."

F. Blair Simmons and Douglas Mattox [Stanford Univ. Medical Center, Div. of Otolaryngology, Stanford, California 94305]

We have reviewed the circumstances, treatment, audiometric and other parameters associated with Sudden Hearing Loss (SHL) in a prospective study of approximately 100 patients. All were primary cases, not second-order referrals. Prognosis for recovery is excellent and is best correlated with early diagnosis, but is completely independent of type of treatment. Typical audiometric findings, vertigo, demographic, and laboratory findings will be reviewed.

"N2 Latency of the Human Whole-Nerve Response to Filtered Clicks"

S. Zerlin and R.F. Naunton [University of Chicago, Section of Otolaryngology, 950 East Street, Chicago, Illinois 60637]

In previous studies, we described the physical and audiometric characteristics of filtered (tave) clicks (S. Zerlin and Naunton, *Audiology* 14:13 - 1975) and began exploring ear's electrical response to clicks (R.F. Naunton and Zerlin, *Audiology* 15: 1-9, 1976) the course of electrophysiologically assessing the hearing children seen in our laboratory. We have obtained results on young ears with normal peripheral sensitivity and can now describe normal N1 latency function of both frequency and sensation level. In Figure 1, mean N1 latency is plotted in semi-log coordinates as a function of sensation level with frequency as parameter. Latency varies monotonically (essentially linearly) with sensation level at all frequencies, and each frequency function is displaced upward as frequency decreases. These results follow from what is known about traveling-wave behavior in the cochlea, and are confirmed by single unit recordings in cat, i.e. the human nerve response to narrow band click appears to be a valid

[Continued on page 7]

THE INTERROGATORY

Question: When do you deem it advisable to initiate a myringotomy with tube placement? Do you have any particular rationale for this policy?

Charles D. Bluestone
Children's Hospital of Pittsburgh

At present, our indications at

Children's Hospital of Pittsburgh for tympanostomy tube insertion are the following:

1. Persistent middle ear effusion present for two months or longer and unresponsive to adequate medical treatment:

The patient must have been treated with ampicillin and, pre-

ferably, an oral decongestant-antihistamine for at least two weeks. If the patient is allergic to ampicillin, then erythromycin and a sulfonamide should be administered. This mode of therapy is strictly empirical since there has been no controlled study for chronic middle ear effusions re-

ported in the literature.

2. Recurrent acute otitis media, at least three bouts during the preceding three months:

Again, this indication has not been absolutely proven in a controlled clinical trial. The rationale for this procedure is the elimination of persistent or transient negative middle ear pressure which prevents aspiration of unwanted nasopharyngeal secretions into the middle ear. In addition, it is our clinical experience that when patients have had bilateral tympanostomy tubes inserted for this indication, they remain free of symptoms except for occasional intermittent otorrhea. In addition, we have noted that when one tube spontaneously extrudes and the other tube remains in place, it is a frequent finding that when the patient develops an upper respiratory infection, the middle ear that does not have a tympanostomy tube becomes infected, while the ear that has the tympanostomy tube remains normal. For these reasons, we feel that tympanostomy tubes are efficacious, especially in the very young.

3. Persistent tympanic membrane retraction pockets with impending acquired cholesteatoma:

We frequently use a tympanostomy tube to restore middle ear ventilation when there is a deep retraction pocket in the posterosuperior quadrant in the presence of high negative middle ear pressure. The tube relieves the middle ear atelectasis and the tympanic membrane frequently will return to the neutral position. If the retraction pocket does not return to normal the patient has adhesive otitis media and impending cholesteatoma. It is our observation that the chain of events in acquired cholesteatoma is the following: persistent negative middle ear pressure, atelectasis, posterosuperior retraction pocket, adhesive otitis media, and finally, cholesteatoma.

4. Persistent negative middle ear pressure with significant hearing loss:

Many patients are seen in our Outpatient Department with persistent significant hearing loss and sustained high negative middle ear pressure proven by tympanometry and by pneumatic otoscopy. If this condition is not relieved by medical means, a tympanostomy tube should be inserted to eliminate the hearing loss. Negative pressure may cause just as much hearing loss as a middle ear effusion and if persistent, will most likely cause a handicap.

The complications of tympanostomy tubes still present a problem. Troublesome otorrhea, persistent perforation, and implantation cholesteatoma. Reflux of nasopharyngeal secretions or from contamination from the external canal during bathing or swimming may be eliminated by the advent of the new semipermeable membrane ventilating tube. This tube should prevent contamination from water from the external canal and prevent reflux from the nasopharynx.

Raymond P. Wood II
University of Colorado Medical Center

There are two indications for myringotomy and ventilating tube placement in children with chronic serous otitis (one must first rule out other lesions such as nasopharyngeal carcinoma, angiofibroma and submucous cleft palate and cleft palate). These indications are: first, significant hearing loss, which I feel may be defined arbitrarily as 20 dB or greater in the speech frequencies. In some instances such as evidence of speech problems or poor performance in school or a superimposed sensorineural hearing loss, a lesser degree of conductive loss may be considered significant. The second indication is marked atelectasis with retraction of the tympanic membrane and impending adhesive otitis media, regardless of the degree of hearing loss. In the infant, if we can be relatively certain of the hearing being normal, no treatment is indicated. If the hearing is felt to be impaired, the presence of fluid and an immobile tympanic membrane may constitute an indication for myringotomy.

In general, we perform adenoidectomy and myringotomy and tube placement at the same procedure. If the patient has submucous cleft palate, we may perform no adenoidectomy or only lateral band adenoidectomy. Children with cleft palate and middle ear effusion should have myringotomies and grommet tubes placed at the first sign of effusion.

It is demonstrable that the hearing loss can usually be returned to normal levels by myringotomy and tube placement. Furthermore, it can be documented that delayed or impaired speech and language development occurs in otherwise normal children whose hearing loss exceeds 20 dB. Thus, the indication of hearing loss.

The long-term consequences of adhesive otitis media and/or frequent inability to repair these tympanic membranes and reconstruct the ossicular chain with good results, seems to me to argue strongly for the use of the relatively simple procedure of myringotomy and tubes. I cannot, however document our success from this approach.

The role of medical therapy in middle ear effusion is not well established. There is no documented proof that decongestants are of benefit, although we use them. The use of intranasal steroid sprays is an intriguing possibility in certain cases where allergy may play a role in the etiology. Antibiotics have no indications and in fact if one reviews the bacteriological studies of middle ear effusions, the carefully done studies fail to demonstrate the presence of bacteria either by culture or by the indirect evidence of bacterial infection, which is suggested by the absence of polymorphonuclear leukocytes.

Meeting of the Executive Committee of the AAS

DATE: October 4, 1976

PLACE: Hilton Convention Center
Las Vegas, Nevada

TIME: 8:30 AM

MEMBERS IN ATTENDANCE:

Jaime T. Benitez
David Dolowitz
Bruce Graham
Norma T. Hopkinson
Fred Linthicum
Geary McCandless
Ralph Naunton
Ross Roeser
Hiroshi Shimizu
F. Blair Simmons
W. Dixon Ward
Laura Ann Wilbur
Aram Glorig
J. Donald Harris

GUESTS:

Marion P. Downs
Gae O. Decker
Wolf Niemeyer

The meeting was called to order by President Ward at 8:40 AM.

1. The minutes from the 1976 Executive Committee Meeting were read and approved.

2. The income and expense statement for the period January through August was read and approved.

3. After a brief discussion, the following motion was made:

"The editor of Corti's Organ be automatically appointed as an ex-officio member of the Executive Committee." (Passed unanimously).

4. The Statutes were reviewed with respect to membership. In the statutes, it is stated that the Executive Committee must approve all new members. Since this procedure has not been formally followed, the following motion was made:

"All members who have been informally admitted to the Society shall be approved for membership by the Executive Committee." (Passed unanimously)

In the future, applicants will be given provisional membership until they are formally approved by the Executive Committee during the Annual Meeting.

5. A discussion regarding how to attract new members was held. After discussing several possible mechanisms the following motion was made:

"The membership Sub-Committee consider problems of recruiting members, ensuring professional distribution of membership, and maintaining the size of the present membership." (passed unanimously)

Ralph Naunton will report on these activities at the next Executive Committee Meeting.

6. During the last meeting of the Executive Committee, the following motion was adopted:

"The Executive Committee authorizes the President of the American Audiology Society to approach the International Audiology Society requesting that the American Audiology Society be made the recognized representative to the International Audiology Society from the United States."

Because this statement implies sole representation, the following motion was made:

"The phrase, 'the recognized representative' be changed to 'a recognized representative.'" (Passed)

7. President Ward indicated that the International Commission on the Biological Effects of Noise (ICBEN) has requested that the Society provide nominal sponsorship at the next International Congress on Noise as a Public Health Problem. After discussion, the following motion was made:

"The American Audiology Society will provide non-financial support for sponsorship of the next International Congress on Noise as a Public Health Problem." (Passed).

8. The possibility of having an independent convention was discussed. The consensus was that the size of the membership of the Society is not adequate to sponsor an independent meeting. It was decided to hold our next meeting with the Fall Meeting of the acoustical Society of America if it is to be held in Miami, Florida. Harris Pomerantz was appointed Program Chairman.

9. Several instances in which the Society's name was used inappropriately were cited. The appropriateness of having the term "Audiology" as part of the Society's name was questioned, since all members are not audiologists according to the contemporary restricted use of the term in the U.S. A. The following motion was made:

"The proper procedure be instituted for changing the statutes of the American Audiology Society, including changing the name of the society to the American Auditory Society, and that a committee be formed to make additional proposed changes in the statutes." (Defeated)

After the defeat of this motion, an alternate motion was made as follows:

"Membership of the American Audiology Society be apprised of the possibility of a name change

for the Society through Corti's Organ and be asked for their reaction." (Passed)

The Executive Committee will approve the material to be printed in Corti's Organ before it is published.

In addition, because there are several areas that are not specifically clear in the statutes, the following motion was made:

"The President of the American Audiology Society appoint a committee to review the statutes and suggest possible changes." (Passed)

10. The Editorial Policy Board must reappoint its members every two years. The following motion was made:

"The present members of the Editorial Board be retained and two additional members be appointed by the Editor-in-Chief." (Passed)

11. Volume 1 of the Journal of the American Audiology Society did not utilize the allotment of 360 pages. It was decided that the Secretary/Treasurer either contact Williams & Wilkins directly or have an Executive Committee Member contact them directly to propose that the unused pages be allocated to future volumes.

12. F. Blair Simmons was elected Vice President/President Elect for 1977.

13. A Committee was appointed to establish guidelines and criteria for the Carhart Memorial Lectureship and Award, and to identify the recipient of the next award. Tom Tillman was suggested as Chairman of the Committee, with two alternates, Leo Doerfler and Wayne Olsen. President Ward will contact Dr. Tillman regarding this.

14. A Nominating Committee was formed to select names for replacing the seven Executive Committee Members to be replaced next year. Dave Dolowitz was appointed Chairman, Laura Wilbur and Hiroshi Shimizu were appointed members.

15. Several other organizations refrain from using degrees when referring to their members. As we have no set policy on this, the following motion was made:

"The American Audiology Society refrain from listing degrees of its members in the Directory and in Corti's Organ, but degrees shall be indicated in the Journal of the American Audiology Society." (Passed)

There being no additional business, the meeting was adjourned at 11:45 a.m.—R.J. Roeser.

The Interrogatory

(Continued from Page 5)

David F. Austin
Chicago, Illinois

In the treatment of otitis media with effusion, the use of myringotomy with tube insertion is so wide spread as to be considered standard. At the same time it is well documented that approximately 95% of such patients will recover spontaneously leaving a small group with a more chronic, difficult to treat problem. The efficacy of tube insertion for this group has not yet been fully documented.

It has been demonstrated on the other hand that in bilateral cases, if one ear is untreated and tube insertion carried out in the other, both ears respond identically; clearing in most and a few continuing with effusion. The implication of this finding is that either some other aspect of the surgical procedure than the tube insertion is therapeutic (the induction or detubation, the nitrous oxide administered, the adenoidectomy) or that the pre- and post-operative care is effective in securing resolution.

My standard treatment for such patients is to treat medically nose and throat infection, improve the nutritional status, administer vitamin C in 1 gram daily dosage to children (2 grams to adults) and to teach self-inflation of the ear via the Frenzel technic. Non-resolution of the problem after four weeks indicates adenoidectomy. At this time if hearing loss is present, a myringotomy with aspiration is performed on one ear only. No tube insertion is done. Post-operative care is carried out as defined for the pre-operative period.

Fewer than one percent of my younger patients have failed to respond to this method of treatment. Only 4 adult patients have had needed tube insertion in the past five years. I feel that the children with chronic unrelenting otitis with effusion (such as those with cleft palate problems) should be fitted with a hearing aid rather than have multiple tube insertion.

Michael M. Paparella
University of Minnesota

I would consider myringotomy and ventilation tubal placement only for chronic middle ear effusion, that is, chronic serous otitis media or chronic mucoid otitis media. It should not be used in acute or subacute cases since these should be treated conservatively. Usually youngsters with conductive losses are picked up through screening programs in the schools and by the time we see them they have already had longstanding cases of chronic middle ear effusion. Nevertheless, conservative therapy using medication and eustachian tubal exercises is still useful. In general, if the fluid has persisted after several months of medical management I would utilize tubal placement.

Another indication for tubal placement is in children who have recurrent bouts of acute suppurative otitis media. We

have seen children who have them so frequently as to occur every two weeks or so. In these instances we treat the child actively with medication, including appropriate antibiotics and when the child's ear is as devoid of infection as possible, then, under sterile conditions, a myringotomy and tubal placement are done. The purpose here is to prevent further attacks of acute suppurative otitis media and in small children it is remarkable how beneficial this can be if utilized properly.

There is a third indication which may not be germane to this particular discussion, namely, the use of ventilation tubes in conjunction with tympanoplasty techniques. The paramount underlying problem that leads to chronic otitis media continues to be eustachian tubal ventilation dysfunction. As such, whenever possible, a ventilation tube is inserted through a normal portion of tympanic membrane when grafting and reconstruction takes place during tympanoplasty in order to assist the eustachian tube in its function of ventilating the round window.

Victor Goodhill
Beverly Hills, California

Our indications for myringotomy with tube placement relate to persistent middle ear fluid retention refractory to appropriate medical therapy. This includes cases with and without evidence of mastoid haziness on x-ray, and it includes patients who have re-accumulations of fluid on adequate medical therapy. Rationale is based upon the fact that many patients will respond to medical therapy which frequently will include allergic management of concomitant nasal and sinus disease. In our techniques we emphasize both anterior and posterior inferior radial incisions for adequate suction and ventilation, even though only one tube may be placed. My colleagues and I use varying types of tubes for special purposes.

This represents the opinion of Victor Goodhill, Seymour J. Brockman, Irwin Harris, Joel Shulman, and Stephen Cooper.

F.H. Linthicum, Jr.
Los Angeles, California

Myringotomy with tube placement should be done after a complete attempt to control the situation with medical therapy. Most children develop middle ear effusions with respiratory infections, and it sometimes takes three weeks for this to resolve if no treatment is given. Therefore, one examination is not enough to determine whether myringotomy and tube placement should be done, particularly if the child has had a history of a respiratory infection within the preceding three weeks. A careful history of the possibility of an allergic diathesis, either in the child or the parents, should be obtained. Should there be any indication of such,

then an antihistamine usually in conjunction with a decongestant is given at least a three-week trial. Should this fail to result in a resolution of the fluid in three weeks, then the child is taught to Valsalva or the parents to politzerize the child twice daily 30 minutes after the administration of the antihistamine and decongestant. For the politzerization I use the rubber nipple, developed by Victor Goodhill and supplied by the Surgical Mechanical Research Company, that fits on the end of a teardrop-shaped rubber syringe, which can be obtained at any drugstore.

Should conservative treatment fail to produce resolution of the fluid and if there is a significant hearing loss or recurrent acute otitis media due to infection of the middle ear effusion, then myringotomy and ventilation tube placement is indicated. For the first placement of ventilation tubes I prefer the collar-button-type tube, placed anterior to the umbo with the flange impinged under the umbo (Fig. 1). These will usually remain in place up to a year. Once the extrusion has taken place, the above-mentioned medical therapy is again carried out, and if there is no recurrence of the fluid after extrusion, the child is seen three weeks after his next respiratory infection and again medical and autoinflation treatments are begun.

Semipermanent tubes are used if there is evidence of damage to the tympanic membrane or temporary tubes have been previously inserted. These are called mesh tubes and are similar to the Per-Lee tube. They have the advantage over the temporary tubes in that the flange is soft and can be inserted through the myringotomy incision smaller than the diameter of the flange. The flange is placed medial to the handle of the malleus (Fig. 2). The tubes are left in place until the child has reached an age that one can be fairly certain that the eustachian tube has matured. This is tested utilizing the vacuum pump of the tympanometry equipment. If the patient can relieve negative pressure within ten swallows, then it is considered time to remove the tube. In a young child or adolescent, this usually requires a general or local anesthetic for removal.

RATIONALE

Patience on the part of the doctor and the parents will usually allow one to clear middle ear effusions with conservative medical treatment. However, persistent significant hearing loss, recurrent acute otitis media, or evidence of impending permanent damage to the tympanic membrane, particularly in the pars flaccida, are indications for middle ear ventilation. The only semiurgent situation is that of the idiopathic hemotympanum, or blue eardrum. This indicates a development of a cholesterol granuloma which may within a year or two become organized by fibrous tissue and create the completely fibrotic middle ear, for which there has been found no suitable tympanoplastic correction.

Virgil M. Howie
Huntsville, Alabama
[Dr. Howie submits his article, "Treatment of Serous Otitis Media with Ventilatory Tubes," Clinical Pediatrics, 13-11, Nov. 1974. Excerpts from this article follow:]

We report here the results of audiograms on ten children in a private pediatric practice who had 19 tympanostomy tubes inserted under local anesthesia during a one-month period. All children were diagnosed as having serous otitis media prior to insertion of the tympanostomy tubes; two had a superimposed purulent otitis media in one ear and serous otitis media in the other year.

PATIENTS

The ten children, ranging in age from four to nine years, were seen in a one-month period in the general practice of pediatrics of the two authors. In each child, pneumatic otoscopy indicated the presence of middle-ear fluid which was known to be persistent for at least one month or had recurred at least three times during the preceding 12 months. Of the 17 cultures performed, only two showed the usual pathogens (pneumococcus and Hemophilus influenzae) associated with otitis media; these two middle ears seemed acutely inflamed prior to insertion of the tympanostomy tubes.

RESULTS

The results of the audiograms performed before, immediately after, and two to three weeks after effective middle-ear ventilation shows the mean improvement in hearing to be 15.3 decibels. All 10 patients could hear all

frequencies at 20 decibels or less immediately postoperatively. The two-week audiogram showed even better hearing than the 15-minute postoperative audiogram.

COMMENTS

Children under four years of age have otitis media much more frequently than the 10 children aged four to nine years who are described in this study. However, the testing of hearing is more complex and less reliable in the younger children. Middle-ear fluid can be persistent or recur immediately with or without infection.

Several studies have shown that suboptimal hearing even when intermittent may permanently affect a child's ultimate verbal intelligence. A high rate of conductive hearing impairment exists among the retarded. Some of this retardation may be caused by less than optimal hearing.

Our observations, made in a one-month period in a two-man partnership general pediatric practice, leave no doubt that tympanostomy tubes can and do improve hearing instantly and that this improvement continues with functioning ventilatory tubes. Richards, who compared simple myringotomy with the insertion of grommets, noted that the ears receiving grommets had less hearing loss as long as the grommets remained functional and in place.

Middle-ear fluid can best be detected by the use of the Impedance Audiometer ("jet see style") but can also be detected by the routine use of the pneumatic otoscope ("horse and buggy style"), which is available to every practicing primary physician. Primary care physicians should be skilled enough to recognize and treat this problem as an office procedure, since recurrent otitis media affects 20 percent of the babies under our care.

LaVonne Bergstrom
University of California at Los Angeles

The placement of a myringotomy tube is a somewhat individualized decision. I would be inclined to do it quite promptly in the cleft palate child who very likely is not going to resolve serous otitis media promptly. In the youngster or adult whose onset is clearly related to a recent upper respiratory infection and/or a change in atmospheric pressure, I may not treat it at all but just wait to see if it resolves. If an acute episode is particularly bothersome to the individual, particularly the adult, or is slow to resolve, I would use myringotomy to aspirate the fluid but would not place a tube. In the individual, usually a child, who has a prolonged problem that does not resolve readily and who has already been treated with decongestants, I would approach the problem in one of two ways. If his adenoids are hypertrophied and seem quite clearly to be contributing to the problem I would do adenoidectomy and perhaps

[Continued on Page 7]

AAS Annual Meeting . . .

[Continued from Page 1]

of the SSI in various types of evaluations: 8th nerve lesion, Central problems, Brain Stem Trauma, Basilar Artery Insufficiency, and Presbycusis. One measure of importance is the difference between the SSI Max and th PB Max; i.e., the point on the articulation curve at which the SSI scores fall off, as compared with the PB scores fall-off. For example, if the relationship differs out of proportion to the degree or shape of the audiogram, an 8th nerve lesion is suspected. If the SSI function falls below that of the PB, and the audiogram is not worse in the low frequencies, a central loss is suspected.

In presbycusis the SSI Max is 20-25 dB lower than PB's, and the scores may differ markedly: 70%

for PB's, 40% for SSI's.

These results indicate that the scope of speech audiometry can be expanded to diagnostics. In addition, SSI's can be used in hearing aid evaluation to measure performance with and without the hearing aid. If one tests at 60 dB SPL the competing message can be varied to arrive at some significant differences.

Following the lecture, A.A.S. President Dixon Ward presented Jerger with a plaque memorializing the occasion of the 1st Carhart Memorial Lecture. An honorarium was also presented.

The contributed papers that followed were well received by the membership. Abstracts of all these papers are published in this issue.

The Interrogatory

[Continued from Page 6]

myringotomy and tube under the same anesthetic. If his adenoids have been removed and removal has been adequate and the problem has persisted I would perform myringotomy and place a Grommet tube. In the adult who develops serous otitis media without any apparent cause such as recent upper respiratory infection or abrupt change in altitude I would make a careful search for a nasopharyngeal tumor. This would also be true of the young boy or adolescent male who develops serous otitis in conjunction with obstruction of nasal breathing which he has not previously had. In this instance I would be suspicious of a nasopharyngeal angiofibroma. The treatment in this instance would be directed at the primary cause and not at secondary symptoms.

There is no scientific evidence that decongestants work and therefore it is difficult to rationalize the use of this type of medication on any scientific grounds at all. I think we need to recognize this fact whenever we prescribe these medicines. Most of us have used oral decongestants for acute episodes of nasal congestion and have noted what seems to be symptomatic improvement. Since the mucosa of the Eustachian tube is identical to that of the nose, it seems rational that this method should work but, to be honest, we have no proof of this. My rationale for doing myringotomies and tubes promptly in the cleft palate child is that probably close to 100% of young cleft palate children have serous otitis media and about 50% of those with submucous cleft palate have this or another manifestation of chronic middle

ear problems. Adenoidectomy is often contraindicated in children with overt cleft palates, repaired or unrepaired, and decongestants don't work in this particular situation which seems to be on the basis of mechanical malfunction of the Eustachian tube musculature. There is perhaps some evidence that chronic negative pressure and perhaps chronic serous effusion in the middle ear may be permanently damaging. There is no question that the hearing loss involved when chronic or frequent may interfere with the child's learning processes. Therefore, in these children I feel there is no place for temporization. In other instances, I would not perform surgery immediately. An example of this would be the child who wishes to swim during the summer vacation from school and who has no indication that permanent changes are beginning to occur in the ear such as retraction or monomeric membrane. I would let this child swim with the fluid in the middle ear

and then, prior to school, if the condition is still present, I would do a myringotomy and insert tubes. I might add that there are occasions in the adult who has chronic middle ear effusion who has had a tympanoplasty to close a large perforation there may be indication for doing a myringotomy and placing a tube to ventilate the middle ear and allow him to have a small opening in the tympanic membrane rather than a large one. Again, I would like to emphasize that there has been no good objective double blind study of the efficacy of any of these modalities and I think that the construction of such a study will prove difficult.

JOBS, JOBS, JOBS

No, we don't have any available, but we'd like to list yours. Need a Friendly Otolaryngologist in your medical group, or a competent Audiologist in your practice, hospital or clinic? Send in your job requirements and the old ORGAN will try to get you a body.

Abstract . . .

[Continued from page 4]

cation of "place" on the basilar membrane.

These data serve additionally, as norms for diagnostic electrocochleography: ambiguous N1 responses can be assigned a greater or lesser degree of validity depending upon their correspondence to these mean values.

Figure 1: N1 latency of the human whole-nerve response as a function of (third-octave) click frequency and sensation level. Mean results based on promontory recordings of 15-20 normal young ears.

Central Auditory System

"Effect of Peripheral Hearing Loss on Central Auditory Tests". Gerald E. Miltenberger, Gerald J. Dawson and Anthony N. Raica [Center for Audiology & Speech Pathology, University of Texas Medical Branch, Galveston, Texas 77550]

This study was conducted to assess the feasibility of administering a central auditory test battery to patients with sensorineural hearing losses. Seventy subjects with sensorineural hearing losses of varying severities and slopes participated in this study. The subjects ranged in ages from 14 years to 65 years. In addition to receiving a standard audiological assessment and otological examination, each subject also received a central auditory processing (CAP) test battery consisting of: Task 1 - a dichotic listening task consisting of competing sentences having similar length and linguistic content; Task 2 - monosyllabic filtered words passed through an electronic filter. The rejection characteristic was 18dB/octave for those frequencies above 5kHz; Task 3 - a binaural fusion task utilizing spondaic words with the presentation of a low-band-pass segment (500-700 Hz) to one ear while the other ear is simultaneously presented with a high-band-pass segment (1900 - 2100 Hz) of the same word; and Task 4 - a rapidly alternating speech task involving single sentences wherein the continuous stimulus is switched alternately between the two ears every 300 msec. The CAP test battery was administered to assess the following: (1) the effect of degree/configuration of hearing loss on these tests, and (2) the effect of reduced speech discrimination ability on these tests.

The results of the data showed that patients with sensorineural hearing losses of different severity and slopes produced poorer scores during the administering of the filtered speech task than any of the other three subtasks. Scores obtained during the administering of the filtered speech subtask were affected by (1) degree of hearing loss at 2000 Hz when the puretone air conduction thresholds at 500 Hz and 1000 Hz was within normal limits, (3) the PB max scores, and (4) the overall degree of hearing loss

through the speech frequencies.

The other subtasks: competing sentences, binaural fusion, and alternating speech were not effected to the same extent or necessarily in the same manner as the filtered speech subtask.

In summary, the described central auditory test battery can be utilized on patients with sensorineural hearing losses providing all results obtained are interpreted with caution in view of results obtained during the standard audiological assessment.

"Rapidly Alternating Speech Perception: A Test of Brain Stem Dysfunction." George E. Lynn and John Gilroy [Wayne State University School of Medicine, Department of Neurology, Detroit, Michigan 48201]

The identification of auditory disorder originating from brain stem lesions remains a major clinical problem in neuro-audiology. The purpose of this paper is to describe a modification of Bocca's and Calero's "swinging speech technique" called Rapidly Alternating Speech Perception (RASP) and its localizing value in identifying patients with brain stem disorders.

The test consists of recorded sentences which, when spoken, alternate rapidly between the listeners two ears in 300 msec bursts. In the normal listener with intact central auditory pathways, the amount of information presented to each ear alone in these 300 msec bursts is insufficient for understanding and discrimination scores are usually less than 10% correct in each ear. However, when the material is presented binaurally the alternating bursts of speech fuse or resynthesize into meaningful sentences with high intelligibility (90 to 100% correct).

Sixty-seven patients were tested with RASP. Performance scores in the binaural alternating mode of presentation averaged 84% correct or better among 18 normal listeners, 2 patients with 8th nerve lesions without brain stem involvement, 9 patients with upper brain stem lesions and 32 patients with unilateral cerebral lesions involving the temporal or parietal lobes. In contrast, 6 patients with lesions located primarily in the caudal region of the pons obtained relatively low scores averaging 36% correct. The difference in performance between the 6 patients with low pontine lesions compared to 9 patients with involvement of the upper pons including the mid-brain and thalamic levels was statistically significant ($t = 3.34$, $df = 13$, $p 0.01$). The data would seem to indicate the following: (1) perception of rapidly alternating speech depends on integrity of auditory centers and pathways low in the pons, (2) low performance scores would seem to implicate involvement in the region of the cochlear nuclei, superior olivary complex and the decussating fibers of the ventral acoustic stria, and (3) lesions in the upper brain stem or cerebral hemispheres would not be expected to affect perception of rapidly alternating speech unless involvement is bilateral or diffuse. An important limitation which must be kept in mind when

using this technique is that peripheral lesions of the cochlea and 8th nerve affecting phonemic discrimination may also disturb understanding of rapidly alternating speech.

Tests employing material which alternates rapidly between the two ears in short bursts may contribute useful information in the localization of brain stem auditory disorder.

"Dichotic Listening Performance in Partial Split-Brain."

Martin L. Lenhardt [Medical College of Virginia Commonwealth University, Department of Biocommunications, Richmond, Virginia 23298]

CV syllables (kindly provided by Kresge, LSU) were presented dichotically to a 13 year old boy prior to and post surgical section of the majority of his corpus callosum. Preoperatively no ear advantage was observed; however, after callosal section a clear right ear superiority emerged. Correct performance approximately doubled for the right ear and fell to chance for the left ear. Voiceless CVs were reported correct more often than voiced, both prior to and post surgery. In addition alveolars were more often reported correctly than labials, which in turn are reported more correct than velars. In single correct response performance was highest when pairs shared voicing preoperative and lowest when pairs shared place. Post operatively sharing place still resulted in the lowest % correct, however, performance was highest when pairs shared neither place nor voice. An analysis of pairs resulting in errors revealed that for: 1) voiceless/voiceless condition 16.6% errors occurred pre and post operatively, 2) voiceless/voiced condition 64.4% errors occurred pre op and 58.4% post op. Thus error pattern did not change after section. These data suggest that callosal section results in suppression of the ear contralateral to the speech processor by removing the interhemisphere relay route. It is suggested, then, that there is a unidirectional pathway for channeling linguistic information from the right hemisphere to the left hemisphere. It would also appear that there is some subcortical ipsilateral suppression by the stronger contralateral pathway post callosal section.

Figure 1: Percent correct identification of CVs for each is about the same level prior to surgery. Post surgery the right ear exceeds the level for both ears confirmed before surgery. Note the left ear is drastically suppressed.

Article and Book Reviews

Tympanometric Detection of Middle Ear Effusion in Infants and Young Children.

J.L. Paradise, C.G. Smith and C.D. Bluestone. Pediatrics, 58-2 [August 1976] pp. 198-210.

This report is a timely reminder that it is the physician who is the ultimate arbiter of whether or not tympanometry is an acceptably valid tool. Here, we find Dr. Paradise, who is among the most knowledgeable pediatricians in the country in otologic problems; Dr. Bluestone, who is among the most knowledgeable otologists in the country on pediatric problems; and C.G. Smith, an able audiologist who appears to have given the requisite support to these dynamic physicians. Together they have reported a thorough study demonstrating the extent of the usefulness of tympanometry in identifying middle ear effusion in young children.

280 children, 10 days through 5 years of age, were given tympanometric tests. All were examined by means of pneumatic otoscopy, and in 107 the findings at myringotomy were reported. Comparison of tympanometry with all of the physical findings showed high correlation in children 7 months to 5 years.

The authors describe five tympanogram curves based on a classification scheme whose primary divisions were based on air pressure-compliance relationships, and whose secondary divisions were based on gradients. For example, in the myringotomy group (177 ears) what we think of as "flat" curves showed 89% agreement with the finding of middle ear effusion. "Normal" curves showed 95% agreement with physical findings. Steep high-negative pressure curves presented 69% agreement with normal ears; "gradual" negative pressure curves were correlated with 85% with effusion. Thus curve gradient proved consistently important in distinguishing effusion from non-effusion. The same was true in the "transitional" category (air pressure at or near atmospheric (-100 to -150) and compliance intermediate (4.5 through 5.5). Here the "steep" transitional correlated 100% with normal ears and the "gradual" transitional correlated 83% with middle ear effusion.

IN the children who were only given pneumatic otoscopic examination (not myringotomy), even higher correlations were reported:

Normal curves: 98% correlation with normal findings;

Steep High-Negative pressure: 72% correlation with normal findings;

Gradual High-Negative pressure: 60% correlation with effusion;

Steep transitional curves: 85% correlation with normal findings.

Gradual transitional curves: 82% correlation with effusion.

"Flat" curves: 82% correlation with effusion.

High Positive Pressure: 57% correlation with normal findings.

The authors state that these statistics afford more precise correlations in the 7 month to 5 year old group, than were heretofore available.

However, in the 43 infants under 7 months of age, only the "flat" or very low curves were associated with middle ear effusion. Curves that in the 7 month or over age group were almost invariably associated with normal ears were in this age group often associated with effusion, i.e., of 66 normal curve types, 32 had effusion. The authors explain this lack of correlation by their observation that the canal walls in many infants can easily be seen to distend under pneumatic otoscopy. Accordingly, they graded the canal wall distensibility of all study subjects on a scale of 0 to +4. When applied to the correlations, they found that distensibility does indeed vary inversely with age, with the sharpest drop-off occurring just after 6 months of age. The authors feel that this high compliance of the canal wall renders electroacoustic measures within the sealed canal unable to differentially identify reduced compliance of the tympanic membrane.

With the exclusion of this younger group, the suggestion is made that tympanometry appears a promising tool as a screening test not only for school age children but also for infants and children in day-care and nursery school settings. They feel that further evaluation of its feasibility and validity is needed for pediatric populations of various ages and backgrounds.

This study proves a welcome addition to the impedance bridge literature, coming as it does from a set of very demanding medical scientists who are in touch with the real world of medical reality.

Mother-Infant Communication and Language Acquisition in Deaf Infants

J.M. Greenstein, B.B. Greenstein, K. McConville and L. Stellini - Lexington School for the Deaf, 30th Avenue and 75th Street, Jackson Heights, New York 11370.

At last, an acceptable investigation demonstrating the advantages of early intervention for the hearing-impaired child! The research team of the Lexington School for the Deaf has put together a neat little study that answers several questions about early language acquisition of the deaf child: (1) How effective is intervention during the first three years of life of the hearing-impaired child?; (2) Is there a "critical period" during which such intervention is maximally effective?; (3) What aspects of the early mother-infant communication system are most relevant to the deaf child's acquisition of language?; and (4) How may early intervention programs be designed to foster those aspects of mother-infant communication or interaction which facilitate language acquisition?

On all counts the study points up the value of earlier initiation

of training programs. Language competence is greater in those whose training is begun earlier; the mother-child interaction improves when language skills are greater; and effective aspects of mother-infant interaction are more highly correlated with the child's language acquisition than with the technical aspects of the mother's language.

The subjects were thirty children diagnosed as severely or profoundly hearing-impaired who had been admitted to the Infant Center of Lexington School prior to their second birthdays. The mean of the pure tone losses (500-2000 Hz) was 98.6. The children were followed through to 40 months of age. Two groups were identified: those who were admitted prior to 16 months of age and a group admitted between 16 and 24 months of age. The formal measures of language skills used were the REEL Scale and the Lexington Preschool Oral Language Assessment. Informal measures were observational assessments of Mother-Infant Communication in six areas: (1) Unstructured Interaction; (2) Behavioral Elicitation; (3) Expressive Language Elicitation; (4) Receptive Language Elicitation; and (5) Imitation Elicitation, and (6) Separation.

The results of the evaluations at 24, 30, 36 and 40 months showed that the children admitted prior to 16 months are consistently superior to the later admitted children in all aspects at all age levels. Statistical significance on all comparisons was p.10, but was largest in expressive language.

The Lexington group proposed that the three most plausible interpretations for the differences are:

(1) That parents who bring their children in earlier for diagnosis and remediation may be more sensitive, concerned, or have other personality characteristics that facilitate their children's language acquisition. It is clear that the group favors this hypothesis. They cite the finding that there were striking group differences between the mothers' language behavior and closeness to the child. A thoughtful discussion of the reciprocal nature of the mother-child relationship illuminates the study.

(2) That there is a critical period for early intervention, possibly at or before 16 months, so that children aided before this age respond better than those aided later. The group felt that the sample studied was too small to test the critical period hypothesis adequately. They suggested that more data on children from hearing homes who are aided at a young age might isolate the maximally effective period.

(3) That some aspects of the training in the intervention program (possible even the mere passage of time after diagnosis) have an additive effect, such that longer exposure to these conditions facilitates language acquisition; or

(4) Some combination of all of the above.

The group discounted hypothesis (3) because the differences in

language competence noted at 24 months did not "wash out even after 16 months of training.

The Lexington group tackled the question of the effects of deaf vs. hearing parents by dividing the children from hearing homes into an Early Admission group (n=9) and a Late Admission group (n=10). This was necessary because the average age of admission for the children of deaf parents was 10 months earlier than for children of hearing parents. In this study the children from deaf families tended to do better in ratings and tests of language competence. The deaf mothers were rated as warmer and the flow of communication between mother and child easier.

However, the children of those hearing parents rated as warmer and more sensitive tended to do as well. The group feels that the nature of the mother-infant interaction is more crucial than the mother's hearing status.

The reports end up with a plea to educate the medical establishment to early intervention programs and to audiological practices. It states "The failure of our current medical services system to provide early diagnosis and referral of hearing-impaired infants approaches the proportions of a national disgrace." And to this we can only say AMEN!

Hearing Conservation: New Challenge for the Team. Proceedings of the Summit Conference on Hearing Conservation sponsored by the Colorado Hearing and Speech Center, Denver, April 26-27, 1976. In the July-August, 1976 issue of Occupational Health and Safety.

Here are gathered together the top echelon in Industrial Hearing Conservation: Dr. Morton Corn, Assistant Secretary of Labor for Occupational Safety and Health Administration; Frank Barnalo, Chairman, OSHA Review Commission; Sheldon Samuels, Director of Health, Safety and Environmental Department, AFL-CIO. To speak with these administrators are such experts as Dr. Floyd Van Atta; A.A.S. President Dr. W. Dixon Ward; Dr. Roger Strassburg of B.F. Goodrich Co.; Dr. Victor Hildyard, otologist; Al Babb and William Sedgely of the Coors Company; Robert Feeney and John Nyberg of Johns Manville and Broyles, Allebaugh and Davis, Inc.; Dr. John Krawleski of the University of Colorado Medical School; and H. Tom Buelter, Executive Director of the Colorado Hearing and Speech Center and the host of the meeting.

The entire issue of the magazine is devoted to the talks given by these knowledgeable people. It provides an encyclopedic source of information on the present status of Hearing Conservation in Industry. Readers will find these articles hard-hitting, lively reading.

Industrial Noise Manual
Third Edition. Size: 8 3/4 x 11 1/2
162 pp., illustrated, hard cover
Published 1975 by American
Industrial Hygiene Association
66 S. Miller Rd., Akron, OH 44314
Price: \$15.75.

This manual presents the principles of sound, discusses noise measuring instruments and noise analysis; surveys medical evaluation methods, examines means of noise control, both personal protection and engineering control of noise and the sound and treats legal aspects and liabilities in detail.

The twelve chapters in the book are: Physics of Sound; Instruments for Sound Measurement; Technique of Sound Measurement; Noise Survey; Vibration; Anatomy and Physiology of the Ear; Effects of Noise on Man; Hearing Measurement; Medical Aspects of Industrial Hearing Conservation; Personal Protective Devices and Hearing Conservation Programs; Engineering Control; and Legal Aspects of the Industrial Noise Problem. A total of 91 noise control case histories are included in the Engineering Control chapter.

**INFO Series 2:
Equipment Designed to
Improve the Communication
Skills of the Deaf.**
National Technical Institute
the Deaf, May, 1976.

This monograph, chiefly written by Donald D. Johnson, presents a variety of equipment recently designed and developed at NTID to help improve the communication skills of its deaf population. Each of seven chapters gives the rationale, as well as the actual design and development, of one or more specific items and its related work space. The items are: (1) Telecommunication systems for the Deaf; (2) A Speech Training Table for the Deaf; (3) An Auditory-Speech reading Training Table; (4) Student Response System; (5) Hearing Aid Center and Shop; (6) A Visual Speech Training Aid (VSTA); and (7) Communication.

A valuable source of current advances in equipment for training the Deaf.

**The Auditory Training Handbook
for Good Listeners**
D. Cassie. The Interstate Printers and Publishers, Inc., 1927
Jackson Street, Danville, Illinois
61832. [Order No. 1762] \$2.50, 64 pages.

A total auditory training program for the deaf and hard-of-hearing is presented in this easy guide to listening. It is aimed at children 3 to 12 years old, with games that progress from gross discrimination, identification of pitch, rhythm, fluency, and voice discrimination.

The booklet includes instructions on the care and treatment of auditory training units and individual hearing aids, as well as the use of tape recorders, musical instruments, plays and puppets.

[Continued on Page 9]

Facts From The Feds

NIH Support for Postdoctoral Research Training

On July 2, 1976, the National Institutes of Health announced the continuation of the Individual National Research Service Award Program to support postdoctoral training in specified areas of biomedical research. Support is provided to individual applicants who compete nationally for awards.

Applicants must be citizens or non-citizen nationals of the United States, or have been lawfully admitted to the United States for permanent residence and have in

their possession a permanent visa at the time the application is submitted. Applicants must also have completed, at the beginning date of the proposed training, the requirements for a doctoral degree.

Applications must be for support in one of the research disciplines specified by the NIH. In the National Institute of Neurological and Communicative Disorders and Stroke (NINCDS), areas that may be of interest to people seeking postdoctoral research training in communicative disorders are audiology, clinical investigation, neurophysiology, otopathology, sensory physiology and biophysics, and speech pathology.

Prior to submission, applicants must arrange for an appointment to an appropriate institution and be accepted by a sponsor who will supervise the training and research experiences. The training institution can be either a domestic or foreign non-profit or public institution, including the NIH. Applications from individuals wishing to study abroad will be approved only if comparable training and research experiences are not available at a domestic institution.

Annual trainee stipends begin at \$10,000 and are increased depending on the number of years of relevant postdoctoral research and/or training experience at the time of the award. No stipend exceeds \$13,200. In addition, the institution where the training is to be taken receives a \$3,000 Institutional Allowance.

The next date for the receipt of applications is February 1, 1977 and those received by that date and assigned to the NINCDS will be evaluated by the National Advisory Neurological and Communicative Disorders and Stroke Council at its meeting in September 1977.

Additional information and applications can be obtained from Raymond Summer, Ph.D., Assistant Director for Manpower Programs, National Institute of Neurological and Communicative Disorders and Stroke, Bethesda, Maryland 20014. Telephone 301-496-9236.

The National Institute of Neurological and Communicative Disorders and Stroke (NINCDS) makes fellowship awards. Individual postdoctoral fellowship awards in audiology and speech pathology were made to: Fredericka Bell-Berti, Edward M. Burns, David S. Isenberg, Barry H. Leshowitz, Roger R. Marsh, Elise F. Masur, Sandra P. Pinkerton, Harry A. Whitaker.

An institutional fellowship award was made to the University of California, Los Angeles with Dr. Vicente Honrubia as Program Director.

Article and Book Reviews (Cont. from Page 8)

Industrial Noise and Hearing Conservation

Julian B. Olishifski and Earl R. Harford, 425 N. Michigan Avenue, Chicago, Illinois 60611. \$24.00

This book has been endorsed by the Council for Accreditation in Occupational Hearing Conservation for use as Reference matter at local courses. The book covers (1) Fundamentals of Noise Problems and Physical Aspects of Sound, (2) Measurement of Sound, (3) Effects of Noise on Man, (4) Measures for Noise Control, (5) The Technician who Screens, and (6) Role of Nurse, Physician and Audiologist in the Hearing Conservation Program.

Survey of Hearing Conservation Programs in Industry

M.E. Schmidek, M.A. Layne, B.L. Lempert and R.M. Fleming, NIOSH, Cincinnati. Supt. of Documents, U.S. Government Printing Office, Washington, D.C. 20402, No. 1733-00085, \$2.00

This survey was conducted by NIOSH to evaluate present Hearing Conservation programs. The results are not encouraging. Engineering and administrative controls were found wanting in most of the industries interviewed. Audiometers failed to meet standards and hearing test facilities were inadequate in 80% of the cases.

Because of the lack of consistency in the training of audiometric technicians it was recommended that standardized procedures be set up, such as outlined in the CAOHC Guidelines.

Earmolds and Associated Problems

The transactions of the 7th Danavox Jubilee Symposium. Supplement of Scandinavian Audiology, 1976. The Almqvist and Wiksell Periodical Co., P.O. Box 62, S-101 Stockholm, Sweden. A 307 page report of the lectures presented at the International Danavox Symposium in 1975.

Quiet, Please, an 8-page booklet by the Metropolitan Washington Council of Governments. Features information on the major sources of environmental noise pollution and its dangers to human health. Helpful hints for citizens trying to reduce noise levels are given. Write to: Metro-

The Healing Hand Man and Wound in the Ancient World.

By Guido Manjo, Harvard University Press, Cambridge, Massachusetts, 1975. \$25.00.

A book to delight the physician, inform the layman, and beguile the medical historian. It started as a pathologist's historical preface to a small paper on inflammation; slowly the preface took over, and for ten years the author searched out the sources describing medical treatment in antiquity. The search led him into the study of hieroglyphics, cuneiform and Chinese characters. Starting with inflammation his study took him to wounds, and from there to biology and history. The book became a history of wounds, and as scholarly a tory of ancient medicine as one will find anywhere.

Dr. Manjo writes as a teacher as well as a scholar, taking time to explain basic biological principles clearly to the non-medical reader. Although only occasional discussions are related to the ear, head or neck, they will have interest for those of us who care to explore our beginnings.

Some 25,000 years ago men of the Aurignacian culture left "signatures" on the walls of the Gargas cave in southern France. These were negative imprints made by blowing black or red color around the hand laid on the rock. Many of the hands lack one or more finger, although the

thumb was spared. (See illustration 1.17.) Manjo at first speculates that the whole group suffered from Raynaud's disease, a condition that could have led to gangrene of the hands in that cold climate. But similar hands turned up in the Maltravieso cave in central Spain, with a milder climate. The next possibility was ritual amputation. Both African Bushmen and several Indian tribes in Canada have been known to cut off fingers as a form of sacrifice. But some of the missing fingers in the paintings appeared to have been retouched, i.e., painted over, so the fingers seemed more of a code, perhaps for hunting. There is a code used today by the Bushmen that could represent the same kind of messages. (Illustration 1.19.) Was this the first beginnings of sign language, and of communicative writing?

Boxing was a popular sport in Hippocrates' time and the resulting cauliflower ears were portrayed in Greek scenes and sculpture. Aristophanes coined the term "oto-kataxi", or "ear-breaker", for boxer. Manjo projects what the Hippocratic iatros (physician) might say to such a patient: "As to your ears, almost anything I could do would make matters worse. It is sometimes a good remedy to apply nothing at all, and this is true not only for the ears. Even a bandage would hurt. Later on, if pus forms, I may have to cut, and maybe even burn a hole in the ear with the cautery, though that would leave you with one ear smaller than the other. In the meantime we will work at preventing suppuration: take this to purge you from above with a

mild method called syrnaism, according to which you load your stomach with a large amount of salt, water and radishes, then throw it up. After that you can go home, and do not sleep on your ears."

Many similarities are found between ancient treatments and modern techniques: Rebuilding the nose with forehead flaps is a modern operation; it was described by Sushruta in India, certainly as early as 1000 A.D. Two short tubes were used in place of the nostrils, as still used today.

A description of Galen's discovering of the recurrent laryngeal nerve is gruesome: While vivisectioning a pig that was squealing loudly he cut one of two "inferior laryngeal nerves". The squealing stopped. He repeated the experiment on dogs, goats and other animals. The result was always the same. Manjo feels that Galen should be relegated to scorn.

Other ancient medicines are also covered in detail: Egyptian, Grecian, Indian and Chinese. The basic meaning of Chinese acupuncture was drainage.

The Greeks also believed in drainage to restore the balance of the four humors of the blood, but they literally drained the blood from the veins. The Chinese solution was that there were a set of imaginary vessels or "meridians" containing not blood but ch'i, denoting energy. It could either be drawn out or replenished (inward) by needling the right ch'i vessel. Thus the needling could be a form of drainage of energy, or of replacing it.

One of the mysteries is that with all the imagination of Hippocrates, Galen, Sushruta and the others, none conceived of the use of the hemostatic tourniquet to stop blood. It was not until man was shooting at his brothers with guns that the tourniquet was finally discovered.

Galen in one of his writings warned against the poison contained in the human bite. For it he recommended treatment with ear wax, preferably from the ear of the bitten.

So if you don't enjoy this fascinating book, at least you have found a use for ear wax. Try it—the book, I mean.

M.P.D.

Hearing Aids

Specs Standards

Approved

The American National Standards Institute (ANSI) approved the new Standard Specification for Hearing Aid Characteristics on July 23, 1976, according to Sam Lybarger, chairman of the ANSI working group. The new standard had already been approved by the Acoustical Society of America.

The correct designation for the standard is: Acoustical Society of America Standard 7-1976 (ASA Standard 7-1976/ ANSI Standard S3.22-1976) Specification for Hearing Aid Characteristics.

This standard ASA STD 7-1976, is available at a single-copy price of \$7.00 prepair (a handling charge of \$2.00 is required if payment does not accompany order).

Make checks payable to the ASA Standards Secretariat. This standard and other standards listed in the ASA Standards Catalog may be ordered from the following address: Back Numbers Department, Dept. STD., American Institute of Physics, 335 East 45th Street, New York, New York 10017, Telephone (212) 685-1940.

Corti's Organ salutes Sam Lybarger, his working group, and the ANSI for an expeditious job in putting out these standards in such a short time. Few government agencies work with such dispatch, as we see in OSHA's heel-dragging on the noise standards.

Third International Impedance Symposium

The III International Symposium on Impedance Audiometry was held in New York City on September 29, 30 and October 1 and 2. In spite of a late change of location for the Symposium from Philadelphia to New York City, the program drew 140 registrants as well as 35 faculty members. The American Electromedics Corporation sponsored the Symposium while James Jerger and Jerry Northern served as Scientific Program Co-chairmen.

The featured speakers were truly international coming from Europe and South America. They included Erik Borg, Stockholm, Sweden; Andrea Bosatra, Trieste, Italy; Denzil Brooks, Manchester, England; Gisle Djupesland, Oslo, Norway; James Jerger, Houston, Texas; Wolfhart Niemeyer, Marburg/Lahn, Germany; M. Maurice Rainville, Paris, France and Juan Tato (h), from Buenos Aires, Argentina.

Workshop panels each afternoon offered program registrants an opportunity to choose attendance at two of three discussions featuring some 25 American impedance experts. Discussions centered around Future Directions and Research Applications for Impedance Measurements, Otologic Applications of Impedance Audiometry, and Pediatric and Screening Implications of Impedance Audiometry. The Workshop panels were chaired respectively by Terry Wiley, from the University of Wisconsin, Robert Keim, from the University of Oklahoma Health Center and Geary McCandless of the University of Utah Medical Center.

Unique features of the Symposium and Advanced Impedance School included two practicum sessions whereby round-table groups of registrants matched selected audiometry results with appropriate sample audiometric patterns to reach diagnostic conclusions. Group table decisions were reached concerning the best match of impedance and audiometric patterns, while Dr. Jerger provided the actual answers to each diagnostic problem case. A

Johnson Named President Of Danavox

The Danavox International Company of Copenhagen has announced that James Johnson, formerly president of Zenith Hearing Instruments, has been appointed president of Danavox, Inc., the U.S. subsidiary in Minneapolis. He will also serve as a member of the Board of Directors.

An A.A.S. member, Johnson also holds memberships in the Acoustical Society of America, American Marketing Association, Audio Engineering Society and IEEE. He received his B.S. in Electrical Engineering from Purdue and his M.B.A. from the University of Chicago.

"Meet-the-Faculty" cocktail party and a banquet with wandering musicians contributed to the organized social aspects of the Symposium.

Proceedings from the III International Symposium on Impedance Audiometry are currently in press and will be available for a fee from the American Electromedics Corporation, 145 Palisade Street, Dobbs Ferry, New York 10522.

Faculty for the III International Symposium on Impedance Audiometry. Left to right, top row: I. Klar, E. Borg, F. McCandless, R. Keith, P. Rosenberg, R. Harrison, J. Sanders, D. Hogan, T. White; middle row: A. Bosatra, J. Lapidus, S. McLinn, C. Bluestone, E. Rock, G. Djupesland, T. Wiley, W. Fee, R. Margolis; R. Keim, G. Neely, C. Jordan, Ms. Bosatra, J. Cooper, L. Wilber, J. Jerger, S. Jerger, J. Northern and W. Niemeyer. Not shown are D. Brooks, M. Rainville and R. Sullivan.

BHI Is . . .

(Corti's Organ is happy to print this article on the Better Hearing Institute as a retraction of our statement in the April issue of C.O. that the BHI is "an organization of the hearing aid industry". Their Director of Public Information informs us that it is a totally independent organization, not of the hearing aid industry. We apologize. The error was due to the fact that we observed BHI's Board of Director to be composed entirely of representatives from the hearing aid industry.)

Questions and Answers About The Better Hearing Institute

Q. What is BHI?

A. Better Hearing Institute (BHI) is a nonprofit educational organization dedicated to informing the hearing impaired, their friends and relatives, and the general public about hearing loss and available medical, surgical, and amplification assistance.

Q. How many hearing-impaired Americans are there for BHI to serve?

A. Hearing loss is our nation's number one handicapping disability. According to a U.S. Public Health Service survey, at least 14.5 million Americans, including three million school-age children, suffer from hearing disorders. Only an estimated 3.5 million have sought help.

Q. Why are BHI education programs so vitally needed?

A. Because more than 11 million Americans suffer from uncorrected hearing handicaps. Most of these people could be helped. But first they need to know that nearly everyone with a hearing loss can benefit by medical or amplification assistance. They also need to know more about such help and how to obtain it.

Q. What is it that BHI hopes to accomplish?

A. BHI's goal is, through its information and education programs, to remove the stigma currently attached to wearing a hearing aid and to help eliminate hearing loss as a personal handicap in everyday life. A major BHI objective is to help persons with normal hearing protect themselves against preventable hearing impairments—for example, by alerting them to avoid extended exposure to noise.

Q. How does BHI disseminate information?

A. Primarily through mass communication—public service radio and television announcements, news and feature stories in the nation's broadcast and print media, audiovisual aids, exhibits, and a speaker's program. BHI distributes hearing help booklets, a newsletter, and other literature. In addition, BHI an-

[Continued on Page 11]

Computer Management Educational Hearing Conservation Program

screening programs, we saw the need to provide a practical means of recording tympanometry findings and pure tone results for schools which would be easy to understand and thereby upgrade local hearing screening programs.

"During the research and development of our program we realized that even if the high percentage of false positives and false negatives could be reduced by using impedance measures, we couldn't assume that those children who were identified would get treated. Thus, this new concept would be no better than existing archaic programs in terms of early identification and treatment of children with suspected ear disease."

Mr. Lapidus reported, "We have developed a system of testing and data recording procedures that can be easily learned by existing personnel already performing hearing screening in local public schools."

The H.E.A.R. Program provides explanatory letters to parents about procedures, case history and test forms to schools and consultant services. The entire program is computerized. Printouts are in two forms: one version specifies tympanogram patterns, stapodial reflex and pure tone thresholds as well as static compliance measurements - for the audiologist; the second version specifies the degree of suspected hearing problem and middle ear aberration in simple, easy-to-understand sentences - for the school nurse, special educational directors, and other educational personnel. In addition, recommendations on every child for each successive test day are listed. Appropriate statistics for each school and district are also indicated.

"Perhaps the most beneficial result of this concept of computer management were the letters printed to parents and physicians by the computer," Mr. Lapidus said.

"No longer is the local school nurse bogged down with coordinating data and typing letters. With composite readouts the nurse is able to quickly determine who may have a suspected problem and what the audiological recommendations are. Pre-printed letters can be mailed to parents with the appropriate results and recommendations for their child."

Computer Management has enabled Metropolitan Centers to more accurately identify a child with a potential hearing problem and alert parents and physicians as quickly as 2 to 4 days after the testing. In other programs, children are not examined by a doctor for as long as twelve weeks after testing because of the paper work involved. By then, the condition may have changed and the physician may dispute test findings. All too often the physician and the parent lose confidence in the school screening program.

"We think we're on the right road in helping to overcome these

drawbacks of traditional programs," Lapidus emphasized. "H.E.A.R. enables us to help school systems, head start and welfare projects; even HMO and multi-phasic medical screenings to provide a better means of identification, treatment and follow-through of suspected hearing and middle ear problems."

Mr. Lapidus also said there was more to come. "The more involved we get, the more we realize how much electronic data processing can help us. We now have a method of monitoring the accuracy of test results as well as the test procedures."

"For the first time, effective audiological services can be provided to rural areas. The H.E.A.R. Program can be run in rural schools and supervised by only a few periodic visits by one audiologist serving a wide area. The school nurse can contact the audiologist by phone to ask questions, while both can refer to their computer readouts. The audiologist can also help upgrade testing procedures by referring to specific cases and specific results."

And still there's more. Mr. Lapidus said, "We are now in the process of finalizing the means of periodic computer updates listing those children who have been to the doctor, for example; listing the diagnosis and correlating medical and audiological test findings in order to constantly re-evaluate pass-fail criteria."

The computer system will also specify those students who have not followed through on their recommendations, thus enabling local personnel to immediately contact the family.

H.E.A.R. still maintains human control and intervention during this entire process. Even though the computer now prints out retest forms for all children who need further testing with retest recommendations (i.e. pure tone threshold right ear, tympanometry retest each ear, etc.), the final decisions are still made by the tester.

"We think this program is flexible and dynamic enough to begin to provide a better approach to the essential task of accurate early identification and follow-through of potential auditory disorders in children."

"The statistical gathering ability programmed into this entire package has allowed us to accurately assess the real answers to numerous questions of performance level in school systems of controlling ear disease and its potential for contributing to learning disabilities. The automatic statistical printout following the complete testing of a school system has given school boards and audiological personnel the kind of information never before attainable in an accurate, concise and complete manner."

Comments and questions regarding the H.E.A.R. Program may be directed to: Joel Lapidus, M.A., Administrator of Field Services, Metropolitan Centers, 1507 Washington Street, West Newton, Massachusetts 02165.

BHI...

[Continued from Page 10]

swers thousands of telephone and written requests for information annually.

Q. Describe BHI's TV and radio public service program.

A. BHI public service announcements feature celebrities with corrected hearing handicaps, including Academy Award-winning best actor Art Carney, Washington Redskin halfback Larry Brown, comedian Norm Crosby, actress Nanette Fabray, Governor George Wallace, and singer Johnnie Ray. In the spots, each acknowledges his or her own hearing disorder and encourages others who suspect a problem to seek help. In addition to the celebrity PSAs are several scenario spots aimed at specific audiences or special topics. BHI public service announcements are aired by all major networks—NBC, CBS, ABC—and hundreds of local stations across the country. The theme: You should hear what you're missing.

Q. What kind of booklets does BHI produce?

A. One of the Institute's most successful booklets is "They Overcame Hearing Loss," featuring the personal success stories of 12 prominent hearing-impaired Americans from all walks of life—television, football, theater, boxing, movies, government, and business. Another effective BHI booklet is "Sounds or Silence? We Chose Hearing Help." Using personal case histories and photographs, it features everyday people telling about their own hearing problems and where they went for help. Interspersed among the case histories are informative vignettes. BHI also distributes hearing help literature prepared by other organizations, such as the Council of Better Business Bureau's "Facts About Hearing Aids."

Q. Does BHI offer any special assistance or information to consumers?

A. One of BHI's public service programs is a toll-free Hearing HelpLine. HelpLine provides assistance of hearing field professionals, consumer affairs personnel, law enforcement officials, and consumers in handling questions, suggestions, and complaints about hearing loss, hearing help, hearing aids and hearing aid services.

- 30-31 Western Regional Auditory Approach Conference: The Hearing-Speech Chain - A.G. Bell and Listen Foundation, Sponsors; Dr. Mark Ross, Leahea Grammatico, speakers. Hilton Hotel, Denver, Colorado.

NOVEMBER 1976

- 2-5 American Speech and Hearing Association, Houston, Tx.
- 4-11 15th Pan-American Congress of Otolaryngology and Bronchoesophagology, New Orleans. Write to Creative Associates, 5005 Newport Drive, Rolling Meadows, Illinois 60008.
- 6-7 5th Symposium on Polytomography of the Temporal Bone. Wright Institute of Otolaryngology and Community Hospital. For contact: J. William Wright, Jr., M.D. Wright Institute of Otolaryngology and Community Hospital, 1500 N. Ritter Avenue, Indianapolis, Indiana 46219.

Q. Could you describe BHI's speakers program in greater detail?

A. A major part of BHI's speaker's program is its audio-visual presentations. "You and Your Hearing," the Institute's first slide/ cassette show, is a basic, general-purpose presentation designed for broad usage. "Silence is Lonely," a new presentation, is targeted to the special needs and interests of senior citizens. In addition to slide shows, BHI distributes sample 10- to 20-minute general information speeches on hearing loss and hearing help.

Q. Who is on the BHI Advisory Board and what is its function?

A. The BHI Advisory Board is comprised of distinguished ear specialists, hearing field leaders, celebrities with hearing loss, and others prominently associated

with the hearing impaired. Advisory Board members provide vital input into Institute projects, as well as spokesmen for BHI's speaker's bureau, literature, TV and radio appearances, and other Institute projects.

Q. Does BHI ever cooperate with other hearing organizations?

A. We refer people to other hearing educational centers for certain types of information and also to direct providers of hearing help services. We distribute literature developed by various hearing organizations. Perhaps the best example, though, is Better Hearing Month—a cooperative effort conducted each May by BHI and hearing organizations across the country to focus public attention on hearing loss and available hearing help. For this program, BHI prepares a comprehensive 100-page kit of ready-to-use communications tools for use by hearing field personnel at the local level. Nationally, BHI initiates a barrage of print and broadcast publicity.

Q. How long has BHI been in existence?

A. BHI formally began in April, 1973.

Q. What is the Institute's IRS classification?

A. BHI is a nonprofit educational organization and as such is classified as a 501(c) (3) (exemption # 42-1018642) by the Internal Revenue Service. Tax-deductible contributions from all sources are welcome. Help others to hear what they're missing. Send your gift today.

Calendar of Events

- 12-16 International Symposium on Child Language Acquisition, Acapulco, Mexico. Write to Dr. Juan Garrasco-Zanini, Instituto Mexicana de La Audicion Y El Lenguaje, A.C. Avenue Professor 141-A, Mexico, D.F.
- 16, 17, 18 Annual Meeting of Society for Ear, Nose and Throat Advances in Children. New Orleans, Louisiana Maison Dupuy Hotel. Write to Dr. Basharat Jazbi, The Children's Mercy Hospital, 24th at Gillham Road, Kansas City, Missouri 64108.
- 16-19 Acoustical Society of America, San Diego, California.
- 20-23 American Speech and Hearing Association, Houston, Tex.

FEBRUARY 1977

- 20-23 Ear Surgery Course, J. Brown Farrior, M.D., Tampa, Fla.

MARCH 1977

- 5-12 Medical Audiology Workshop, Vail, Colorado. For information write to: Box B210, 4200 E. 9th Avenue, Denver, Colorado 80262.
- 13-19 11th World Congress of Oto-Rhino-Laryngology, Buenos Aires, Argentina. For information write: Dr. Alfredo Cordero, Secy., Av. Rocque S. Pena 1110-2° Piso, Buenos Aires.
- 14-17 NOISEXPO '77, The National Noise and Vibration Control Conference and Exhibition, Holiday Inn, O'Hare/ Kennedy Chicago. Technical papers, films and other presentations are solicited: NOISEXPO '77, 27101 E. Oviatt Road, Bay Village, Ohio 44140.

APRIL 1977

- 14-16 16th Annual Electronystagmography Course, New Orleans. Contact Wallace Rubin, M.D., 3333 Kingman Street, Metairie, Louisiana 70002.

MAY 1977

- 9-11 1977 IEEE International Conference on Acoustics, Speech Signal Processing, Hartford, Connecticut. Write to Harvey Silverman, IBM-T.J. Watson Research Center, P.O. Box 218, Yorktown Heights, New York 10598.
- 17-20 Acoustical Society of America, State College, Pennsylvania.
- 25-29 White House Conference on Handicapped Individuals, Washington Hilton Hotel, Washington, D.C. Write to: Jack F. Smith, White House Conference on Handicapped Individuals, 1832 M Street, W., Suite 801, Washington, D.C. 20036

AUGUST 1977

- 15-18 Symposium of the International Electric Response Audiometry Study Group, Hebrew University, Jerusalem, Israel. For information write to: Prof. H. Sohmer, ERA Organizing Committee, Medical School, P.O.B. 1172, Jerusalem, Israel.

President's Message . . .

[Continued from page 3]

not reduce noise levels to 90 dBA. Although this posture has recently been successfully challenged by a can-manufacturing industry, at the moment the burden of proof remains on industry to show infeasibility, rather than proof of feasibility being on the shoulders of OSHA. As any ex-debator knows, that's dirty pool, son.

Why has the Department of Labor taken such an unyielding stand against plugs and muffs? One reason they offer is because some workers don't like to wear them; another, because it is possible to wear them incorrectly, either by accident or design. Not only must the employer identify a hazard and make it possible for the worker to avoid it, say our rulers (the politicians and bureaucrats who are busy minding everyone else's business because they have none of their own), he must eliminate the hazard no matter the cost. The employer may not have promised the worker a rose garden, but good ol' Uncle is going to make sure he supplies it anyway. And if this is not possible, then the employer must act in loco parentis and make sure that his "children" are good little boys and girls and wear their ear protection dutifully.

Well, those are the main points of contention in the present hearings. Workers and their representatives would like all noises reduced to non-hazardous levels (and a little lower) regardless of cost; their evidence consists mostly of the shortcomings of ear protection. Industry would like to spend as little as possible, to avoid the inevitable price increases that could put them at a disadvantage in competition with other products and foreign manufacturers. The thrust of their testimony is that hearing conservation programs can eliminate noise-induced hearing loss and that levels below 90 dBA represent a negligible hazard. As a consumer and taxpayer, yet one who wants noise-induced hearing loss stamped out (at least that loss caused by actions other than one's own), I hope that a reasonable compromise can be reached, for every worker to avoid noise-induced hearing loss

if he chooses to do so.

Noise control experts, not too surprisingly, are solidly behind OSHA, but manufacturers of muffs and plugs oppose the stricture—unreasonable, in their view—against their products. I suppose that audiologists, or at least those engaged in industrial audiometry, should also be opposed to the Department of Labor ban-the-muff crusade, and particularly to an 85-dBA regulation. If noise levels were reduced to 85 dBA, there would be no reason to continue monitoring the hearing of industrial workers, as any losses that developed would have to be attributed to presbycusis, nosocausis, or sociacausis—the influence on hearing of the aging process, disease, or the noises of everyday life, respectively. However, since reduction to 85 dBA or even 90 dBA of all industrial noises is far, far in the future, it is safe to say that we need not worry that our audiometers will soon be gathering dust.

One more of the questions addressed by the proposed regulation (although not directly involved in the BBN report) is important to our field: the criterion of a "significant" shift in hearing and what is to be done when it occurs. As published in 1974, the proposed criterion would be an average shift of more than 10 dB at 2, 3, and 4 kHz, relative to the original baseline audiogram, which as far as I can tell from the meager published literature would not occur due to random variability in serial audiometry more than 10% of the time. However, I have heard rumors that an alternative criterion is being considered. Let us hope that they don't do something stupid like adopting a criterion of a 10-dB shift at any frequency, an event that requires retesting and reinstruction on the use of ear protection; I suspect that a third or more of all workers would have to be so retested.

As I say, there will probably be no hint of the final form of the OSHA regulation until after the election. Indeed, if it is necessary to appoint a new Secretary of Labor, he might have to have still another round of hearings. Perish the thought!

Roger M. Angelelli Reports on Successful European Study Tour

The "XIII" International Congress of Audiology was anything but unlucky. From October 18 to 22, 1976, approximately 250 members gathered in the Palazzo dei Congressi in Florence, Italy,

to present their scientific papers. Participants represented such countries as Sweden, Belgium, United Kingdom, USA, Italy, France, Norway, W. Germany, Denmark, Japan, The Nether-

lands, Poland, Finland, Spain, Yugoslavia, Mexico, Austria, Israel, Czechoslovakia, Hungary, Rumania, Greece, Thailand, Egypt, Canada, Switzerland and Bulgaria. The working languages of the Congress were English, French and Italian. Simultaneous translation in these languages were provided by a skillful team of female translators.

The Palazzo dei Congressi was an impressive structure blending the "old" architecture, where several conference rooms were located, with the new design of the twentieth century. The new structure housed the magnificent oval-shaped auditorium with star-studded light dimmers in the ceiling, and comfortable chairs with sliding armrests, under which were jack plugs for earphones. A closed-circuit television network was in operation to give information regarding the speakers in session in different rooms of the Palazzo. This system was also used to announce bus departures for various tours.

The major areas covered in the program included: (1) Advances in acoustic impedance measurements, (2) Effects of noise, (3) General audiology, (4) Peripheral coding of auditory signals, (5) Inner ear: ECOG, (5) Impedance measurements, (6) Ototoxic drugs: psychoacoustics; embryology, (7) Auditory processing of speech and its implications with respect to prosthetic rehabilitation, (8) Brain-stem and cortical auditory responses, (9) Hearing aids and related problems.

Florence or as the Italians refer to it, "Firenze", is a city of approximately 500,000 inhabitants. It is a city of many churches, of magnificent splendor and serenity constructed before Christopher Columbus embarked upon his voyage to the new world. One is overwhelmed

New Name for AAS?

"A rose by any other name..."

Recently a great deal of concern has been expressed over the name of our organization, the American Audiology Society. Opposition to the name comes primarily from member audiologists who feel that the generic name "Audiology" in the name of our organization is inappropriate. They argue that the AAS name is inconsistent with the stated interdisciplinary nature of the Society. The concerned audiologists apparently feel a proprietary right to the name of their profession which they are reluctant to share with a multidisciplinary society. Public confusion can exist when individuals engaged in allied disciplines are referred to be "audiologists" because of their membership in the American Audiology Society.

Problems regarding the current name of the Society came to the forefront in recent federal investigations. Representatives from the American Speech and Hearing Association have been involved in depositions and testimony during 1975 and 1976 during which confusion has been apparent to the interrogators about the role of ASHA and the role of AAS. This confusion has been recorded in direct testimony between Kenneth O. Johnson, Executive Secretary of ASHA, and the U.S. Patent Office over the petition of ASHA to have NHAS's use of the term "Certified Hearing Aid Audiologist" declared illegal. The Federal Trade Commission hearings in Washington, D.C. regarding the proposed trade regulations for the hearing aid industry brought out the fact that hearing aid

dealers might represent themselves as "audiologists" because of their membership in AAS.

An audiologist is defined by ASHA, Medicare, Medicaid, and 29 state licensing bodies in terms of specific academic requirements, regulated experience criteria, and successful passing of a nationally standardized comprehensive written examination. The definition of an audiologist does not require membership in ASHA, but ASHA will supply letters of equivalency to applicants who meet the standards by which audiologists are defined. All definitions are related to standard curricula in Departments of "Audiology and Speech Pathology".

Historically, the AAS name was established by the Executive Committee in June of 1973. Only three members of the Executive Committee at that time (three audiologists) expressed opposition to the name American Audiology Society. The name was selected so that the AAS could pattern itself after the International Audiology Society. There is now apparently some conflict in this issue since AAS and ASHA have both petitioned the International Society to be admitted as the audiology representative from the USA.

A Task Force of Audiologists met during the summer of 1976 in Washington, D.C. under ASHA sponsorship to generate resolutions regarding the future directions of the audiology profession. The Task Force, including a number of AAS members,

(Continued on page 4)

A.A.S. to Ballot On Name Change

The Executive Board of A.A.S. agreed at the Las Vegas meeting to submit a constitutional name change proposal to the membership. Before this is done, however, a straw ballot is to be taken on which name shall be proposed. This issue of Corti's Organ contains a ballot on page 11, for the members to indicate a preliminary preference for or against a change, and a choice of names that might be proposed.

The Interrogatory section will be devoted to opinions of the Executive Committee regarding name changes. In addition, C.O.

has invited Jerry Northern to describe the background for considering a change. His article "New Name for AAS" is featured on page 1. The Interrogatory begins on page 3.

After reading these articles, please cut out the ballot and return it to Ross Roeser as soon as possible. This is not a final vote on a name change, but it will guide the Executive Committee in sending out a By-Law change proposal to the membership.

We need feed-back from every member of A.A.S. Please care, one way or the other, about the organization's future.

Roger M. Angelelli at JFK before departure to Italy.

A Janus Message

As a casual participant in the evolution of medicine, it's become apparent to me that we've lost touch with the past. The lessons and mistakes of our forebearers, no matter what our field of interest, serve as a scaffold, bridging the ignorance with progress. If we continue to ignore the ages as we do the aged, then we are squandering a huge reservoir of experience, talent and wisdom.

That's why the Politzer Society was formed in 1975. Composed of members interested in the history of otolaryngology and related fields, the group serves as a vehicle for the expression of the past to be appreciated by the present. Like the Greek figure Janus, that two headed sage, the membership of the Society strives to see where we are going while always looking behind. Indeed, what's past is prologue and we all need to appreciate that fact. Let's not be overwhelmed by technology to the exclusion of the lessons of times. An understanding and sensitivity for those individuals who comprise the roots of our speciality will help otolaryngology grow, fertilized with individuals nurtured by history.

It's been said that the only thing we have learned from history is that we don't learn from history. In these times when we need to summon all the wisdom of the past as possible, it behooves those interested in the progress of mankind to prove that aphorism false.

Take time and look where you have come from! It's a sad fact of medical life that efforts at "progress" are sometimes mere reduplication of past achievements gone unrecognized. Maybe our supposed intellectual evolution is attributable to sophisticated advertising, Madison Avenue magic and journalistic "hype", rather than good fresh ideas.

The Politzer Society offers you a ticket to the past, an opportunity to meet and hear about those who constructed the superstructure of otolaryngology. Remember, you have an appointment with history. Be sure and keep it.

Arlen D. Meyers

President, Politzer Society
(For information on membership, write to Dr. Meyers at: Dept. of Otolaryngology, University of Colorado Medical Center, 4200 E. 9th Avenue, Denver CO 80220)

Gerber is New Prexy for SENTAC

At its fourth annual meeting, the Society for Ear, Nose and Throat Advances in Children (SENTAC) has elected an audiologist to its presidency. The new president of SENTAC is Dr. Sanford E. Gerber who is Professor of Audiology and Coordinator of the Speech and Hearing Center at the University of California, Santa Barbara. All of Dr. Gerber's predecessors in this office have been otolaryngologists; and his election marks the kind of close cooperation and mutual respect which exists between our professions. Also at that meeting in New Orleans, Dr. M.C. Culbertson of Dallas was elected Vice-President. The continuing secretary-treasurer is Dr. B. Jazbi of Kansas City. Also two new trustees were elected: Dr. Michael Seidemann (an audiologist from New Orleans) and Dr. William Moran (an otolaryngologist from Oklahoma City.)

SENTAC is a multidisciplinary society oriented toward the advancement of pediatric-oto-

laryngology -audiology- speech pathology.

The convention began with a Mississippi River sternwheeler cruise the evening of November 15th. The formal meetings began November 16th with presentations by local New Orleans participants in the areas of pediatric otolaryngology, pediatric allergic problems related to middle ear disease, pediatric voice disorders, and pediatric audiological issues in middle ear measurements. The presenters for that session were George D. Lyons, Ray J. Lousteau, Michael Sly, Jeannette K. Laguaite, Donald Ramp, Michael F. Seidemann, and Greg Givens. Meetings on November 16th adjourned at noon so that the attendees could participate in a city tour around the New Orleans area that afternoon. On November 17th there were several presentations in pediatric otolaryngology in addition to the following presentations in pediatric

JOBS, JOBS, JOBS

No, we don't have any available, but we'd like to list yours. Need a Friendly Otolaryngologist in your medical group, or a competent Audiologist in your practice, hospital or clinic? Send in your job requirements and the old ORGAN will try to get you a body.

Zwislocki Receives International Prize

Milan, Italy - Dr. J. Zwislocki, of the Institute for Sensory Research in Syracuse, New York, has been unanimously awarded the 1976 Centro Ricerche e Studi Amplifon Prize (approximately 6,000 dollars). This prize is the most important award established to honor audiological scientists.

This announcement was made by Mr. A.C. Holland, president of CRS Amplifon.

"Dr. Zwislocki," Mr. Holland said, "has been unanimously voted by all the 15 members of the Award Committee because of his contribution and research on cochlear coding and on the sensory perception of the auditory message."

Dr. Zwislocki was presented the CRS Amplifon International Prize on the 25th of November 1976 in Milan; two lectures were also organized at Centro Ricerche e Studi, with Dr. Zwislocki discussing

his auditory theory both with the otologists and with the bioengineers.

CRS International Prizes have been awarded since 1973 to:

- Prof. Tokuro Suzuki, Shinshu University, Matsumoto, Japan;
- Prof. Erik Wedenberg, Karolinska Institute of Stockholm, Sweden;

- Prof. Hallowel Davis, Central Institute for the Deaf of St. Louis, U.S.A.;

- Madame Suzanne Borel Maissonny, Centre Experimental Orthophonique and Pedagogique of Paris, France;

- Prof. James Jerger, Baylor College, Houston, Texas, U.S.A.

"I am extremely proud," A.C. Holland commented, "That the name of such an eminent scientist as Dr. Zwislocki will from now appear amongst those of the other world-famous figures to whom CRS has granted its prize."

The new president of SENTAC, Sandy Gerber, says everything's coming up roses!

Editorial

In view of the fact that Aram Glorig was the prime force behind starting the American Audiology Society, and is one of the past presidents, we have asked him to comment on the name change issue. MPD-RHR.

AUDIOLOGY—WHAT IS IT?

Humpty Dumpty says, "Words mean what I want them to mean." The crux of our present dilemma is, who is Humpty Dumpty in this case? If one uses Dorland's Medical Dictionary, audiology is defined as "the study of hearing, including treatment of patients with impaired hearing." This rather broad meaning presents considerable confusion since only physicians are licensed to treat patients in the traditional sense. Dorland's Medical Dictionary also defines otology as "the sum of what is known regarding the ear." But Humpty Dumpty, in this case, has given it the flavor of medical and surgical treatment of the ear.

The Humpty Dumpty of audiology (ASHA) on the other hand is hoping to restrict the field of audiology only to those who hold, or are eligible for, ASHA certification.

The audiologists of the United

[Continued on page 4]

Letters to the Editor

David P. Goldstein: An issue has recently come to my attention about the A.A.S.

At recent FTC hearings, ASHA representatives have had to defend the notion that the term audiologist only applies to persons having completed a particular curriculum. Hearing aid people would like this term to apply to their salesman. In their argument against restricting the term audiologist to those who have completed a particular curriculum, the dealers cited A.A.S. as support for their position that anyone can use the term audiologist. They based their contention on use of the term audiology in the title of an organization which accepts people from many disciplines including hearing aid dealers who are not trained as audiologists.

While I support the goals of

A.A.S. I worry if its title is being used to subvert other related and worthwhile goals. I understand that some of the founding fathers (should I say persons) expressed concern over this potential problem. Now that their fears have come to pass I would like to suggest that the Executive Committee change the title of the organization to more appropriately reflect the varied disciplines it embodies.

Earl R. Harford: I cannot endorse strongly enough the position to change the name of A.A.S. In no way should we allow A.A.S. to be used by the hearing aid sales element as rationale for hearing aid dealers without credentials using the designation of "audiologist." It is obvious that this is the case; consequently we must change the name of A.A.S.

THE INTERROGATORY

Corti's Organ has asked the members of the Executive Committee to respond to the questions: "Do you favor a name change for AAS? Why? If you favor a change, what name would you prefer?"

Jaime T. Benitez: Please be advised that I do not favor changing the name of our society. Therefore I would not like to consider any of the proposed names.

Leo G. Doerfler: My only comment is that any change which will clarify language and its meaning rather than further degrade it would be welcome. If the use of the term *Audiology* in the name of our Society tends to confuse the identity and/or competencies of our members, and I believe this may be the case, then a change in title is in order.

David A. Dolowitz: I feel that the present name best exemplifies the effort to unite all aspects of the field of audiology and do not feel that we need concern ourselves about hearing aid members and using the name illegally. It is more important that we concentrate on seeing good Federal and State hearing aid laws.

A. Bruce Graham: The name *Audiology* has come to mean the profession rather than just an interest in hearing; therefore, I can see the need to drop that particular word because the purpose is still sharing the ideas with otolaryngologists, audiologists, and those interested in the production of hearing aids. I think the word "hearing" should certainly be a part of the Society name. The American Hearing Society and the National Association of Hearing Speech Action which was formerly the American Hearing Society, The American Association for Hearing and the American Hearing Association are too close to ASHA with just one item removed. Of those suggested, my favorite is the American Society for the Study of Hearing which would give the initials ASSH.

J. Donald Harris: I vote for a change in the name to "The American Auditory Society."

Gilbert Herrer: I am greatly concerned about the confusion now created in the United States by the use of the term *Audiology* in the Society's name. It does allow those non-audiologist members of the society, who choose to do so, to imply they are audiologists (definition as is generally accepted in the United States) when such is not the case. I do not believe that our learned Society should be placed in a position to allow this to happen. I, along with many others, joined the Society to benefit from the interaction with people from a variety of disciplines. I expected the Society would be a learned one and not involved in professional political business. As an audiologist, the latter for me would be taken up through the American Speech and Hearing Association.

I concur that a change in the Society's name seems in order to avoid misinterpretation of the term audiologist, and to avoid the

Society's being a battleground between disciplines interested in hearing impairment. On the contrary, a name change would lend itself to just the opposite: a society where people from varied interests can interact and learn from each other.

I could see our Society's name changed to such titles as: American Auditory Society or American Society of Audition without compromising its interdisciplinary character and intent.

I sincerely hope the Executive Committee gives serious thoughts to the issue you set forth in your letter, and that positive steps are soon initiated within the Society to resolve the issue.

Norma Hopkinson: Although originally I did not favor changing the name of the Society, I have since decided that a change of name would simply avoid a whole set of problems. Some of the problems are based on the possibility of certain legal decisions which will define audiology more narrowly than the Society had originally intended. Other problems are assumed ones, stemming from the lesser than broad concept that led to the initial organization of the society to bring together all specialties interested in audition, without concern for clinical qualifications, research expertise, electroacoustic skills, etc.

Of the possible suggestions that were listed, I would choose: 1) American Auditory Association or 2) American Auditory Society. This choice was made largely by the process of elimination. The words *Ear* and *Hearing* got ruled out because they also seem narrow in concept. Somehow I have prejudice against the word *National*, the reasons for which escape me. If I were beginning all over again without any input I would still favor American Audition Association (or Society), or American Association (Society) for the Study of Audition. These names seem to me to represent more scope than the suggested ones, though I recall, the Committee generally rejected *Audition* as part of a new name.

F.H. Linthicum, Jr.: I personally think the present name of the American Audiology Society should suffice. Changing it at this time so early in its organization might confuse future members. However, if it is the decision of the membership to change the name, I favor the first on the list, i.e., American Hearing Society.

Ralph Naunton: The use of the term "*Audiology*" in our Society's name, is I believe, correct usage; I cannot therefore support a change of name. This belief is not dictated by any wish to diminish the importance of clinical audiology nor to enhance the standing of any other professional group. Nor do I wish to belittle the American Speech and Hearing Association, an organization of which I am proud to be a Member and Fellow.

Raymond Carhart was one of those who introduced the term "*audiology*"; but it would do

little justice to his name were we to insist, that for all time, only those may call themselves audiologists who have taken the course of study and examination at the Masters level prescribed by ASHA. Such a course would also run counter to Davis' contention, made in 1947, that *Audiology* is "...a meeting of varied specialties" and that no one person can be expert in all of the disciplines involved. The American Audiology Society has taken the rational approach in deliberately setting itself up as a forum for all of the professionals with a legitimate interest in audiology, whether they be diagnostic and/or rehabilitative audiologists, physiatrists, biologists, surgeons, psychologists, teachers, speech pathologists, or social workers. To change the name of the Society by excluding the word *Audiology*, would be to deny reality.

Ross J. Roeser: I feel that the question of whether or not members of the American Audiology Society should change the name of the organization is embodied in the more basic question, "What is the present meaning of the term audiologist (note that I refer to audiologist, not *audiology*)?" Members should also be made aware of the possible advantages and disadvantages of changing the name.

I don't think there is any question that the term *audiology* refers to the science of hearing or the study of hearing; in fact, that is the literal meaning of the word. Nor would one question the fact that *otology* is the science dealing with the anatomy, physiology and pathology of the ear. However the question to be asked is whether or

not one who merely studies hearing can be called an audiologist.

If the answer to the above question is yes, then by this reasoning we can also say that one who studies the anatomy, physiology and pathology of the ear is an otologist. Since we don't want to muddy the already murky waters, I would hope that no one outside the medically trained discipline would want to be referred to as an otologist. If the answer is no, then the alternate question becomes what is the meaning of the term audiologist.

Dr. Kenneth Berger recently reviewed the genealogy of the words "*audiology*" and "*audiologist*" in the September-October issue of the *Journal of the American Audiology Society*. As pointed out in this comprehensive review, the term audiologist has had a long and rather controversial history, dating back some forty-five years. During this period the term has been claimed to represent several groups, from those individuals involved strictly in the dispensing and fitting of hearing aids to the individual having specified university training in the audiology curriculum. However, in reviewing the article it is apparent that throughout recent years the term audiologist has come to represent a specific professional entity: the individual who has completed university training at least at the Master's level with a primary curriculum in the science of hearing and its disorders. This is evidenced by the fact that the Society of Hearing Aid Audiologists, as it was once called, changed its name to the National Hearing Aid Society in 1965. Apparently this change occurred to reduce the or-

ganization's identification with the discipline of audiology. In addition, the majority of states now have licensure that limits the use of the term audiologist to those with prescribed training in audiology, eliminating most individuals in the commercial sale of hearing aids from using the term.

Since the term audiologist has come to represent a professional discipline rather than a generic area of interest, I feel that we should change the name. One of the disadvantages of not changing the name is that the multidisciplinary nature of the membership, and thus the purpose of the Society, is not represented in the present name. In addition to the university trained audiologist, we have otolaryngologists, hearing aid dealers, nurses, speech pathologists, and engineers in the Society.

A more serious problem that has emerged throughout the existence of the Society is the connotation that membership in the Society has some relationship to professional qualifications in audiology. Even though our membership requirements are minimum, and membership indicates only that the member has an interest in human hearing, is it not reasonable to assume that all members of a group that has a professional image are members of that profession? For example, if you knew an individual who was a member of the American Medical Society or the American Lawyers Society would you not assume that he or she was a physician or lawyer?

On several occasions the name of the Society has been used to im-

[continued on page 4]

High Frequency Audiometer Survives Plane Crash

Despite serious injury to the airplane and at least 12 of the 85 passengers aboard, a specially made high frequency audiometer safely survived the crash without serious injuries. This is the second serious injury that the audiometer has succeeded in

avoiding in the past three years. Parenthetically, on both of the previous occasions the audiometer was accompanied by Marion Downs, Editor of Corti's Organ, who also happened to survive.

The Interrogatory

[continued from page 3]

ply competence in the area of clinical audiology. Members were warned against using the name of the Society in advertisements. Yet, reprimands had to be given to two members because of violating this principle. The most serious incident in which the Society's name was used to indicate that the members had competence in clinical audiology was during recent FTC testimony. During that testimony it was implied that all members of the Society were audiologists.

The disadvantages that I see in changing the name have only to do with paper work and finding a more suitable name. As Secretary/Treasurer for the Society it was my responsibility to file all of the tax forms, establish IRS accounts, establish proper bank accounts, and a myriad other activities too numerous to mention. In fact, had I known of all of the paper work involved with establishing an American Audiology Society, it is certain I would have been more reluctant to readily accept my post. However, now that we have all of these matters attended to, it will only involve a minor amount of work to change the name if that is what is decided upon by the membership.

If the membership decides to change the name, as it is my hope that they do, the new name must reflect the multidisciplinary nature of the membership. The New Merriam-Webster Pocket Dictionary defines the word "auditory" as, "of relating to hearing or the sense or organs of hearing." My choice, therefore, is the American Auditory Society.

Hiroshi Shimizu: I oppose the change of name of the Society for the following reasons: 1) The term "Audiology" is internationally recognized. 2) So called certified audiologists should be called "Clinical Audiologists" like clinical psychologists and the discipline should hold a title in "Clinical Audiology." 3) It is very unfortunate that the term "audiology" means "clinical audiology" in our country, and therefore that "audiologists" are referred to as those who do only hearing assessment and serve for aural habilitation or rehabilitation. A Statement of Orientation drafted in 1955 defines audiology as the "science of hearing." Audiology is concerned with anatomy and physiology of the auditory system, acoustics, psycho-acoustics, history-pathology of the auditory system, its biochemistry, medical aspects of hearing impairment, audiometry, aural habilitation and rehabilitation. "It is the mobilizing of professional skills to cope with the phenomena of hearing." When an otologist studies a temporal bone, he is working in the field of audiology. It should be one of the missions of the AAS to remind or let the public know what audiology is; it is not just audiometry, by inviting more experts in various disciplines as members under the present name.

Let us not let our Journal become another journal of clinical audiology."

F. Blair Simmons: This is not the first time this argument has come before us and since I was unable to be at the full meeting (nor did I know this was on the agenda) I want to express my own feelings about this "problem." First, whatever a hearing aid dealer decides to do in representing himself is, I think, irrelevant to our Society. I really can't get excited about a proprietary attachment to the word, audiologist. Physicians have the same kinds of problems, osteopathic physicians, chiropractic physicians, etc.

I thought one of the aims of our Society was to further fields of hearing by being beyond that sort of garbage and attempting to work together, not at cross purposes with one or another special interest groups. I can't really see that "real audiologists" have an identity crisis at hand and if the official groups having to do with hearing and speech are going to react to everything a hearing aid dealer does, then we do, indeed, have problems.

In brief, I don't think we ought to change the name of the Society. We have a considerable amount invested in it as it is.

Dix Ward (Past President): The issue seems to be fairly simple. The term "audiologist" evidently means, at least in the USA, a person who is certified by ASHA as having been exposed to certain didactic and practical courses of instruction and who is therefore qualified to measure all aspects of the hearing process. I doubt that there is anything that can be done to modify this situation. The question, then, is whether the term "audiology" is to be only "what audiologists do," which is what the name-changers subscribe to, or whether it is to mean "the body of knowledge concerning the hearing process," which is what its roots imply—and indeed what it meant at the time of the formation of the International Society of Audiology a couple of decades ago.

I oppose changing our name, for several reasons. One is that I refuse to grant that membership in Society X automatically implies that all members are Xists. For example, how many of you are members of the National Geographic Society? Are you therefore a geographer? Another reason is that I get irritated at a country trying to impose its will on the rest of the world—even if only in matters definitional. If I were to support a change here, then consistency would demand that I propose a change in the International Society as well, even though they have had the name far longer than an "audiologist USA" has even existed. The final reason is that I don't like any of the alternatives that have so far been proposed. The only one I would vote for would be the "American Association for the Scientific Study of the Audi-

tory Process", which clearly states our true objectives but is so long that I doubt that others would support it.

Laura Ann Wilber: Although at one time it was strongly believed that conceptually audiology was a discipline which involved many aspects of hearing and was theoretically primarily concerned with the study of hearing, over the years this rather limited academic interpretation has become less wholeheartedly accepted. People who are not really concerned with the study of hearing, but only in one limited area of contact with hearing impaired persons have chosen to call themselves audiologists and some people have used membership in associations such as ours, that contain the name audiology in its title, to call themselves audiologists. They have said that by virtue of being members of the Society they should be considered audiologists and, therefore, could perform all functions carried out by any audiologist. As one who practices audiology in a clinic, participates in audiological research, and continues to study the problems of hearing and hearing assessment, I have not felt that that view was appropriate.

I have seen how State Governments can become confused over interpretation of the word audiologist and can be led to believe that anyone who has ever used a tuning fork, who has ever pushed a button on a screening audiometer, or even who might never have caused sounds to be emitted from audiometers for the purpose of assessing hearing might be the same as one who had full knowledge of and facility with many types of evaluation procedure.

Just as I doubt seriously that physicians would wish to join an organization called a Society of Doctors, and would not want such a society to speak for them, since doctors could encompass persons with Ph.D.'s, Ed.D.'s, LL.D.'s, as well as M.D.'s, so do I also have doubts about belonging to a society which calls itself an audiology society, but which has persons who are not versed in the many aspects of audiology as it functions in clinics, in academia, and in research.

Although I sincerely hope that at some future time the name of our society will no longer be an issue, at this point in time I feel it is. Therefore I strongly urge that we change the name of our society from American Audiology Society, to American Auditory Society.

Editorial

(Cont'd from page 2)

States remind me of the New Yorker's view of the U.S. Isn't it rather provincial to hold the view that we (U.S.) should restrict the meaning of the word when the rest of the world has accepted and promoted its very broad definition? Consider, a moment, the words otology and audiology. Oto refers to the ear and audio refers to hearing. Audio comes from audire (to hear). These words then have two distinct meanings. Since otology refers to the ear in toto and hearing is then subsumed under the ear it would appear that audiology should be subsumed as the part of otology that deals with hearing or the function of the ear.

Consequently there should be no confusion between an otologist and an audiologist. But what do we do about the hearing researcher who studies hearing and the clinician who studies hearing to determine the presence of pathology? What of the anatomist who studies the architecture of the ear or the pathologist who studies abnormalities in this architecture?

In my early fantasies about a society my principle thoughts were directed toward an organization that would produce cross fertilization of thought applied toward integrating the broad multidisciplinary nature of audiology as defined by those who shared in conceiving and birthing the discipline called "audiology."

It is apparent from some of the responses Corti's Organ has received that my attempt to keep audiology at the high level originally intended by its forefathers has not been well received. Consequently, although I feel a name change is wrong, I shall bow to Humpty Dumpty, (in this case a membership vote), if it decides that audiology should be restrict-

ed to include only those trained to measure and evaluate hearing for clinical purposes.

Aram Gerber

Gerber

[Continued from page 1]

tric audiology-speech pathology. Susan Gray presented a paper on the preschool screening of speech, language and hearing. Irving Shapiro presented a paper concerning his experiences with CROS hearing aids on children. Charles Croft presented a paper on conductive hearing loss in patients with velopharyngeal insufficiency. Marion Downs presented a paper on the educational and social implications of conductive hearing loss. Maurice Mendell, Sanford Gerber, and Don Hood presented a panel discussion on central audiometry. The November papers in audiology-speech pathology included a presentation by Fred Bess concerning tone delayed auditory feedback in young children, a paper by Mary Pannbacker, on indications and contraindications for speech therapy in cleft palate, a paper presented by Daniel M. Schwab on the use of Politzer technique for treating middle ear atelectasis and serous otitis media in children and a paper by Quinn C. Beery, on Eustachian tube ventilatory function testing in children. The convention was held at noon on November 18th.

Since all of the attendees spent so much of their time enjoying the world renowned New Orleans cuisine, all were certain to come home overweight.

Next year's convention of the Society will be in Chicago.

[Continued on page 6]

New Name for AAS?

[continued from page 1]

approved a resolution indicating their preference that ASHA be the official organization of professionally trained audiologists. The Task Force approved the following resolution:

"Because of the need to provide a singular and unified thrust in matters on the national level which have relevance to the future provision of quality services to the hearing impaired, the Audiology Task Force feels that the American Speech and Hearing Association should be the sole national organization responsible for the maintenance of those legal and governmental activities which serve to clarify and define the roles and responsibilities of the professional audiologist."

Proponents of the AAS name change argue that if the stated

aims of AAS were to "increase knowledge of audiological and promote the science of audiology" there would be no question about the AAS name. However, nowhere are the terms "audiology" or "hearing tests" to be found in the AAS constitution—except in the Society name! The By-Laws of the organization state the purpose is: "to increase knowledge of human hearing, promote correction of hearing and habilitation and rehabilitation of the hearing impaired individual and to end it shall co-ordinate and disseminate information, particularly through the holding of regular meetings, and the publication of reports by members."

The current AAS membership is about 900 members of which approximately 70 per cent are audiologists by training.

Jerry L. Nor...

Article and Book Reviews

"Acoustic Impedance & Admittance—The Measurement of Middle Ear Function"

Alan S. Feldman and Laura A. Wilber, Eds. Baltimore: The Williams and Wilkins Company, 383 pgs., 1976, approximately \$24.00.

The intent of this new textbook is to provide fundamental information about acoustic impedance measurement for the beginner; however, the experienced impedance user also will find it extremely useful to have all this information available in one book. Feldman and Wilber have gathered a broad spectrum of contributors from the United States and Europe to write on basic measurement techniques and advanced mathematical considerations of impedance and admittance.

Feldman and Wilber contributed five of the fourteen chapters including the Introduction, Anatomy and Physiology of the Middle Ear, Tympanometry, Acoustic Reflex Measurement, and the Middle Ear Battery. Shallop prepared an excellent Historical Development chapter; Lamb and Dunkel wrote on Impedance Measurement with Children; medically related chapters include Eustachian Tube Evaluation by Holmquist and Pathologies and Middle Ear Function by Terkildsen; and excellent discussion is included of the Dynamic Characteristics of the Intra-Aural Muscle Reflex by Erick Borg; Djupesland is included with a thorough discussion of Non-acoustic Reflex Measurement; more technical chapters by Zwislocki - The Acoustic Middle Ear Function, and Van Camp and Cretin discuss Principles of Acoustic Impedance and Admittance; an interesting chapter on applications of impedance measurement to areas of speech pathology by McCall completes the text. The editors also included two appendices, one on equipment calibration standards under preparation by an ANSI Working Group and one list of names and addresses of impedance meter manufacturers.

The Williams and Wilkins Company has done an excellent job in establishing an easily readable format for the text. I do feel that some of the text figures are less than expected. For example, Feldman's tympanograms in Chapter 6 are of an infinite variety of style and reproduction and Wilber's middle ear anatomy drawings in Chapter 3 could have been better.

The strength of the text is reflected in the editor's attempts to bring together the complex worlds of impedance and admittance. Clinically oriented readers should gain a great deal of understanding about mhos,

ohms, cubic centimeters of compliance, and, of course, impedance.

J.L.N.

"Hearing Disorders"
Little, Brown and Co., N.Y.
\$12.50.

EDITOR: Jerry L. Northern
REVIEWER:
Don W. Worthington

According to the preface of this book it is apparent that the editor has made an attempt to put together a group of tutorial essays on the state of the art with regard to the current status of hearing impairment. In contrast, most other books on this subject have presented a summary of research studies or a review of clinical procedures. The editor states that this book was put together to provide relevant information from a wide variety of specialists on "the current status of basic auditory science and the clinical arts." The text is broken down into five separate parts: Part I describes the clinical evaluation of hearing; Part II discusses the hearing process; Part III discusses the medical aspects of hearing loss; Part IV reviews otologic-audiologic habilitation and rehabilitation; and Part V discusses Future Directions. This review will attempt to provide a brief summary of each major section and to highlight the contributions offered by the authors.

The Clinical Evaluation of Hearing

In general, the five major chapters in this section provide an excellent overview of the clinical evaluation of the patient with hearing impairment and/or vestibular problems. Three of the five chapters are extremely easy to follow and combine a useful review of the "basics" as well as an emphasis of the trends in the clinical evaluation. Dr. Northern's chapter on Impedance Audiometry provides an excellent overview of the comprehensive and significant role that impedance audiometry has come to play. In this reviewer's mind, Dr. Northern maintains an excellent balance between theory, historical background and present clinical interpretation of impedance results.

Dr. Feldman's chapter on diagnostic audiology proves an excellent synopsis of how the various audiological tests can be subdivided into categories for attempting to specify the site of lesion. Dr. Feldman has highlighted those site-of-lesion tests which have presently been shown to have the highest predictability for time invested.

Dr. Norris' chapter on ENG is in a logical sequential manner and gives a brief, but com-

prehensive overview of the area of electronystagmography. This chapter would be particularly good for medical students and residents who do not have time or want to take time to get more deeply involved in the evaluation of the vertiginous patient.

In Part I there are two chapters that this reviewer found to be disappointing. The first is the chapter on otologic hearing examination by Dr. Sheehy and the other is the chapter on the audiologic evaluation by Dr. Keith. A reading of Sheehy's chapter would tend to make one believe that the only information the otologists can add to the evaluation of bearing is that information provided by tuning forks. His description of the tuning fork tests and their interpretation is excellent. However, in my opinion he has emphasized this area to the exclusion of other important otologic aspects of the hearing examination. Dr. Keith's chapter on the audiologic evaluation attempts to present a number of rather complicated and difficult-to-understand concepts, such as intra-aural attenuation, the occlusion effect, and the proper utilization of masking. In his attempt to cover these areas and to keep his discussion brief he has provided the situation where a little information can be dangerous. I asked several medical residents to read this particular chapter and they found this chapter to be very confusing, especially the description of masking and its application.

II. The Hearing Process

In Part II of this text, the hearing process is broken down and presented in stages. It starts with the physics of sound, then proceeds to cover the anatomy and physiology of the middle ear, inner ear, and central auditory processes. The initial chapter of this section called "Physics of Sound" is excellent as a review. However, it is probably too brief and too condensed for the reader with little or no background in these areas.

Chapter VII, "Mechanisms of the Middle Ear," by Dr. David M. Lipscomb is one of the best-written chapters on middle ear anatomy and physiology that I have ever read. The material is well organized, follows a logical sequence, and is beneficial in helping one to understand the exact nature of the middle ear.

Chapter VIII, "Physiology of the Inner Ear," by Dr. John Ryan and Dr. Peter Dallos again is a well-prepared comprehensive overview. A great deal of complex material is covered, but very briefly, making the chapter a good overview of this area.

Chapter 9 on "Central Auditory Aspects," by Dr. George E. Lynn

and John Gilroy is interesting reading but does not present the same degree of sophistication found in the other chapters in this section. These latter authors do present some interesting case studies, however, and it is unfortunate that the organization of this chapter was not handled more effectively.

III. Medical Aspects of Hearing Loss

Section III is not all-inclusive with respect to etiology of hearing loss, but certainly presents some very pertinent facts with regard to a significant variety of the potential causes of hearing loss. I was particularly impressed with the chapter on ototoxicity by Dr. Bergstrom and Ms. Patricia Thompson. The chapter not only provides a complete review of the effects of ototoxic drugs on the body systems, but also presents information regarding the type of hearing loss one might expect. The other chapters in this section provide an excellent review with regard to the etiological factors that are covered. These chapters should be read and reviewed carefully by all specialists associated with hearing impairment and the hearing impaired.

IV. Habilitation and Rehabilitation

Upon reading and re-reading this section on Habilitation and Rehabilitation, it continues to be evident that there is indeed a paucity or lack of information with regard to aural rehabilitation. Please do not misunderstand, the information that is presented in this section by all the authors is pertinent and well done. However, it is difficult to report on an area where little is known or practiced. The chapter by Marion Downs is designed to highlight the effect a fluctuating hearing loss caused by otitis media can have on the overall development of a child, specifically receptive language development. Hopefully, the medical practitioners, pediatricians and otolaryngologists will read this chapter carefully and note the key issues which are described and discussed. Dr. Stewart has highlighted the role the various professionals should play in the care and management of the hearing impaired child. If each of the specialists involved with the auditorially handicapped child would fulfill his role as described in this chapter, we could soon revolutionize the child's medical care and education. Dr. Binnie's chapter on Relevant Aural Rehabilitation suggested that professionals, specifically audiologists, should include more definitive measures in developing a complete program in

aural rehabilitation. Some of the measures he suggests are the utilization of auditory and auditory-visual profiles, the use of distinctive feature analysis, and the establishment of a lip-reading profile. At the present time there are probably less than a handful of centers in this country that are utilizing any of these techniques in helping to outline or define an aural rehabilitation program.

Dr. Teter's chapter on Clinical Considerations of Hearing Aids presents first a good basic overview of hearing aid terminology and second, a description of the various types of hearing aids. Certain portions of this chapter reflect his personal biases, as demonstrated by his statements regarding the use of in-the-ear hearing aids and hearing aids for children. I should point out that Dr. Teter emphasizes one extremely important point. That is, **more information rather than less is required when fitting hearing aids on children.**

V. Future Directions

Of all the major sections of this book, the section dealing with future directions is probably the least impressive. There are some strong points, however, e.g., Dr. Simmons presents an excellent overview of the potential that acupuncture holds for the possible treatment of hearing loss. Dr. Vernon, et al. and Dr's. Brackmann and House do an excellent job in reviewing the areas of implantable hearing aids and direct stimulation of the auditory nerve. In short, these chapters present excellent overviews of what has been done in the past with regard to their specific areas, and all three indicate the need for further work in the future. This section seems to be moving along extremely well until one reaches the concluding chapter in the text, the chapter entitled, "The Future Research Needs of Audiology," by Dr. J. Donald Harris. Suddenly the theme of future directions seems to come to a standstill. Dr. Harris' chapter would best be titled, "A Review of the State of the Art" rather than "The Future Research Needs of Audiology."

Summary

Dr. Northern has successfully met his goal of collecting relevant information from a wide variety of specialists on the current status of basic auditory science and the clinical arts. This text does indeed provide a comprehensive review of clinical evaluation, treatment, and care. If there is any area that appears particularly weak, it is the area of exploring future considerations.

Article and Book Reviews

[Continued from page 5]

ations. The only areas of major omission which are evident are discussions of electrocochleography and brain stem audiometry. These two major topics are mentioned in one or two locations in the text but never discussed.

I highly recommend this book as a text for all ENT and pediatric residents. I suggest that it would contain pertinent information which could easily be reviewed prior to their taking professional board examinations. I further suggest it as an excellent review source for all audiologists, and in fact, if I were teaching a course in medical audiology, I would certainly use a major portion of this text as reference material.

"Of Acceptable Risk - Science and the Determination of Safety"

William W. Lowrance.
Published by William Kaufman, Inc., Los Altos, Calif., 1976.

This book should be mandatory home work for anyone connected with OSHA, and particularly for those making regulations for noise control. The author explores the nature and measurement of health hazards, and in the process defines the underlying concept of safety itself. Although he emphasizes the contributions of scientists and technicians, he also considers the general features of the social context within which safety decisions are made.

Why is that one group of eminent experts say that exposure to a certain hazard is safe, while another group of authori-

ties, equally reputable, urges that exposure to the same thing should be restricted because it is unsafe? At what points do debates such as that over noise stop being scientific and objective and start being political and subjective? How can anyone gauge the public's willingness to accept risk? Just what sort of a decision making tool is this notion of "safety?"

These are the questions the author addresses himself to, with real examples of current interest to highlight each point. He first defines "safety" as a "judgement of the acceptability of risk", and proceeds to develop the key terms "acceptable" and "risk" in detail. For example, in assessing risk, he lists the reasons for making measurement of a hazard: (1)To define the conditions of exposure; (2)To identify the adverse effects; (3)To relate exposure with effect; (4)To estimate overall risk.

Of these measures, one of the least understood methods turns out to be public opinion of acceptability of the risk. "Public referenda have been applied in only a few instances, mostly where public interest is intense and where people experience the hazard in an immediate, personal way, as with noise. People's subjective rating of noises can be analyzed, as can lawsuits and annoyance complaints. Such analyses can correlate annoyance with factors of socioeconomic status, fear, importance of the noisy activities, perception of fair treatment, and the extent to which the noise can be controlled or reduced".

But even in the public's perceptions of the extent of risk there lie factors that may be infinitely variable. One is that our opinions of what is ac-

ceptable depend on the degree to which we are free to opt for or decline the risk. "We are loathe to let others do unto us what we happily do to ourselves." The array of such variables influencing safety judgements is long and well developed by the author.

In some hazards it is the impossibility of knowing the true nature of the risks that is most upsetting: an "anguishing over uncertainty itself". Such is the case in the opposition to the SST, where the dictum "if in doubt, don't" has prevailed. Whether there are purely technical solutions to such problems remains to be seen, of course. Some problems are attended by great uncertainty or strong political overtones, and become as much a political activity as a scientific one.

One solution is for scientists to convert an "arrogation of wisdom" into a "stewardship of wisdom". First, they can include critical, articulate laymen in their policy-making group. Second, they can place on record their sources of conflict of interest or bias. Third, they can identify which components are scientific facts and which are value judgements. Fourth, they can disclose in detail the bases of their appraisals. Fifth, they can reveal the degree of certainty with which the various parts of the decisions are known; and sixth, they can express their findings in clear terms, free of technical jargon.

These are the kinds of admonitions that all scientists should welcome, whatever their endeavors. An important book, this, to clean some of the cob webs from our over-worked minds.

—M.P.D.

Eleventh Otology-Audiology Vail Workshop Announced

The 11th Colorado Otology-Audiology Workshop promises to uphold the long tradition of combining outstanding scientific teaching sessions, social conviviality and winter fun! Twelve scientific sessions and ten practicum presentations have been scheduled featuring a faculty of 35 speakers.

The theme of the conference is again "The Ear". New faculty participants include Richard Bobbin, and Douglas Webster of the Kresge Hearing Lab. of the South and Louisiana State University Medical Center. Dr. Bobbin has recently uncovered a drug, aminooxyacetic acid, which seems to protect the ear against noise exposure and will speak on the possible biochemical nature of noise-induced hearing loss. Dr. Webster has recently noted brainstem degeneration in animals with contrived conductive hearing loss and will speak on the relationship of peripheral hearing loss to central auditory anatomy. From the medical point of view, Derald Brackmann from the Otologic Foundation in Los Angeles, will speak on electrical response audiometry with acoustic tumor patients as well as an update on the status of cochlear implants. Burton Jaffe, from Temple University in Philadelphia will present material on ENG and Diagnosis in the dizzy patient, and audiologic diagnosis in acoustic tumors. John Shea of Memphis, will be the Workshop Special Guest and present lectures on treatment of fluctuant hearing loss, experience with Proplast in reconstruction of chronic ears, and technique/results of the TORP prosthesis.

Additional new faculty include Bill Rintelmann of the University of Pennsylvania School of Medicine and W. Dix Ward of the

University of Minnesota Medical School. Dr. Rintelmann will speak on the problems of over-amplification with hearing aids, and research with time compressed speech. Dr. Ward's presentation will relate to auditory adaptation and the "safe-noise dose."

Returning faculty members include: Ray Battin, Houston, Texas; LaVonne Bergstrom, University of California at Los Angeles; Charles Berlin, Louisiana State University Medical Center; F. Owen Black, Eye and Ear Hospital, Pittsburgh; Peter Dallos, Northwestern University; Alan Feldman, SUNY Upstate Medical Center at Syracuse; Garth Hemenway, Harbor General Hospital; Lars-Goran Johnsson, University of Michigan Medical School; David Lim, Ohio State University; David Lipscomb, University of Tennessee; Geary McCandless, University of Utah Medical Center; F. Blair Simmons, Stanford Medical School; and Paul Ward, University of California at Los Angeles.

Facts from the Feds

The Bureau of Community Health Services, in a grant to Ohio State University, is convening a select panel in January, 1977 to assess guidance material and develop recommendations relating to Health Services for testing and treating preschool children with hearing impairments. The participants will include state health agencies' representatives as well as experts in

Medicine and Audiology.

The Bureau of Community Health Services has awarded funds to Vanderbilt University (Dr. Earl Hartford) to conduct a national conference on Impedance Audiometry in June, 1977.

by the size of the churches, its beautiful doors, its statues such as the world famous statue of David, in the Gallery of the Academy, sculptured from one solid piece of marble by Michelangelo himself. The statue towers majestically in the presence of six other great statues by the famous sculpture and artist. Among some other sites common to the visitors of the International Congress were the famous Ponte Vecchio Bridge with its many gold shops and pedestrian traffic only, the Uffizi Museum, with one of the most valuable art collections in the world, the famous bronze door by Ghiberti called the "Gate of Paradise" and across the street rises the Duomo, Brunelleschi's immense and daring dome. Another landmark was the great Franciscan Church of Santa Croce, one of the most imposing monuments of Gothic Architecture, with many frescoes by Giotto. Also in the church are the tombs of famous Italians: Michelangelo, Machiavelli, Galileo, Rossini, Dante, Leonardo de Vinci, and others. A leather

school was located within Santa Croce where young men would make and sell their famous leather purses, wallets, and memorabilia to the wide-eyed tourists including this member. In short, to know Florence is to love her in spite of her longevity. The XIII International Congress of Audiology could not have selected a more appropriate site for mixing science with culture and not the least of which was street shopping.

Tremmel, Hill Get BHM Awards

Washington, D.C., (November 8, 1976) -- Clarence B. Hill, president of Hill's Hearing Aid Service in Oklahoma City, Oklahoma, and DuWayne Tremmel, president of Better Hearing Aids, Inc., in Marshfield, Wisconsin, have received 1976 Better Hearing Month Achievement Awards from the Better Hearing Institute. The awards were presented by BHI President Joseph C. Lucke at the recent National Hearing Aid Society conference in Chicago.

Lucke commended Hill and Tremmel for their "outstanding information and education efforts on behalf of the millions of hearing-impaired Americans during National Better Hearing Month." "Thanks to you and others like you," he added, "this year's campaign was one of the most successful in history."

Also honored for their Better Hearing Month efforts were runners-up Louise Olsen of Arrowhead Hearing Aid Center, Duluth, Minnesota, and William Syers Jr. of Davenport Hearing Aid Center, Inc., Davenport, Iowa.

The Better Hearing Institute, Washington, D.C. is a nonprofit educational organization dedicated to informing the hearing impaired, their families and friends, and the general public about hearing loss and available hearing help. Better Hearing Achievement Awards are presented annually by the Institute to NHAS Public Affairs Committee members who are most active and effective during Better Hearing Month.

School Receives Grant From Hearing Aid Foundation

A grant of \$1000 was made this year to St. Rita's School for the Deaf, Cincinnati, Ohio, by the Hearing Aid Foundation. St. Rita's School for the Deaf is a long established school that has provided excellent help to deaf and severely hearing impaired children. Hearing Aid Foundation is a non-profit organization providing grants to charitable organizations dedicated to aiding the hearing impaired. Its grants are made possible by contributions from hearing aid specialists, manufacturers and suppliers and by concerned individuals.

The photograph shows Father Klenke, director of St. Rita's school, receiving a check from Stanley K. Foster (right), President of the Ohio Hearing Aid Dealers Association, who made the presentation of the grant on behalf of the Hearing Aid Foundation.

Father Klenke and Stanley K. Foster (Right)

Calendar of Events

1977

FEBRUARY

20-23 Ear Surgery Course, J. Brown Farrior, M.D., Tampa, Fla.

MARCH

5-12 Medical Audiology Workshop, Vail, Colorado. For Information write to: Box B210, 4200 E. 9th Avenue, Denver, Colorado 80262.

13-19 11th World Congress of Oto-Rhino-Laryngology, Buenos Aires, Argentina. For information write: Dr. Alfredo Cordero, Secy., Av. Rocque S. Pena 1110-2° Piso, Buenos Aires.

14-17 NOISEXPO '77, The National Noise and Vibration Control Conference and Exhibition, Holiday Inn, O'Hare/Kennedy Chicago. Technical papers, films and other presentations are solicited: NOISEXPO '77, 27101 E. Oviatt Road, Bay Village, Ohio 44140.

APRIL

14-16 16th Annual Electronystagmography Course, New Orleans. Contact Wallace Rubin, M.D., 3333 Kingman Street, Metairie, Louisiana 70002.

MAY

9-11 1977 IEEE International Conference on Acoustics, Speech Signal Processing, Hartford, Connecticut. Write to Harvey Silverman, IBM-T.J. Watson Research Center, P.O. Box 218, Yorktown Heights, New York 10598.

25-29 White House Conference on Handicapped Individuals, Washington Hilton Hotel, Washington, D.C. Write to: Jack F. Smith, White House Conference on Handicapped Individuals, 1832 M Street, W., Suite 801, Washington, D.C. 20036

JUNE

7-10 Acoustical Society of America, State College, Pennsylvania.

20-22 National Symposium on Impedance Screening for Children, Vanderbilt University, Nashville, Tenn. Contact Earl Harford, Division of Hearing and Speech Sciences, Vanderbilt University, Nashville, Tenn., 37212. (See below for announcement).

JULY

4-9 Ninth International Congress on Acoustics, Madrid, Spain.

AUGUST

15-18 Symposium of the International Electric Response Audiometry Study Group, Hebrew University, Jerusalem, Israel. For information write to: Prof. H. Sohmer, ERA Organizing Committee, Medical School, P.O.B. 1172, Jerusalem, Israel.

OCTOBER

31-Nov. 2 Evoked Electrical Activity in the Auditory Nervous System, Chicago, Ill. Write to: Ralph Naunton, M.D., Dept. Otolaryngology, University of Chicago, Chicago, Ill. (See page 9 for program.)

NOVEMBER

18-21 American Speech and Hearing Association, Chicago, Illinois.

DECEMBER

12 American Audiology Society, Miami Beach, Florida

13-16 Acoustical Society of America Meeting, Miami Beach, Florida.

REQUEST FOR 1977 DUES

—SECOND NOTICE—

IF YOU HAVE NOT PAID 1977 MEMBERSHIP

DUES, PLEASE DO SO IMMEDIATELY.

[\$20.00 dues; \$13.00 is for the journal, and \$7.00 is for
membership in the Society]

Call for Papers

VANDERBILT

A national Symposium on Impedance Screening for Children: Current Status for Detection of Middle Ear Disease will be held at Vanderbilt University, Nashville, TN, June 20-22, 1977. The Program Committee is inviting abstracts of investigations on this subject. Those accepted for presentation will have expenses paid. Submit 1 to 2 page abstract on unpublished and/or current research to: Dr. Earl Harford, Division of Hearing and Speech Sciences; School of Medicine; Vanderbilt University; Nashville, Tennessee 37212. Deadline is February 21, 1977, for receipt of abstracts.

Naunton Announces International Symposium

An exciting conference is being scheduled at the University of Chicago by Ralph Naunton, head of the otolaryngology department. The full projected program will study in depth the possibilities of stimulating and measuring the auditory nervous system electrically, as follows:

EVOKED ELECTRICAL ACTIVITY IN THE AUDITORY NERVOUS SYSTEM

A University of Chicago Symposium

To be held at the Center for Continuing Education

University of Chicago, Chicago, Illinois, U.S.A.

October 31-November 2, 1977

Monday, A.M.

Welcoming Remarks

Anatomy Chairman: R. Lorente de No'

1. Ultrastructure of the Cochlear Duct C.A. Smith
2. Afferent Innervation H. Spöndlin
3. Efferent Innervation W.B. Warr

Coffee

Physiology Chairman: J.M. Goldberg

4. Electrical Equivalents to the Bekesy Traveling Wave in the Mammalian Cochlea D.H. Eldredge
2. Hair Cells (Round Table Discussion) J.M. Goldberg (Chairman), M.L. Bennett, P. Dallos, (J.Fex), A. Flock, T.F. Weiss.

Lunch

Monday, P.M.

Physiology Continued

5. Hair Cells (Round Table Discussion Continued)
6. Cochlear Electrophysiology P. Dallos

Coffee

7. Facts and Illusions Related to the Methods for Recording Whole-Nerve Action Potentials D.H. Eldredge
8. Auditory Nerve Responses N.Y.S. Kiang

Adjourn

Monday Evening

Electrococleography [I] Chairman: G. Salomon

9. Recording Techniques S. Zerlin
10. Stimulus Response Relations J.J. Eggermont
11. Behavioral Threshold Comparisons R.F. Naunton

Tuesday, A.M.

Electrococleography [II] Chairman: F.B. Simmons

12. Adult Clinical Diagnosis I. H.A. Beagley
13. Adult Clinical Diagnosis II. J.M. Aran
14. CM in Clinical Diagnosis S. Zerlin
15. ECoG Diagnosis (Round Table) J.M. Aran, H.A. Beagley, J.J. Eggermont, R.F. Naunton, S. Zerlin.

Coffee

Inner Ear Prostheses Chairman: N.Y.S. Kiang

16. Significance of Inner Ear Pathology J.R. Lindsay
17. Instrumentation F.B. Simmons
18. Psychoacoustic Considerations R.C. Bilger
19. Value of Implants F.O. Black

Lunch

Tuesday, P.M.

Brainstem Chairman: J.E. Rose

20. Auditory Fibers and Primary Cochlear Nuclei E.S. Kane
21. Central Auditory Pathways (J.M. Harrison)
22. Physiology of Brainstem Auditory Centers (C. Tsuchitany)

Coffee

23. Basic and Clinical Aspects of Brainstem Recording in Humans (Round Table) H. Davis (Chairman), R. Galambos, G.M. Gerken, A. Starr, K. Terkildsen, A.R. D. Thornton

Adjourn

Wednesday, A.M.

Cortex Chairman: R.A. Butler

24. Anatomy I.T. Diamond
25. Physiology J. Brugge
26. Distribution on the Scalp of Sound-Evoked Responses W. Goff
27. Clinical Aspects of Evoked Responses G. Salomon
28. Evoked Responses in Children of Uncertain Diagnosis. I. Rapin and M.M. Cohen

ANSI Specs. Defined

SUMMARY

American National Standard for
Specification of Hearing Aid
Characteristics

Courtesy of Technical Marketing
Group

Zenith Hearing Instrument Corp.

Definition of Some Terms:

Saturation sound pressure level for 90dB input sound pressure level. The sound pressure level developed in a 2 cm³ earphone coupler when the input sound pressure level at the microphone sound entrance on the hearing aid is 90dB SPL with the gain control of the hearing aid full-on. The abbreviation for this term is SSPL90.

High-frequency-average saturation sound pressure level. The average of 1000, 1600 and 2500Hz values of SSPL90. The abbreviation for the term is HF-average SSPL90.

Note: The prefix "HF" is used to differentiate this quantity from the "output" which uses 500, 1000 and 2000Hz for averaging.

High frequency-average full-on gain. The average of the 1000, 1600 and 2500Hz values of full-on gain. The abbreviation for the term is HF-average full-on gain.

Reference test gain control position. The setting of the hearing aid gain control so that the average of the earphone coupler sound pressure levels at 1000, 1600 and 2500Hz, with a pure-tone input sound pressure level of 60dB is 17 dB plus 1dB less than the HF-average SSPL90, or, if the gain available will not permit this, and for AVC aids, the full-on gain control position of the hearing aid.

Recommended Measurements

SSPL90 curve - With the gain control full-on and with basic settings of controls, record or otherwise develop a curve of coupler sound pressure level versus frequency over the range 200-5000Hz, using a constant input sound pressure level of 90dB.

HF-average SSPL90. Average the 1000, 1600 and 2500Hz SSPL90 values.

Full-on gain curve. Full-on gain shall be measured with the gain control set to its full-on position and with a sinusoidal input sound pressure level of 60dB, or, if necessary to maintain linear input-output conditions, with an input sound pressure level of 50dB. For AGC aids, the input sound pressure level shall be 50dB.

HF-average full-on gain. Average the 1000, 1600 and 2500Hz full-on gain values.

Frequency response curve. With the gain control in the reference test position, and with

an input sound pressure level of 60dB, record or otherwise develop the frequency response curve over the range 200-5000Hz or a lesser range determined by limits 20dB below the average of the 1000, 1600 and 2500Hz response levels. For AGC aids and input sound pressure level of 50dB is to be employed.

Harmonic distortion. With the gain control in the reference test position and with an input sound pressure level of 70dB, measure and record the total harmonic distortion in the coupler output for input frequencies of 500, 800 and 1600Hz.

In the event the response curve rises 12dB or more between any distortion test frequency and its second harmonic, distortion tests at that test frequency may be omitted.

Equivalent input noise level (L). With the gain control in the test reference position determine the average of the coupler sound pressure levels at 1000, 1600, and 2500 Hz for an input sound pressure level of 60dB. (Lave). Remove the acoustic signal and record the sound pressure level in the coupler caused by inherent noise (L2). Then Ln equals L2 - (Lave - 60) dB.

Battery current. With the gain control in the reference test position, measure the battery current with a pure-tone 1000Hz input signal at a sound pressure level of 65dB.

Coupler sound pressure level with induction coil. With the gain control full-on and the hearing aid set to the "T" (telephone input) Mode, the hearing aid is placed in an alternating magnetic field having a frequency of 1000 Hz and a magnetic field strength of 10m A/m and oriented to produce the greatest coupler sound pressure level.

Automatic gain control hearing aids. The following tests apply to AGC aids:

Input-output characteristics. Using a pure tone test frequency of 2000 Hz, measure and plot the coupler sound pressure level for input sound pressure levels from 50 to 90dB, in 10dB steps.

Dynamic AGC characteristics. With the gain control full-on and using a square wave modulated pure tone input signal of 2000 Hz determine the attack time defined as the time between an abrupt increase from 55 to 80 dB and the point where the output has stabilized to within 2dB of the steady state value for the 80dB input. The release time is defined as the interval between the abrupt drop from 80 to 55 dB and the point where the output has stabilized to within 2dB of the steady state value for the 55dB input.

Siemens Hearing Instruments "Five Point Consumer Security Blanket"

Wrap-around coverage for you
and your clients.

It makes sense.
When you have the best hearing aids,
you're entitled to the best package of after-sale
services. And that's exactly what you get with
every Siemens hearing aid.

Here's how it works:
First there's a warranty that runs **two full years**—
that's double the length of most warranties in
the industry. And there's a 45-day, no-questions
asked, change-your-mind return policy. Plus
same-day servicing on most repairs at our
national service center.

To go with all that, there's a 5-year performance
guarantee that every Siemens Hearing aid
will continue to live up to its initial specs, year
after year. We'll even send along a "B&K" tape
upon request.

And finally, there's a low cost, 2-year
insurance plan that protects your clients against
most types of accidental loss or damage—a
must for parents of hard-of-hearing children.

That's just a bare outline of Siemens' new
Consumer Security Blanket Program. For
complete details, give us a call toll-free
(800)631-7965 or drop us a line.
Siemens Hearing Instruments, Inc.,
685 Liberty Ave., Union, New Jersey 07083.

SIEMENS

Tracoustics Honors . . .

Brian E. Walden, Ph.D., currently a Captain in the Medical Service Corps of the U.S. Army, is the recipient of the 1976 Outstanding Military Audiologist award. Tracoustics, Inc. of Austin, Texas provided a beautiful bronze award to the Military Audiology-Speech Pathology Society (MASPS) to honor their outstanding member. Charlie Anderson, President of Tracoustics, Inc. indicated that the award will become an annual event.

Dr. Walden was selected for his commitment to audiologic research for the benefit of hearing handicapped military personnel. The award was presented by Mr. Don Musick of Tracoustics, Inc. Major Roy Sedge, Ph.D., current President of the Military Audiology-Speech Pathology Society, summarized Dr. Walden's contributions as follows:

"Over the past five years, CPT Brian Walden, serving as a researcher, clinician and military advisor, provided the single most important document to foster the

Army hearing conservation program entitled "The Prevalence of Hearing Loss Within Selected U.S. Army Branches." In addition, CPT Walden designed the largest clinical auditory research laboratory within the U.S. Army located at Walter Reed Army Medical Center. Research in this laboratory has resulted in a new modular aural rehabilitation program in operation at the U.S. Army Audiology and Speech Pathology Center in the Forest Glen section of WRAMC. Dr. Walden is currently involved in numerous research efforts including the development of a speech discrimination test to predict communication difficulties from military noise-induced hearing loss patients."

CPT Brian Walden is currently assigned to Walter Reed Army Medical Center as Auditory Research Director. He will soon complete his active duty obligation, but remain in his current position, and continue his efforts, as a civilian.

Outstanding Military Audiologist Award, 1976

BHI Speakers Bureau

WASHINGTON* D.C.* (November 1, 1976)— "Silence is Lonely," a moving and informative new slide/cassette presentation now available from the Better Hearing Institute, focuses on hearing loss in the golden years. The presentation, for showing by hearing field representatives to local civic, social, and fraternal organizations, will help to provide encouraging hearing help information to those who need it. It also can be used as a model from which to develop customized speakers bureau productions.

Utilizing a case history approach, "Silence is Lonely" explores the personal and emotional problems associated with hearing handicaps and emphasizes all types of hearing help—medical, surgical, and amplification. Featured in the presentation is actress Nanette Fabray, who overcame her own hearing disorder. Ms. Fabray encourages senior Americans with hearing loss to admit they have a hearing problem and to seek help. In

addition, she discusses the magnitude of hearing impairments, prevention and warning signs. BHI Advisory Board Chairman and ear surgeon, Dr. Charles Gross also appears in the presentation to briefly explain the hearing process and types and causes of hearing disorders.

"Silence is Lonely" is self-contained for easy usage. Slides are advanced automatically by a tape with inaudible magnetic impulses or they can be manually projected by following script cues. Each set includes a 15 minute cassette, 80 slides in a carousel tray, a slide-keyed script, and helpful suggestions and how-to instructions. Order from BHI, 1430 K Street, N.W., Suite 200, Washington, D.C. 20005. Cost: \$49.95.

The Better Hearing Institute, Washington, D.C., is a non-profit educational organization dedicated to informing the hearing impaired, their families and friends, and the general public about hearing loss and available hearing help.

CORTI'S ORGAN

(Audionews)

The Official House Organ of the American Audiology Society

Vol. 2, No. 2

April, 1977

Proposal for By-Law Change-of-Name Finalized- 'American Audiology Society' Wins

The results of the balloting on a possible name change for AAS are in. A majority of the members voting favored a revision in the name. The votes were as follows:

1. Do NOT favor name change 62;
2. DO favor name change 82;
- 2 ... American Hearing Society

VOTES

1. ... National Association for Hearing;
2. ... American Association for Hearing;
1. ... American Hearing Association;
3. ... American Auditory Association;
3. ... National Auditory Society;
6. ... American Association for Study of Hearing;
2. ... American Audition Society
2. American Society of Audition

63. ... American Auditory Society
14. ... Other. (Several suggested

"American Otology Society").

In view of this mandate, we submit to the membership the following proposal for a By-Law change. BE IT PROPOSED:

THAT CHAPTER I, ARTICLE I, WHICH PRESENTLY READS, "AN AMERICAN AUDIOLOGY SOCIETY SHALL BE CONSTITUTED UNDER THIS NAME" BE CHANGED TO READ: "THE NAME OF THIS SOCIETY SHALL BE THE AMERICAN AUDITORY SOCIETY."

The constitution provides that a proposed By-Law change must be submitted to the membership six months before the annual meeting at which the members vote on the proposal. Seventy percent of

the members must be present or respond to a mail ballot at that time, and a three-quarters vote is necessary to amend.

A First— Union Provides Hearing Aids

For the first time in history, a union has extended its health coverage to provide hearing aids for its members. United Auto Workers has received commitments from the Ford Motor Co., Chrysler, General Motors and Ford/Canada to provide hearing aids for all those covered under the health care program. Coverage includes retirees, dependents and surviving spouses, and active employees with one year of seniority plus their dependents.

Payments will be made to "participating providers" only, including hearing aid dealers, audiologists and physicians who qualify as participating providers.

The initial prescription recommending a hearing evaluation must be paid for by the member. A "medical hearing specialist" (Board certified otolaryngologist), must make this recommendation. Once this is done, a participating doctor or audiologist conducts an audiometric test and prescribes a specific model of hearing aid. These services are paid for by the plan.

The plan also pays for the filling of the hearing aid prescription by a hearing aid dealer who is a participant. Follow-up visits to doctor or audiologist are pro-

Call For Papers Pomerantz Outlines 1977 AAS Meeting

Miami Beach will be the exciting setting for the 1977 annual meeting of the AAS. Harris Pomerantz, program chairman, is planning scientific presentations on **The Effects of Pressure Changes in The Auditory System**. In addition he has planned for members to make personal investigations on pressure changes under water.

Members are requested to submit abstracts of papers on the general theme **EFFECTS OF PRESSURE CHANGES IN THE AUDITORY SYSTEM**. Papers will be of 10 to 12 minutes duration and will be presented during the morning session of the annual meeting. The Raymond Carhart Memorial Lecture will be presented in the afternoon session.

Papers relating to diving and high altitude auditory system physiology are particularly desired for presentation, but papers on other topics are also requested.

During the weekend preceding

the annual meeting some of the effects of increased pressure on the auditory system will be investigated during a diving trip to John Pennkamp Reep State Park, a Florida underwater state park encompassing a magnificent living coral reef off Key Largo, Florida.

It should be noted that the annual AAS meeting on Monday 12 December, precedes the 13-16 December Tuesday-Friday meeting of the Acoustical Society of American at the Carillon Hotel.

Transportation for the diving trip will be arranged. The executive committee meeting will be scheduled to avoid conflict with the reef trip.

Abstracts of contributed papers following the Acoustical Society of American format, should be submitted to Harris I. Pomerantz, M.S., Section of Otolaryngology, University of South Florida College of Medicine, 13000 No. 30th Street, Tampa, Florida 33612.

A Special Report To Corti's Organ on the Evaluation of Implanted Auditory Prosthesis Page 12

vided to determine the effectiveness of the aid. Coverage is provided for hearing aids every 36 months.

The new benefits will be effective October 1, 1977.

Among the victims of the Canary Island plane disaster were the mother and father of our president-elect, Blair Simmons. The members of the Society send their deepest condolences to Blair.

News About Members

Merle Lawrence, director of Kresge Hearing Research Institute, has been appointed a member of the National Advisory Neurological and Communication Disorders and Stroke Council of the National Institutes of Health.

Dennis L. Landesman was named one of California's Five Outstanding Young Men for 1976. The award was presented to him for his activities in establishing a free summer camp for 300 deaf children and for a hearing aid loaner bank for needy deaf children.

BOYS TOWN

The staff of Boys Town Institute has finally moved into its new quarters and begins an exciting clinical career with 36 staff members.

The directors of the Institute are: Patrick E. Brookhouser, M.D., Director, Boys Town Institute; Noel D. Matkin, Ph.D., Director, Language and Learning Center; Don W. Worthington, Ph.D., Director, Audiology and Speech Pathology; Charles S. Watson, Ph.D., Director Human

Communications Research Laboratories; Jack R. McCullough, M.P.A., Director, Administration and Support Services.

Corti's Organ takes this opportunity to wish a long life and success to the Institute and its directors.

Congratulations can be sent to:

The Boys Town Institute
Father Flanagan's Boy's Home
Boys Town, Nebraska 68010.

Yanick & Ross Plan Instrument Conference

Paul Yanick and Mark Ross have put together a workshop conference on Hearing Instrument Technology Signal Processing June 4-5, 1977 in Clark, New Jersey. Stephen Freifield, M.D., will be one of the featured speakers at the meeting.

The purpose of the workshop is to provide for the demonstration of new procedures and electro-technology, and to provide opportunity for discussions of case histories among group participants. The workshop will include the following topics:

Signal Processing:

A. Test procedures for the measurement of equal loudness pressures;

B. Various electroacoustic adjustments used in processing;

C. Review of actual case histories.

D. Application of the electroacoustic parameters of hearing aid response to the sensorineural ear.

E. Practical experience with signal processing.

The meeting is sponsored by The HEAR Foundation.

Sataloff-Glorig Institutes Announced

Former AAS President Aram Glorig and otologist Joseph Sataloff will again direct the two University of Maine Institutes on Occupational Hearing Loss and Hearing Conservation. These well-known courses have been the most popular of any in the country with physicians and nurses interested in occupational hearing problems.

The 25th annual Institute in Occupational Hearing Loss will be held June 27-July 1, 1977, at the University of Maine at Orono (Bangor). The Institute is designed for industrial physicians, safety engineer, hygienists, otolaryngologists, health management executives and administrative personnel. Designed to permit certification in audiometric proficiency, it awards 27 credits in PRA Category 1 of AMA for physicians. Covers total field of conservation of hearing programs, medico-legal and compensation aspects, and OSHA developments. Lectures and laboratories are combined with practical field trip to couple theory and implementation. Tuition is \$275 and Room and Board is \$25 per day.

The 14th annual Industrial Hearing Conservation Institute is

June 27-June 30, also at the University of Maine. The facilities of the University of Maine provide excellent accommodations for the participants. The institute is concerned with responsibilities of industrial nurses and those actively interested in hearing testing performance and record keeping. Participants eligible for certification by the Council for Accredi-

tation in Occupational Hearing Conservation. It awards 2.6 CEU's by the Maine State Nurses Association. Tuition is \$235 and Room and Board is \$25 per day.

For descriptive brochure and application write or phone: UMO Coordinator, 1721 Pine Street, Philadelphia, PA 19103 - (215) 735-0205.

LETTERS TO THE EDITORS

Dear Editors:

After reading the sensitive reaction of the vision founding prime source, ex-officio comments, as well as present leadership visions, my impression is that the name AAS should be utilized to its fullest original intention.

If the only problem arising, for the name change hysteria, is some kind of a sanction acceptance for the hearing aid dealers who may represent themselves as AUDIOLOGISTS due to the AUDIOLOGY content of the name—ask the hearing aid handler to pledge against the subject designation or to be asked to leave the society.

The time has come when the profession of audiology must define the functions and responsibilities of the handler of hearing instruments; the medical profession has already done this. At this time, you may find a myriad of experience ready to help form this vital hearing health team; that Lloyd S. Bowling, Ed.D., George Washington University, speaks of.

Paul J. Frantell

Dear Editors:

On the matter of name change, we could retain American Audiology Society, limit full membership to "audiologists" and offer associate membership to otologists; or change the name to American Audiology and Otology Society, limit full membership to "audiologists" and "otologists" and offer associate membership to hearing aid dealers; or change to American Audiology, Otology and Hearing Aid Dealers Association with ear mold fabricators as associate members; or....

Adoption of American Auditory Society might be the most acceptable compromise unless we want to face the issue squarely and restrict membership to individuals with academic and scientific credentials entitling them recognition "in Audiology—the science of hearing." This may strike some as arbitrary, but aren't all groups, societies, associations parochial?

—Laszlo Stein

Dear Editors:

Little did Ray Carhart and I realize what controversy there would be when we urged the use of the term AUDIOLOGY. Some of the members of THE AUDIOLOGY SOCIETY will remember my unsuccessful efforts in the 1950s when I insisted on an official definition of AUDIOLOGY; more than the one which was first used in the medical dictionary as "the science of hearing." I tried to get a consensus of what the term should include. At least one joint committee of the two societies most involved worked long hours trying to agree on a proper definition and an indication of the specialty's content. Warnings were then expressed of the possible legal implications of letting the term dangle without proper official definition which could be the basis for all future considerations.

However, time went by and now we have not only the legal hassles in the various state laws, but Uncle Sam himself is breathing on us mightily because of our inter-society controversy. Sometimes I wish the word had never been resurrected from the 1930s, but at the time it did seem to properly indicate a special professional endeavor. And in spite of the perversity of us humans, including me, great service has been rendered to those with hearing defects.

As I contemplate the comments in the current ORGAN OF CORTI, I realize the value of the potent arguments both for name change and no change. All the suggested names will evoke criticism from some quarters, so I humbly suggest that we avoid any controversial name and call ourselves:

THE CARHART SOCIETY
FOR PROGRESS IN HUMAN
HEARING.

Not only will this name avoid more trouble but we will thereby do great honor to the finest AUDIOLOGIST OF US ALL.

—Norton Canfield

[Editor's note: Dr. Canfield's present address is: 49 State Street, Guilford, Conn. 06437]

Editorial

The action of the AAS in proposing a name change represents microcosm of Democracy-in-Action. Everyone in AAS is expressing his opinion freely, without acrimony, but with a lively interest. In fact, the membership has been so pleasant about it all that it's been really fun to work on.

It's quite evident that regardless of what the outcome of the final voting is the result will be accepted with good will by the opposition. It seems to us that this vote is bringing out the strengths of AAS as nothing else could. Despite its disparate beliefs and occupations, the organization is welded together by a firm and loving interest in the auditory phenomena of the ear. No temporary differences of opinion will ever produce a schism in the single-purposed group.

It's nice to belong to this kind of organization—sort of restores one's belief in the rationality of mankind!

—MPD-RJR

Gretchen Syfert stands in front of Seifert Horgerote [hearing aid] dispensary in Nuremberg, Germany. Maybe a long lost relative-in-law?

THE INTERROGATORY

In July of this year an election will be held to replace seven members of the Executive Committee of the American Audiology Society. In this issue of Corti's Organ we have asked each candidate nominated for the office to provide the Membership of the Society with some basic biographic information, and to provide their thoughts regarding the future direction of the Society.

Allen G. Berchowitz, Ph.D., 1959, New York University; Director of Audiological and Speech Services, Manhattan Eye, Ear and Throat Hospital. Address: 39 Gramercy Park, N.Y., N.Y. 10010
The American Audiology Society (my choice as a name change) should focus upon the multidisciplinary sharing of information and research in the field of audition. It should direct itself towards a professional collaboration in the areas of audiology, otology and acoustics. This goal orientation would eliminate the dissension and divisiveness currently arising between the various disciplines.

James R. Curran, MS, 1962, University of Wisconsin; Director, Auditory Research Program; Marco Hearing Instruments, Inc. Minneapolis, Minn.

I am in favor of a name change for the Society, for it appears that presently there is too much room for confusion and misunderstanding regarding our purpose.

In a time, however, when so many decisions are being made by others about all aspects of hearing health care, it is conceivable that pressures may be put on the Society to take official stances concerning various politically sensitive issues. We should, therefore, support a policy which firmly resists adopting politically oriented positions during these times of transition. But we should actively encourage open and free discussion of issues in our publications and to facilitate understanding of the issues and to aid in the decision making

process, allowing all points of view to be expressed.

It appears to me that our main concern in the next few years should be to strengthen our image and position as a scientifically oriented body, and we should strive to promote and emphasize any programs or processes which specifically enhance this aspect of the Society.

—James R. Curran

William G. Ely, Bachelor of Science, 1963, Purdue University; Vice President, Research and Development for Maico Hearing Instruments, Inc.; Maico Hearing Instruments, Incorporated, 7375 Bush Lake Road, Minneapolis, Minnesota 55435

I see the American Audiology Society as an extremely important multidisciplinary organization where people with a common interest in the human hearing process can interact to increase their knowledge of hearing, hearing loss, hearing habilitation and rehabilitation. As a society made up of degreed persons with professional interest in human hearing, it should not attempt to represent the professional interests of any one group or academic discipline. I believe that the Society must foster not only written technical information exchange but also provide a forum where members can meet to learn from each other. It is important now and in the foreseeable future for the American Audiology Society, or whatever the membership decides to call the organization, to bring together audiologists, medical doctors, acousticians, engineers, and the many other disciplines who share an interest in human hearing.

[No Picture]

Alan J. Gill, M.D., 1962, State University of New York; Private practice, Otolaryngology. 1305 Post Road, Fairfield, Connecticut 06430.

No scientific society, regardless of its size or purported purposes, can hope to achieve significant progress without the eventual application of its studies being interpreted into practical, day to day applications.

As a privately practicing otolaryngologist, particularly interested in audiology, it would be my hope and aim as an Executive Committee member of this Society to help guide our work into such avenues, in order to provide the best, the most up to date, and the most reliable information in the diagnosis, care and treatment of our patients.

A. Bruce Graham, Ph.D., 1953, Northwestern University. Chief, Division of Audiology, Speech and Language Pathology at Henry Ford Hospital. Henry Ford Hospital, 2799 West Grand Boulevard, Detroit, Michigan 48202.

At the first organizational meeting in which any number of people were present in Dallas, I became fascinated by the opportunity to have an organization which could really sit down and share ideas from all of those involved with hearing problems. We have so many organizations primarily concerned with basic research testing procedures but very little seems to be done about the very real problem of the hard of hearing individual himself. It struck me then as it still does that it would be most worthwhile to have a team of individuals who are concerned with the best possible diagnostic procedures to plan for medical, surgical and educational rehabilitation of the patients to discuss those problems of adjusting to the world of deaf and hard of hearing, to assist in counselling the hearing impaired so they can make the most of whatever their limitation might be. This may involve amplification, it may involve special auditory training, lipreading, but it is truly involved around those with hearing problems.

Earl Harford, Ph.D., 1958, Northwestern University; Professor of Audiology and Director of the Division of Hearing and Speech Sciences, School of Medicine, Vanderbilt University; Director, Bill Wilkerson Hearing and Speech Center, 1114 19th Avenue, South, Nashville, Tennessee 37212

The American Audiology Society was established for the purpose of increasing the knowledge of human hearing, promoting conservation of hearing and fostering habilitation and rehabilitation of persons with hearing impairment. This is the only organization of its size in the U.S. with these objectives as its foundation. This Society offers a

forum for those who identify with these objectives, regardless of country of residence and specific area of professional or scientific discipline. The Society is unique in the sense that its focus is limited to human hearing and yet is unlimited in its composition of members. It consists of persons with different credentials, roles and expertise. The Society serves as a vehicle for these persons to merge in a common cause for the good of the hearing impaired. Anyone with a degree from a recognized institution and a professional interest in human hearing is eligible for membership. This open door policy fosters healthy interdisciplinary interaction which must be considered an ideal requisite to the advancement of knowledge in hearing science and rehabilitation. A single profession cannot effectively deal with the enormous complexities of human hearing and its disorders. The American Audiology Society has a bright future. To realize the potential of the American Audiology Society, each member must assume responsibility to contribute in some manner. These contributions can take many shapes, e.g., research in any of its forms, questions, application of shared and learned ideas, teaching, challenges to others, but most important a constructive involvement in the goals of the Society.

Chauncey Hewitt, BBA, 1956, Hofstra University. President, The Vicon Instrument Company, 828 Wooten Road, Colorado Springs, Co. 80901.

When I first considered membership in the AAS, I was primarily motivated by a desire to see progressive and contemporary thinking individuals break with the polarizing effects of the various disciplines to promote the necessary investigations to increase our knowledge of human hearing. I felt then, and feel even more strongly now, that a close inter-disciplinary exchange is essential if we... anyone concerned with the future of persons with hearing impairments... are to produce a cross fertilization of thought and activity to solve a common problem.

We are approaching an era where multi-disciplinary activities must be provided because the hearing impaired community is crying for them and the various governments are sensitive to those cries. If we, as an organization, do not break down the interdisciplinary barriers, the necessary services will reach the hearing impaired in a less ef-

fective and uncoordinated manner.

Susanne Kos, M.S., 1975, North Texas State University. Clinical Audiologist, University of Texas at Dallas Callier Center for Communication Disorders, 1966 Inwood Road, Dallas, Texas 75235.

As one of the original members of the American Audiology Society, I am proud to be part of an emerging organization whose aim has been to promote a perception of unity among the varied facets represented by our membership. The conception of a multidisciplinary society has afforded us a unique opportunity to share, and through the journal series as a forum for continuing education, to disseminate current philosophies and developments in our related fields of endeavor. Hopefully, this organization will continue to prosper with our expertise and ideas forged into a single effort to better serve the hearing impaired populations in all aspects of diagnosis and rehabilitation.

Mark Lawrence, Ph.D., 1944, Princeton University. Professor of Otolaryngology and Director of the Kresge Hearing Research Institute, Department of Otorhinolaryngology, University of Michigan Medical School, University of Michigan Medical School, Ann Arbor, Michigan 48109.

In the late 1940s, when the word "Audiology" was being widely promoted it was being widely included everyone whose activities involved the ear and hearing: otologists, audiometric technicians, biologists, physicists, etc. This was all spelled out in a little book titled *Audiology* published in 1949 by Norton Canfield, M.D. In his forward he said: "Although the science of hearing is not new, the term 'Audiology' expresses a new concept. It includes all of the separate professional abilities which contribute to this rapidly progressing specialty."

But since that time, paralleling, and as a consequence of, the growth of ASHA the term 'Audio-

THE INTERROGATORY

(Cont. From Page 3)

logy" has come to designate a profession, much respected and requiring certain prescribed qualifications. So now the study of hearing involves the audiologist and other specialties as well. That is why I would like to see a name change for this organization.

In the future development of this society there should be no suggestion that one's educational background governs the group's interest. Rather, I would hope, it is the common interest, hearing, that governs the membership and activities. Thus, an audiologist is only one strong part of the organization, and there are others consisting of bioengineers, neurophysiologists, biophysicists, otologists, etc., all with the common goal of understanding hearing, deafness, and we should add the balance system.

We cannot all be expert in all fields so this organization should provide the forum where different specialty backgrounds can focus on a common area to provide a cross-fertilized understanding of the mutual interest with which all are concerned.

Fred Linthicum, M.D., 1946, University of Southern California School of Medicine. Member of Otologic Medical Group, Inc.; Director of Education and Temporal Bone Laboratories, Ear Research Institute; Clinical Professor of Otolaryngology, University of Southern California School of Medicine. 2122 West Third Street, Los Angeles, CA 90057.

The American Audiology Society performs a very important function in producing a closer liaison among the audiologists, otolaryngologists, and others interested in the preservation and improvement of communication problems. The journal, *Corti's Organ*, and the meetings bring together people with various backgrounds so they can discuss mutual problems. It is not rare these days that one discipline concerned with hearing is unaware of what is going on in the other. These publications and the meetings serve to distribute this information.

Samuel F. Lybarger, B.S., 1930, Carnegie-Mellon University. Self-employed as acoustical consultant. 101 Oakwood Rd., McMurray, Pa. 15317.

The American Audiology Society fills a very important need in bringing together the various disciplines involved in assisting those with hearing impairment. It can bring together the medical, audiological, acoustical, electronics, dispensing and other fields in a way that each can respect the other and can benefit from the experience of others. This should be the primary objective of the society.

The Society has made an excellent start in the quality and scope of its two publications and they should be supported to the fullest extent.

With respect to meetings, I feel that a problem exists. We need to study ways in which greater attendance can be achieved. Perhaps the idea of regional meetings should be explored.

We are fortunate in having an excellent management at our headquarter's office.

With the real need for the existence of a society with the objectives of AAS and the good start the society has made, I foresee for it a successful and meaningful future.

Harris Pomerantz, M.Sc., 1954, Syracuse University. Private practice in Audiology, Tampa, Florida, and Lakeland, Florida. Also clinical instructor in surgery, University of South Florida, Tampa, Florida. 515 Bay Street, Tampa, Fla. 33606.

The aims of the American Audiology Society relating to increasing knowledge of human hearing, promoting conservation of hearing and fostering habilitation and rehabilitation of persons with hearing impairments by coordinating and disseminating information, are most worthy and many groups subscribe to them. Nowhere else however, are these aims the primary concerns of any group whose membership runs the gamut of concerned professionals from all groups focusing hearing and from all levels of interest from basic sciences through diagnosis and treatments to prosthesis and governmental regulation.

Of particular concern to me is the fractionalization and polarization of efforts and thinking brought on by our faulty perceptions and confused imagery of roles and economic impact on each other. I perceive the AAS as a forum to enhance cooperation and dispel myths in the arena of hearing services.

It is to help in continuing the effectiveness of the American Audiology Society, by such writing and representation as I may contribute, that I stand for election to the Executive Committee.

Loring W. Pratt, M.D., 1943, Johns Hopkins University School of Medicine, Chief, Department of Otolaryngology, Mid-Maine Medical Center, Waterville, Maine. 325B. Kennedy Memorial Drive, Waterville, Maine 04901 [office]

The American Audiology Society, by virtue of the diverse composition of its membership who possess a common interest in Audiology, is in a unique position to foster cooperation and develop both understanding and harmony among various disciplines. The development of programs designed to increase our knowledge of hearing, its problems, and methods of conservation and rehabilitation by utilizing input from this diverse group should result in more effective utilization of our talents, for the ultimate benefit of the patient.

The American Audiology Society should keep these as their goals and endeavor to spread this message among Otolaryngologists and Audiologists with the aim of encouraging all with a common interest in problems associated with hearing and its deficits to work in harmony for a common purpose.

J. Buckminster Ranney, Ph.D., 1957, Ohio State University. Chief, Scientific Evaluation Branch, National Institute of Neurological and Communicative Disorders and Stroke, National Institutes of Health. NIH NINCDS SEB, Federal Building, Room 9C-10, 7550 Wisconsin Avenue, Bethesda, Maryland, 20014.

The American Audiology Society has established itself as a forum for the exchange of ideas, viewpoints, and concerns in a spirit which is not constrained by the artificial barriers of discipline. The continuing purpose of the Society is to foster the personal and intellectual exchange and interchange among those persons concerned with hearing impairments. A viable future for the Society demands that energies not be dissipated with petty concerns, e.g., name changes; rather the effort of the member-

ship and the officers should be directed to furthering dialogues which encourage an increasing number of persons to put aside insularity for a common good.

Michael F. Siedemann, Ph.D., 1973, Florida State University, Coordinator of Audiology, Associate Professor of Audiology and Speech Pathology, Louisiana State University Medical Center, 1100 Florida Avenue, Building 163, New Orleans, Louisiana 70119

It appears to me that the American Audiology Society has thus far performed an excellent job in achieving most of the aims of the Society designated in the Statutes. The exchange of information at the meetings and in publications has been commendable for a society in its youth.

There is one area addressed in Article 2 of the Statutes that I feel warrants an increased concentration of effort by the Society. The area to which I refer is promotion of the conservation of hearing. In the near future, each of the disciplines represented within our society must come forward to a place of leadership in the promotion of hearing conservation. At the time of this writing (prior to the promulgation of new OSHA regulations), it seems that the likelihood of requiring audiological involvement in industrial hearing conservation programs is poor. While the vast majority of industrial hearing conservation will be undertaken by technicians and industrial physicians, audiologists, and otolaryngologists must serve as consultants to such programs. The application of our knowledge and skills in the realm of hearing is a necessary component in any successful hearing conservation program.

In the future, therefore, I would like to see increased involvement in this area by our society.

John C. Sinclair, Ph.D., 1962, Illinois Institute of Technology. Director of Engineering Research & Development, HC Electronics, Inc. 250 Camino Alto, Mill Valley, California 94941

As an Engineer in a company whose products are solely related to the Hearing Health Care field, I am particularly desirous of affiliating with related professional societies.

I especially endorse the aims of

the American Audiology Society with respect to increasing knowledge of human hearing and the promotion of hearing conservation, habilitation and rehabilitation.

Wayne J. Stabb, Ph.D., 1971, Michigan State University. Director of Education, Telex Communications, Inc., 9600 Aldrich Avenue South, Minneapolis, Minnesota, 55420.

The American Audiology Society should continue the aims as expressed in Article 2 of the AAS Statutes. It should provide a non-political independent medium for interaction by its multi-disciplinary membership and continue to pursue the variety of membership consistent with the goals of AAS.

AAS should actively continue to pursue recognition as the official representative to the International Audiology Society. The United States should be represented by an organization where the entire membership has a legitimate interest in audiological pursuits. AAS is the only United State organization which has a membership and goals consistent with other international audiology society members.

AAS should investigate establishing official liaison with membership background areas represented whenever feasible. This would be in addition to the Executive Committee representation in dealings with third parties which already exists.

W. Dixon Ward, Ph.D., 1953, Harvard. Professor, University of Minnesota. Depts of Communication Disorders, Otolaryngology, Environmental Health, and Psychology. 2630 University One S.E., Minneapolis, Minnesota 55414.

The Society should seek to advance knowledge of the audiology process on the part of its members, those who need assistance in problems of hearing, and the general public. It should have nothing whatsoever to do with questions of monopolies of service, distribution of fees, public aggrandizement.

American Audiology Society

Directory

The following persons were listed as current members of AAS as of March 1, 1977.

Alphabetical Listing

ABER, WILLIAM

Audiology Dept.
Mountainside Hospital
Montclair, N.J. 07042
ADELMAN, SHARON
Vancouver General Hosp.
Vancouver, B.C.
Canada

AHAUS, WILLIAM H.

VA Hospital
921 Northeast 13th St.
Oklahoma City, Ok. 73014
AHRENS, ROBERT P.
23-15 Broadway
Fair Lawn, N.J. 07410

ALBERTI, P.W.

Mt. Sinai Hospital, Rm. 405
600 University Ave.
Toronto, Ontario
Canada M5G 1x5
ALBRIGHT, PAULETTE
4617 Stuart Av.
Richmond, Va. 23226

ALLARD, J. BRAD

P.O. Box 484
1 B Spruce St.
Fulton, Ma. 65251
ALLEN, SYLVIA K.
Army Audiology & Speech Ctr.
Forest Glen Section, Bldg. 156
Walter Reed Army Med. Ctr.
Washington, DC 20012

ALLEN, DORIS V.

Wayne State University
Department of Audiology
261 Mack Blvd.
Detroit, Mi. 48201
ALLISON, RICHARD E.
2215 Pleasant Av.
Lakeview, NY 14085

ALLUISE, MARY JANE

1421 Rylands Rd.
Virginia Beach, VA 23455
ANDERSON, LLOYD C.
825 Murchison Dr.
Millbrae, CA 94030
ANDERSON, MARCIA LEE
275 Middleneck Rd.
Gredt Neck, NY 11023

ANDERSON, ANNE MARY

32 Village Ct.
Midland, TX 79701
ANDERSON, VIRGINIA S.
St. Vincent's Infirmary
Markham & University
Little Rock, AR 72201

ANDERSON, CHARLIE D.

Tracoustics, Inc.
P.O. Box 3610
Austin, TX 78764
ANGELLI, ROGER M.
Chairman, Dir. of Audiology
Mercy Hosp.
Pittsburgh, PA 15219

ANTHONY, W. P.

662 S. Henderson
Ft. Worth, TX 76104
ARMSTRONG, JOHN W.
406 N. Saginaw St.
Flint, MI 48502

Science Abroad

Editor: W. Dixon Ward

(With this issue we begin a new section featuring reviews of outstanding articles from foreign journals. Our accomplished linguist and ex-president, Dix Ward, has graciously agreed to supply the reviews.)

Dieroff, H.G.: "Larmschwerhörigkeit" Leitfaden der Larmhorschadenverhütung in der Industrie. Johann Ambrosius Barth, Leipzig, 1975. 312 pp., 254 fig., 17 tab.

Ever since the appearance in 1963 of Professor Dieroff's learned Habilitationsschrift, Die Larmschwerhörigkeit in der Industrie, many of us have urged him to expand it to a full-length book suitable for a classroom text on this timely and important subject. He has now done so, and the result can only be described as a classic in the best sense of the word.

After a short introduction, the presentation begins with an excellent 20-page section on the physical measurement of sound contributed by Professor W. Reichardt of Dresden. Though highly concentrated, the important facts relating to the measurement and specification of steady and impulsive noises are clearly expressed, and although the chapter goes a bit beyond pure physical acoustics (e.g., presenting risk criteria and age corrections for audiometric data), it serves as a most adequate basis for the rest of the volume.

Next Dieroff, in just 55 pages,

presents a masterful account of audiometric theory and practice as they bear on the problem of the differential diagnosis of noise-induced hearing loss, beginning with audiometric zero and artificial ears, and ending with the detection of malingering. Standardized tests for sensory losses are catalogued and described with impeccable thoroughness, including many that are relatively unfamiliar to English-speaking audiologists, such as noise audiometry and the tests of Keitz, of Langenbeck, and of Feldmann. The analysis is as up-to-date as one can reasonably expect in this age of burgeoning experimentation, although I must confess that I winced to see an old graph of mine on contralateral remote masking (CRM) that illustrated—or so I thought at the time—the action of the middle-ear muscles, an opinion that had to be abandoned when it became clear that CRM is little affected by conditions that are known to render the muscles inoperative.

The major portion of the text, the next 150 pages, covers succinctly but clearly the literature on temporary and permanent effects of noise, physiological and psychophysical, as determined both in the laboratory and in the field. Although special emphasis is given to tying together the dozens of studies done by Dieroff and his colleagues and students in Jena, the entire world literature is meticulously integrated.

Their own studies include noise and hearing-loss measurements in a large range of steady and impact-noise environments; 70 spectra comprise an Appendix, and details of audiometric surveys are also included. My only major criticism here is that in my opinion, an undeserved degree of credence is given to the hoary concept of the "critical intensity" of a sound for producing damage, as contrasted to some kind of "critical exposure" that takes into account both intensity and duration; on the other hand, one must admit that it is a notion that is still firmly entrenched in the thinking of many persons (including, but not restricted to, laymen).

The text concludes with a short section of the problem of assessment of handicap associated with hearing loss, followed by the Appendix mentioned earlier and by 18 pages of references (ca. 500) that comprise the literature synthesized.

Physically as well as technically, the book is of top quality, with only a few minor typographical errors such as a reversal of male and female presbycusis curves on p. 23.

In summary, we are fortunate that a scholar of Professor Dieroff's competence has taken the time to produce this excellent book on noise-induced hearing loss. It is to be hoped that it will soon be translated into English.

Meeting

Announcement —Call for Papers

SENTAC (The Society for Ear, Nose and Throat Advances in Children) will meet in Chicago, Illinois at the Children's Memorial Hospital and the Continental Plaza Hotel October 29-30-31, 1977 (Sat.-Sun.-Mon).

The participation of those interested in pediatrics, audiology, speech pathology and otolaryngology is solicited. Please submit abstracts (in quintuplicate) to: Gabriel F. Tucker, Jr., M.D., Program Chairman, The Children's Memorial Hospital, 2300 Children's Plaza, Chicago, Illinois 60614.

Deadline for receipt of abstracts is June 15, 1977.

Fellowship Awards NINCDS Announces

The Communicative Disorders Program of the National Institute of Neurological and Communicative Disorders and Stroke will make National Research Service Individual Fellowship Awards in the area of Audiology to:

Derek E. Dunn
Dewey W. Grantham
Nancy K. Squires

National Research Service Institutional Fellowship Awards in the NINCDS Communicative Disorders Program will be made to: Louis Braidia
Massachusetts Institute of Technology
Gerald Canter
Northwestern University
Lois Elliott
Northwestern University
Joseph Hawkins
University of Michigan

Michael Paparella
University of Minnesota
William Peake
Massachusetts Institute of Technology

A CLASSIC OF TEMPORAL BONE PATHOLOGY

A meeting featuring
Dr. John Lindsay
and
Dr. Imre Friedmann

Will be held May 21st at the University of Colorado Medical Center. These world-famed experts of temporal bone pathology will talk on interesting cases from their files.

If interested write:
Dr. Bruce Jafek
University of Colorado Medical Center
Denver, Colorado 80220

SPECIAL REPORT

Report on Evaluation of Subjects Presently Fitted With Implanted Auditory Prosthesis

The, "Do they work or don't they work" controversy over electrical auditory implants finally made it through to the, "let's find out" stage. In July, 1975, a competent group of investigators at the Pittsburgh Eye and Ear Hospital began an in-depth evaluation of 13 persons wearing single-channel electrical auditory prostheses. That investigation was completed in January 1976, and the summarized results were reported in October, during the AAOO meetings. The written report for this NIH Contract No1-Ns-5-2331 consists of a 256 page volume and a 198 page appendix. Inside these pages is enough solid data on what these persons hear (with or without the devices) to keep anyone busy for the better part of a week. In fact, the most impressive feature of this study is the amount of work both the experimenters and the subjects devoted to the task. Each patient spent 5 full days in evaluation.

Their report is basically favorable toward the usefulness of the prosthesis for some but not all of the subjects. The data with which to make your own judgment is there in abundance. Unfortunately, the text is about as neutral as it is possible to construct, using English. I would have enjoyed a few opinions scattered around. When the word, significant, is used, they mean exactly that, and usually with the probability ratio close by. It was also clear in these numbers on a few occasions that their subjects were guilty of loading their test responses in favor of the "prosthesis on" condition. Most of us would call that, cheating. They called it a "statistically negative correlation."

The subjects: The deafness of 3 was associated with otosclerosis; 2 were drug-induced; one was leuetic. Seven had no clearly established cause for their deafness. Two were prelingually deaf. Eight had vestibular symptoms beforehand, and of the 10 tested before their implants, all had ENG abnormalities. Because most of the subjects had diminished or absent caloric responses prior to their implant procedures, the effects of the implant surgery itself were impossible to determine. Conventional audiometry showed all but one patient to have profound bilateral hearing losses, without any ability to perceive monosyllabic words. One subject had a 3-frequency average of 78 dB in his unimplanted ear and scored 68% on PBK words. Most

of the subjects either lived or attempted to live in the hearing community and none of them have attempted to integrate with the deaf population.

An impressive battery of neuropsychological tests were administered. Eleven subjects were "roughly within the limits of normal." Two showed definite signs of "organic brain syndrome" and results suggested that these two individuals were likely to have difficulty with classifying stimuli as "same" or "different," etc.

The prostheses: There were two types of stimulators. The 11 subjects implanted by William House had stimulators which produced two electrical waveforms in the cochlea—a steady 16-18 kHz background "carrier" whenever the device was "on", and a superimposed analog "acoustic" waveform which corresponded to whatever the microphone "picked up" from the environment. This environmental signal amplitude-modulated the 16-18 kHz carrier. The variability amongst individual prostheses caused interpretive problems which only really stand out as problems after several re-readings of the full report. Part of the difficulty, for both subjects and experimenters, were the six stimulus adjustments the subjects occasionally decided to modify in the electronics package. These controls were labeled, "sensitivity, carrier frequency, carrier level, modulation limit, symmetry, and percent modulation." Changing these adjustments had a significant effect on subject performance. (I can sympathize with the subjects' problem of trying for a clearer signal. I had my own frustrations and successes in tuning the "cat's whisker on my crystal-set radio when I was eleven.)

The fact that these subjects did adjust their devices *ad libitum* made it impossible to know the characteristics of the electrical stimulus in the cochlea. Furthermore, all the devices themselves differed, some in important ways. Probably the most important of these was the sound input level at which non-linearity became extreme or overmodulation began. Six devices were measured at subject-set gains. Overmodulation began at 50 dB at the lower extreme and at about 75 dB SPL at the upper extreme. It also varied with frequency. Thus, an acoustic signal exceeding these levels, and depending on its frequency, would not necessarily be preserved at the elec-

trode tip in a consistent manner. For example, it is possible that some loud sounds seemed weaker than soft sounds. (These non-linearities also could have caused some confusion about which frequencies/pitches the subjects actually heard and which—usually higher frequencies—were actually the distortion products of the electronics.) In my opinion, the variable performance of these devices (and their distortion products) made it almost impossible for me to know what the real stimulus was in some of the psychophysical experiments.

The stimulating devices used by the 2 Robin Michelson-implanted subjects were not described in this publication. He (Michelson) tells me that one subject's device was coupled to the implanted coil by the audio stimulus itself. The gain across frequencies was adjusted for a more-or-less flat perceptual threshold and included an AGC circuit. The other device was radiofrequency coupled to the implanted coil. The audio signal amplitude modulated this carrier. An internal diode circuit removed the r.f. carrier from the electrode stimulus.

Hearing with the prosthesis: Most subjects adjusted the gain of their devices to thresholds around 50-60 dB SPL. The range was 30 to 90 dB across the 125 to 8000 Hz range in some few instances. (Keep in mind that no pitch discrimination is required to do this, just the awareness of the test sound.) Their Speech Awareness Thresholds were in this same range, and these were 30-40 dB more sensitive than with the prosthesis off. As expected, none were able to score beyond chance during classical Speech Detection Threshold tests or discrimination tests using PBK words.

Studies of the range between threshold, "comfortable" and "uncomfortable loudness" did produce some surprises. The average range from comfortable to uncomfortable in the "prosthesis off" condition was 6.5 dB. With the prosthesis "on" it was 11 dB. The data with the prosthesis off was skewed a little by 2 subjects whose "uncomfortable level" was a few dB less intense than their "comfortable" sound level, and by 2 whose ranges (in the correct direction) were 1 and 2 dB. With the device "on", the subject with a 1 dB tolerance range gave a 20 dB range. Remarkable. Even more remarkable was the subjects' remarkable range, from a minimum of 10 to a maximum of 54 dB. The median was 39 dB. Recall that the maximum dynamic range for an electrical stimulus is in the vicinity of 15 dB. In trying to make sense from this data the authors stress (I think correctly) that it is an error to assume the stimulators vary in direct proportion to the intensity of the sound field. In fact, the stimulators (especially the carrier modulated type) compress acoustic inputs into a very narrow range of electrical outputs. "...the designers of these units have encoded changes in intensity [loudness] in such a

way that the subject is very confused about both loudness and pitch." (p. 106).

Once out from under the constraints of these conventional audiometric tests, things become a little more exciting. Here, I will describe only three tests in enough detail to make the results meaningful.

Recognition of environmental sounds: Twenty-seven (of 50) prerecorded environmental sounds were used because these 27 sounds were all recognized by a panel of 10 normal hearing adults. The subjects were given sets of 4 pictures from the initial set of 50 sounds. One of these 4 was the to-be-identified test sound. "...as a group, the subjects obtained significantly higher scores in the test for ability to identify common environmental sounds when their prostheses were activated than they did when they were off." (56.9% on, 36.1% off). Two subjects scored a highly significant 0% correct with the prosthesis off whereas random chance predicted 25% correct. Of the 11 subjects, 5 performed significantly above chance levels with their prostheses activated and only at chance levels when it was off. (One of my between-the-lines readings of this report seems verified here. Some subjects seemed prejudiced in favor of yielding "good" scores with their device and "poor" scores without them. Fortunately this kind of enthusiasm did not prevail among most subjects.)

Lipreading skills: The Craig Lipreading Inventory was the test instrument used—33 words and 24 sentences—in both live voice and TV tape modes. A total of 10 tests were used—no sound, sound with prosthesis off, on, etc. When averaged across all tests, the mean score with the prosthesis was 87% and without it, 79%. I am not familiar with the Craig Test, but it seems clear, especially in the live voice mode, that it was too easy for most subjects. After some discussion and statistics, the authors conclude that for 8 subjects the prosthesis did not affect lip reading scores. Three showed better scores with the prosthesis, but not at statistically significant levels. Two subjects' results were the subject of some discussion, without clear conclusions. Thus, I am left with the impression that the prosthesis might have helped a bit but was not impressive, and that the investigators wished in retrospect they had used a more difficult instrument to measure lip-reading ability in these obviously talented subjects.

Subjects' speech intelligibility: Two speech samples each for the prosthesis "on" and "off" conditions were recorded during their week-long evaluation. The material for these monologues differed from subject to subject, according to their interests and abilities. These tapes were randomized and audited afterwards by 10 normal-hearing adults who had not been involved with other subject evaluations. The listeners were asked to rate intelligibility of a 0 to 100% scale. "...the mean

intelligibility ratings for speech samples obtained with the prosthesis was activated were significantly higher than those obtained when the prosthesis was off ($F=26.12$; $df=1.9$; $p=0.0$). The mean intelligibility rating for the prosthesis-activated condition was 67.0% and that for the prosthesis-off condition was 60.0%. The reliability of the judgments was 0.98." (p. 202) Improvement-with-prosthesis came from 4 subjects. Those very good scores without prosthesis had little room to prove with it on, and those had "extremely poor" speech not improve with the aid of a stimulator.

Psychoacoustics: The results of the foregoing three studies are clear. The results of the psychophysical measurements are not as easily interpreted as was not comfortably assured by many of the graphs and figures really displayed what their figures advertised. The investigators had similar anxieties. The problem seems to have been of two possibilities: 13 different types of implanted ears or 13 different stimulators with minor and minor differences between them. Picture, for example, trying to design a two-day experiment on pure audition in which each "middle ear" and "cochlea" responds differently, even sometimes backwards to what might expect. Having reached a SPL of, say 65 dB, for example, additional increments of intensity have a 50/50 chance of causing a decrease in loudness. Changes might truly be pitch changes, or a loudness confusion, or a non-linearity in the electronics. Also keep in mind this type of "hearing testing" is innately boring.

The basic design of all experiments on abstract sound quality such as pitch and loudness "detect the one stimulus (or that is different)." While this is a good approach in normal (linear) sensory systems, it leaves a hole in the evaluation of a linear system. This design cannot identify the nature of the quality judged different from the other three. If, for example, an experimenter varies the frequency of the test sound, the subject cannot be assured that the subject made his same-different judgment by a pitch change instead of a loudness or envelope cue. Still, I doubt if the session could have been constructed much differently within the constraints and the subjects' vetoes. The one-choice-in-four design got results.

The subjects did surprisingly well in both pitch and loudness discriminations at low frequencies, 125 and 250 Hz, and deteriorated (at differing rates) at these frequencies. Occasionally some discriminations were possible at 2,000 but these were unusual. I found it difficult to believe that the 125 Hz discriminations were normal for 8 (of 13) subjects, and were within or normal for 6 subjects at 250 Hz. The fact that 3 subjects still

FDA Rule Encourages Hearing Aid Use

New Food and Drug Administration regulations for labeling of hearing aids and conditions for their sale will increase consumer confidence and encourage more people to get hearing aids, according to John Blake, Executive Director of the Hearing Aid Industry Conference, a Washington, D.C.-based trade association which represents hearing aid manufacturers. The rule, effective August 15, 1977, will provide for a medical evaluation prior to the purchase of a hearing aid, with a right of waiver for fully informed adults over 18. The rule requires a brochure to accompany each hearing aid, which will explain the health-related aspects of obtaining a hearing aid, the care and use of the aid, and where to get it serviced.

Blake stated that the rule will not be easy for all manufacturers to implement, but "we are confident that industry members will make every effort to quickly adhere to the new requirements."

"While we are not convinced

that all the requirements are necessary," says Blake, "we do think that FDA, has been fair and realistic about the vast need for more attention to the problems of the hearing impaired. There are a lot of people who could hear better with a hearing aid, and we feel that this regulation will encourage them to get hearing help."

The Commissioner of FDA has recognized the major role that personal motivation plays in getting assistance for hearing problems and has also indicated that some selling practices and techniques used by the industry have helped to strengthen motivation to buy a hearing aid. The medical evaluation is simply to assure that medically treatable conditions that may affect hearing are identified and treated before a hearing aid is purchased.

In commenting on industry's reaction to the rule, Blake stated "This rule is the result of a long and complex dialog between industry, professional and consum-

er groups and the government on medical care for hearing problems and the purchase of hearing aids. The rule establishes, for the first time, a definitive role for the doctors, the audiologist, and the hearing aid dispenser in providing hearing health care and sets forth industry requirements for dissemination of uniform consumer information on hearing aids. FDA has acknowledged that hearing aids are not dangerous devices and that the number of people who will in fact require medical or surgical treatment is relatively small in comparison to the number of individuals who may benefit from amplification."

Blake continued, "There are millions of people who have never done anything about their hearing impairment. It is the industry's belief that in working with government through this comprehensive consumer regulation, we will be able to encourage those people to enrich their lives through the use of a hearing aid."

Article and Book Reviews

NORTHERN, JERRY L. [Ed.]
"Selected Readings in Impedance Audiometry." Dobbs Ferry, New York: American Electromedics Corporation [1976]. 389 pp.

Reviewed by **Thomas P. White**, Assistant Professor, Div. of Communicative Disorders and Sciences, State Univ. of NY at Buffalo.

Selected Readings in Impedance Audiometry is an important contribution to the study of the development and application of electro-acoustic impedance technique. Dr. Jerry Northern has selected and edited forty-six journal publications, by both researchers and clinicians, which have been instrumental in the ex-

traordinarily rapid acceptance of this clinical procedure. Such a compilation can be difficult because controversy will arise as to the significance of any particular work. However, in this volume, there is little room for criticism in that most are widely accepted as landmark papers in impedance development. The papers are divided into seven sections with each devoted to a different aspect of electro-acoustic impedance.

Section I, "Introduction to Impedance Audiometry," contains ten articles concerned with the bases of impedance measurements and its applications. Section II, "Tympanometry," consists of seven papers dealing with tympanometric measures and inherent variables such as the effect of probe tone frequency. Sections III (six papers) and IV (eight papers) cover "The Nature of the Acoustic Reflex" and "Clinical Applications" respectively. Information is presented on the anatomy of the stapedial reflex arc and applications of reflex testing in assessing central disorders and the prediction of sensori-neural hearing loss.

These two sections are supplemented by Section VI, "Non-acoustic Stimulation of Middle Ear Muscles." The four articles in this section complete the topic of the use of the middle ear muscle reflex measurement in assessing middle ear and inner ear integrity. In Section V, four publications are presented which discuss the importance of impedance measurement in "Eustachian Tube Evaluation." Finally, the four articles in section VII, deal with the role of "Impedance as a Screening Technique."

This book certainly is important to the academician. An individual teaching a graduate course in audiology which covers the topic of impedance will find this volume indispensable. Since most graduate work is to some extent research oriented, "Selected Readings..." will enable efficient use of student time and provide a useful supplement to the teaching of impedance audiometry. Dr. Northern's book is also extremely valuable to the clinician. Many of the papers are clinical in nature and consequently present much normative data that can be used as a reference for clinical work. With the remarkably rapid development of impedance audiometry, the value of this book cannot be overemphasized.

PROGRAM:

Central Auditory Dysfunction May 19-20

GUEST FACULTY

Daniel S. Beasley, Ph.D.
Memphis State University

Mary Rose Costello, Ph.D.
Henry Ford Hospital, Detroit

Charlotte Dempsey, M.A.
West Chester State College
West Chester, Pennsylvania

Drake D. Duane, M.D.
Mayo Clinic

Jack Katz, Ph.D.
State University of New York at Buffalo

Robert W. Keith, Ph.D.
University of Cincinnati Medical Center

George E. Lynn, Ph.D.
Wayne State University, Detroit

Marilyn L. Pinheiro, Ph.D.
Medical College of Ohio at Toledo

Sylvia O. Richardson, M.D.
Cincinnati Center for Developmental Disorders, Children's Hospital Medical Center

Jack Willeford, Ph.D.
Colorado State University

FEE

\$80.00 (includes lunch on Thursday and Friday)

\$20.00—The first 100 students will be enrolled for \$20.00 but registration form and check MUST be accompanied by a letter from faculty advisor stating that the student is a registered, full-time student during Spring Qtr., 1977. Fee includes lunch on Thursday and Friday.

PROGRAM

May 19

8:15 REGISTRATION
8:45 Welcome/Introduction: KEITH
9:00 DUANE: Central Auditory Dysfunction: A Neurologist's Point of view.
10:30 INTERMISSION
10:45 WILLEFORD: Test Battery Approach; Binaural Fusion; Binaural Separation; Filtered Speech; Alternate Speech Perception Tests
11:45 LUNCH
1:00 KEITH: Synthetic Sentence Identification Test
2:00 KATZ: Staggered Spondaic Word Test
3:00 INTERMISSION
3:15 BEASLEY: Compressed Speech
4:15 QUESTIONS/ ANSWERS

MAY 20

9:00 LYNN: Evaluation of Central Auditory Dysfunction in Adults with Neurological Disorders
10:00 PINHEIRO: Tests of Central Auditory Function in Children with Learning Disabilities
11:00 INTERMISSION
11:15 COSTELLO: Evaluation of Central Auditory Function with Children Using the Flower-Costello Test
12:00 LUNCH
1:00 RICHARDSON: Communicating Results of Central Auditory Test with Other Professionals
1:40 GUEST PANEL: Practical Considerations of Central Auditory Tests
3:00 INTERMISSION
3:15 PANEL: Opportunity for Comments from Guest Faculty Q/A from Audience.

For further details and registration information contact:

Robert W. Keith, Ph.D.
Division of Audiology and Speech Pathology
University of Cincinnati College of Medicine
231 Bethesda Avenue
Cincinnati, Ohio 45267
Telephone: (513) 872-4241

PURPOSE

To provide a forum for a meaningful exchange of information and ideas on the current diagnostic approach to problems of central auditory dysfunction.

Emphasis will be on behavioral testing with special reference to clinically-useful diagnostic procedures. We want the audience to leave the symposium with a better understanding of the present status of testing for central auditory dysfunction in children with learning disabilities and adults with lesions of the central auditory nervous system. We also hope that the audience will have some insight into the direction and role of central auditory testing in the future.

The Symposium will be held in Kresge Auditorium at the University of Cincinnati College of Medicine.

SYMPOSIUM ON IMPEDANCE SCREENING FOR CHILDREN

Current Status for Detection of Middle Ear Disease

June 20-22, 1977

Division of Hearing and Speech Sciences
Vanderbilt University School of Medicine
Nashville, Tennessee
Monday, June 20

Opening: Earl R. Harford, Ph.D., Vanderbilt University School of Medicine
Don A. Harrington, Ph.D., Bureau of Maternal and Child Health, HEW

PROGRAM

I. MIDDLE EAR DISEASE IN CHILDREN

"Epidemiology and Natural History of Middle Ear Disease"
Jerome O. Klein, M.D., Harvard Medical School

"Morbidity of Middle Ear Disease"
Charles D. Bluestone, M.D., University of Pittsburgh School of Medicine

"Methods of Identification for Middle Ear Disease"
Gunnar Liden, M.D., University of Goteborg, Sweden

Summary and Charge: Fred H. Bess, Ph.D., Vanderbilt University School of Medicine

II. INFANTS

Moderator and Discussion Leader
Jerome O. Klein, M.D., Harvard Medical School

Present State of the Art
Robert Margolis, Ph.D., University of California, Los Angeles

Contributed Papers:

"Impedance Measures in Infants from Birth to Six Months"
Geary A. McCandless, Ph.D., University of Utah School of Medicine

"Tympanometric Screening of Normal and Intensive Care Unit Newborns: Accuracy and Validity"

[Continued on Page 15]

Special Report

[Continued from Page 12]

normal-range pitch discriminations at 500 Hz is consistent with nothing short of miracle status. But then, a near miracle is what we are hoping for anyway with prosthesis research. "...Statistically, the most consistent finding in these frequency discrimination experiments is that subjects tested with auditory prostheses discriminate frequency differences quite well in the vicinity of 125 Hz. When signal frequency is raised to 250 Hz, however, many of the subjects begin to have difficulty with frequency discrimination; and their difficulties increase when frequency is raised further." (p. 159).

Speech-like sounds: One-half octave glissandos with base frequencies of 250, 500, and occasionally 1000 and 2000 Hz were distinguishable at better than chance levels about two-thirds of the time when the glide ended with a tone pulse but only rarely when the stimulus began. On a few occasions an octave glissando could be detected when the half-octave could not. When tested, the implanted ear performed about the same. Computer-generated synthetic speech sounds were tried, one glottal pulse and one-formant vowel-like sound. Three subjects scored better than chance on all comparisons. For others fell below chance on one comparison. The subjects experienced the most difficulty with comparisons between formants with adjacent frequencies. They were, on the whole, able to discriminate 3 sets of vowel pairs about two-thirds of the time given.

The investigators commented further on the perplexing success the subjects demonstrated with speech sound discriminations in a single channel of electrical stimulation. They felt that stimulators themselves produced speech-like signals in such a way that clear temporal, rather than spectral cues, were available. Further, for the vowel-like sounds, there were intensity differences between some of the pairs.

Vestibular effects: A computer-controlled transducer system was used in the evaluation of the subjects postural stability (an elegant extension of the classic Romberg Test). All subjects showed abnormal posture control which increased during visual deprivation. With the prosthesis in quiet, 7 subjects had further increases in postural instability. Four had a further increase in stability when tested in a noisy background, and 3 improved their stability in this background. Electrical stimulation is not limited to the auditory system.

There is much more material in the report than mentioned in this review, including recommendations for future research. This is an excellent job and a good example of how to do research under difficult circumstances in limited time.

"Surgical Anatomy and Techniques of the Temporal Bone" course. Eye and Ear Hospital, Pittsburgh. Write to: Ralph J. Caparlosa, M.D., 3600 Forbes Avenue, Pittsburgh, Pennsylvania 15213.

DECEMBER 12

American Audiology Society, Miami Beach, Florida

DECEMBER 13-16

Acoustical Society of America Meeting, Miami Beach, Florida.

Collette Ramsey, founder of the Deafness Research Foundation at Mid-Vail with immediate past President, Dix Ward.

AAS President Geary McCaudless with three of his five Hot-doggin' sons, Raymond, Phillip and Allan, ready to take off at Vail.

Sandy Gerber and Vern Stroud at the Columbus Public Health conference.

'We Overcame Hearing Loss'

Thirteen prominent Americans from different walks of life tell how they overcame their own hearing problems in Better Hearing Institute's exciting new edition of "We Overcame Hearing Loss."

Included are photos and personally signed success stories of personalities in football, television, boxing, movies, politics, theater, music, business—people like Academy Award-winning Best Actor Art Carney, comedian Norm Crosby, actress Nanette Fabray, Governor George Wallace, singer Johnnie Ray, football star Larry Brown, and more.

Each acknowledges his or her own hearing loss and encourages

others who suspect a problem to seek help.

"We Overcame Hearing Loss" will help to inform and inspire the hearing impaired, their families and friends. Copies can be distributed at Better Hearing and Speech Month events, in waiting rooms, at speaking engagements, or by mail. (1430 K Street N.W., Suite 200, Washington, D.C. 20005).

Better Hearing Institute is a nonprofit educational organization dedicated to informing and educating consumers and the general public about hearing and speech problems and where to go for help.

Noise Report Solves Issues

OSHA need no longer concern itself with problems of noise measurement. The ultimate description of noise sources has been cogently reported by a scientist at the University of Minnesota in Chemistry (Vol. 50,

No. 6).

The researcher has made exhaustive sound spectrographic analyses of various foods, arriving at a cognitive system for classifying the parameters of Crispiness. Devotees of Snap,

Crackle, Pop will rejoice to find the upper spectrum of noisy-crispy / quite-not-crispy specified:

- Wet-crisp is exemplified by the crunch of celery or green peppers, caused by a fluid under pressure called turgor which explodes expansively under the force of the tooth bite. An arithmetic ratio exists between the amount of turgor and the sound pressure of the crunch.

- Dry-crisp is found in crackers, whose brittle air-filled cells bend and break. "The shattered fragments snap back to position, generating vibrations that build up into a sound pressure wave."

- Chip-crisp occurs in the common potato chips, only a few cells thick. The curvature of the chip results in repeated fractures when bitten into, producing a multitude of sound sources. The unexpectedly high intensity of sound thus generated gives a consummate ecstasy to aficionados.

Eat your heart out, OSHA!

Central Auditory Dysfunction

On May 19 and 20, 1977, approximately 250 registrants attended a Symposium on Central Auditory Dysfunction that was hosted by the Division of Audiology and Speech Pathology, University of Cincinnati Medical Center. The symposium was sponsored in part by the National Foundation March of Dimes. A guest faculty of 14 persons shared their knowledge and experiences in central auditory testing during the two-day conference.

The first part of the symposium dealt primarily with discussion of tests and test batteries. The different speakers presented various tests that have been devised and described their implications for use. Jack Willeford presented the Colorado State University Willeford Test Battery, Robert W. Keith shared the Jergers' material on the Synthetic Sentence Identification Test, Jack Katz explained the Staggered Spondaic Word Test, Daniel Beasley discussed time altered speech tests and Mary Tose Costello reviewed the use of the Flowers-Costello test of central auditory abilities.

The application of these and other tests on children and adults was the subject of the next part of the conference. Marilyn Pinheiro spoke on the use of a test battery with learning-disabled children and George Lynn reviewed the evaluation of central auditory dysfunction in adults with neurologic problems.

The next segment of the symposium dealt with the physician's

view of the tests. Dr. Drake Duane talked about a neurologist's point of view of central auditory dysfunction and Dr. Sylvia Richardson spoke on communicating results of central auditory tests with other professionals.

The final segment of the symposium was a panel discussion on practical considerations of central auditory tests. This panel discussion was headed by Charlotte Dempsey. Travis Milliken, Emily White and Richard Sweitzer reported on their experience with central tests in private practice settings and in a multidisciplinary children's hospital. After each day there was time set aside for the guest panel to further discuss issues and to deal with questions from the audience.

The proceedings from the symposium are being published by Grune and Stratton and are expected to be in print by October, 1977. The book called Central Auditory Dysfunction is edited by Robert W. Keith. It includes a chapter from each of the guest faculty, as well as a transcript of the panel discussions and question and answer sessions.

Speakers at the symposium pointed out the great need for normative data for tests of central auditory dysfunction and a better understanding of how the data can be applied in the remediation process. The Division of Audiology and Speech Pathology at the University of Cincinnati Medical Center is considering the possibility of follow-up symposium to deal with the area of remediation.

AAS to Honor Hallowell Davis

The 1977 AAS Carhart Memorial Lectureship Award has been given to Hallowell Davis, M.D., who will present the lecture in Miami at the December 12th meeting. No more appropriate recipient could be selected for this award than Dr. Davis. He exemplifies the high principles of scientific inquiry that Ray Carhart also represented. He was a friend and often-time associate of Ray Carhart in many endeavors. He was one of the early workers, like Ray Carhart, in studying human hearing and its problems.

During the past few years Dr. Davis has received a great number of recognitions and awards for his long-term and continued productivity in the field. By accepting the Carhart Memorial Lectureship Dr. Davis does honor to this new and burgeoning American Audiology Society. For registration form see page two.

Exec. Committee Election Results

With the ballots from the recent election counted we are happy to announce that the following members will be appointed to the AAS Executive Committee for a four year term beginning in January, 1978.

A Bruce Graham, Ph.D., 1953, Northwestern University. Chief, Division of Audiology, Speech and Language Pathology at Henry Ford Hospital. Henry Ford Hospital, 2799 West Grand Boulevard, Detroit, Michigan 48202.

Earl Harford, Ph.D., 1958, Northwestern University; Professor of Audiology and Director of the Division of Hearing and Speech Sciences, School of Medicine, Vanderbilt University; Director, Bill Wilkerson Hearing

and Speech Center, 1114 19th Avenue, South, Nashville, Tennessee 37212

Susanne Kos, M.S., 1975, North Texas State University. Clinical Audiologist, University of Texas at Dallas Callier Center for Communication Disorders, 1966 Inwood Road, Dallas, Texas 75235.

Merle Lawrence, Ph.D., 1941 Princeton University, Professor of Otolaryngology and Director of the Kresge Hearing Research Institute, Department of Otorhinolaryngology, University of Michigan Medical School. University of Michigan Medical School, Ann Arbor, Michigan 48109.

Fred Linthicum, M.D., 1946, University of Southern California School of Medicine. Member of

Otologic Medical Group, Inc.; Director of Education and Temporal Bone Laboratories, Ear Research Institute; Clinical Professor of Otolaryngology, University of Southern California School of Medicine, 2122 West Third Street, Los Angeles, CA 90057.

Samuel F. Lybarger, B.S., 1930, Carnegie-Mellon University, Self-employed as acoustical consultant. 101 Oakwood Rd., McMurray, Pa. 15317.

W. Dixon Ward, Ph.D., 1953, Harvard. Professor, University of Minnesota. Depts. of Communication Disorders, Otolaryngology, Environmental Health, and Psychology. 2630 University One S.E., Minneapolis, Minnesota 55414.

CORTI'S ORGAN is a quarterly publication of the American Audiology Society, printed in Dallas, Texas.

W. Dixon Ward, Ph.D.
Laura Ann Wilber, Ph.D.

Ex Officio:

J. Donald Harris, Ph.D.
Marion Downs, M.A.

Editorial

An ad hoc committee headed by Dix Ward is reviewing a new Constitution and By-Laws for the AAS. This is always an onerous task, and Dix is to be congratulated for finding the energy to address himself to it. One of his best working members has been Sam Lybarger, who has also devoted a great deal of effort to the job. He has come up with a detailed critique that may make the document a sound one that will endure the future changes inherent in any dynamic group. The rest of us dunderheads on the committee haven't been much help.

The membership should also know that the name change resolution will be submitted at the same time the new constitution is presented. This delay will give us all time to reflect on whether we prefer the term Audiology or the term Auditory as representative of what we do as a group.

As the ad says, Audiologists do it in sound rooms! MPD-RJR

Notice - The Executive Committee has approved a \$5.00 increase in 1978 membership dues.

For some decades the fitting of hearing aids has been the exclusive province of dealers working either quite independently or more usually as representatives of major manufacturers. Founders or other personnel of these companies (one thinks of Fred Kranz, of the late Leland Watson, and others) often worked closely with otologists to develop models to fill demonstrated needs. This association between physicians and hearing aid dealers became and persists today as the most common system of hearing aid prescription and delivery.

Not too long ago it was possible for anyone with a good character reference and some financial resources to set up a hearing aid dealership with no professional training or expertise whatever. Hundreds of men and women have under this system become excellent hearing aid specialists by way of a variety of types of on-the-job training through professional hearing aid dealers association conventions, short courses, and magazines, through manufacturers' training materials and factory visits and always (in common with us all) through profiting from countless mistakes on past clients. There was always, of course, some highly visible fraction using advertising methods of at least doubtful ethics and whose "hard sell" approach did a disservice to many persons, and a fraction whose level of knowledge of hearing and the possible effects of amplification was abysmal.

Today the situation has improved greatly. Should a hearing-impaired person choose to obtain the services of a certified member of the National Hearing Aid Society, that dealer would at least be no neophyte but would have had a minimum of 2 yrs supervised practice in fitting hearing aids and have passed a national examination. Many states have certification which tends to weed out the incompetent and unethical. Although many dealers who could perhaps be shown incompetent are "grandfathered" in at the moment, this proportion will decrease steadily. Today there are many avenues, including a 2-yr college Associate degree, by which a person can learn hearing aid dispensing or can pursue continuing education.

Despite these developments, the current state of affairs is far less than desirable. Many laymen, recalling past incidents or meeting new evidence, hold hearing aid dealers in suspicion. Too many a hearing-impaired person is improperly fitted, either because the ideal aid for that person has not yet been invented, or because the dispenser has an imperfect knowledge of (1) the state of the client's hearing and/or (2) the best prosthesis within those many options currently available.

The relation between the ear doctor (otologist or otolaryngologist) and the hearing aid dealer has often been of great benefit to the patient, and no other member of the hearing health delivery team could have contributed significantly. But in many cases the services of a third professional,

usually an audiologist, has been, or would have been, vital:

(1) Frequently a hearing-impaired patient is told by an ear doctor that his hearing loss is uncorrectable because it is a "nerve loss." In all too many cases the physician states that the patient might try a hearing aid but that most likely it would not help; the physician might even predict that a hearing aid would not help. This kind of advice, without a full audiological workup, is unfortunate and reflects the fact that many physicians are simply not aware of the real advances which have been made in audiological examination and in current hearing aid technology. In such cases of hard-to-fit clients, consultation would be vital between the physician and an audiologist well versed in all aspects of audiological testing and hearing aid evaluation. Modern professional audiological literature contains numerous cases of one of the newer prosthetic systems enabling a person to communicate who was unable to profit from one or more earlier models.

(2) Frequently also, a large fraction of hearing-impaired persons need more, perhaps far more, than simply a good prosthesis such as a competent hearing aid dealer might provide. With children of all ages from neonates to teen-agers it is clear that habilitation and rehabilitation techniques must build upon, but go far beyond, provision for appropriate amplification. The special audiological needs of geriatric patients in addition to amplification are being emphasized. For some adults with sensorineural loss very special requirements may need to be met to allow reasonable communications. Even for adults with no over-riding problems except diminished hearing it is frequently necessary to do more than simply encourage the client to wear the aid and not tuck it away in a drawer, as any salesperson might do.

We are approaching here the question of the limits of training and expertise of the hearing aid dealer. He is by FTC regulation now expected to direct his client to an ear doctor if he detects any of certain "medical alert" symptoms. But there is still an area of "audiologic alert" symptoms on the detection of which the dealer should be expected to direct his client to an audiologist certified in the management of communicative disorders due to hearing impairments.

It seems clear then that audiologists have carved out for themselves an advisable and in many cases an indispensable role in creating or revising communication skills in the hearing-impaired person of any age.

One difficult question in this emerging picture of the physician-audiologist-dispenser team is the relation of the newest member, the audiologist, to the other two. Some audiologists in medical settings are contributing substantially to medical diagnosis, the exclusive province of the physician. It is, however, possible to speak of a communicative dysfunction arising from hypacu-

sis, with diagnosis and treatment the province of the audiologist; in this case a prosthesis may be simply one of the tools in the audiologist's bag. Some audiologists in private settings, often in association with physicians, may undergo the same training and adopt the same financial posture as the traditional commercial hearing aid dealer and seek a license themselves to dispense prostheses. Some audiologists in public settings may perform hearing aid evaluations and either refer their patient to a commercial dealer or dispense aids under the aegis of their clinic.

In these diverse settings, some strains among members of the hearing health delivery team are inevitable. The physician is uneasy at the audiologist entering the area of diagnosis of any sort. The audiologist may attempt to direct very precisely the fitting of a prosthesis by the dealer even though he may never have fitted a hearing aid and his "hearing aid evaluation" is marked by uncertainty. As Pollack (1975, P. 145) says "If you were to bring 10 clinical audiologists together to discuss the hearing aid selection procedures they use with adults, you would inevitably hear 10 different approaches... Unfortunately, with the present state of the art and the clinical tools available, no one procedure may be superior to the others."

There are, however, some signs of hope on the emerging scene. After far too long a time, ASHA has seen that clinical audiologists, in order to best serve certain clients and even whole subpopulations, must involve themselves in actually tailoring prostheses to individual ears in

the traditional manner of commercial hearing aid dealers. Fortunately this service, with its precious ingredient, feedback, is no longer seen by ASHA as crass commercialism but as a vital professional activity which enhances rather than detracts from the professional image of audiology. On an even broader scale national governmental bodies have held lengthy public debates on the prosthesis and its delivery system, and cool heads are pointing to the advisability - the necessity of cooperation among all members of the team. It is no longer tolerable for factions to wobble about images and egos. Roles are rapidly changing now and will change in the future, but these changes will significantly help the hearing-impaired if those involved keep the real problems in focus. There is still much to be learned about evaluation of candidates for hearing aids, and in the techniques of fitting. Moreover, the industry is creating new principles and models at a breathtaking pace. Still 82 per cent of those who need a hearing aid are not wearing one and remain in a world of less than maximum communications. It is encouraging to see the many scientists, engineers, and professional persons of all sorts who have now become concerned, and these will ignore with justified contempt the personalities, prejudices, egos, or images which should in any way compromise the help desperately needed by so many.

Gerber Home Destroyed by Fire

The Santa Barbara fire caught the home of Sandy Gerber, SENTAC prexy, and gutted it completely. What was once a beautiful new house, burned to the ground by the fire that ravaged a large residential area of Santa Barbara.

Fortunately Sandy, his wife and

children, were away from home but his wife came back in time to see it reduced to ashes. Ironically they had just recently built the house and moved in. But Sandy adopts a fatalistic attitude and seem quite unruffled by the experience. He left for a trip to Israel a week after the fire.

News About Members & Others

Alice Berkowitz has accepted the newly created position of Regional Director of Professional Services with Audiotone, Inc. She leaves a position as Director of Audiological and Speech Services at Manhattan Eye, Ear and Throat Hospital in New York City.

Harvey Firestone, Lt. (J.G.), U.S. Coast Guard, has established a Hearing Conservation program

for the Coast Guard. He is making a film to educate commanding officers about the program.

Gilbert Herer is newly elected President of the Maryland Speech and Hearing Association for 1977-78, and was appointed for a three-year term to the Noise Control Advisory Board of Montgomery County, Maryland.

Address _____

THE INTERROGATORY

Corti's Organ has invited a group of knowledgeable Audiologists to address themselves to the question:

"What are the implications for hearing problems in infants and children with recurrent serous otitis media, and how do you handle them?"

Anne Seltz, CCC-A, Audiologist, St. Louis Park Medical Center, Minneapolis.

Because of auditory input human infants and children acquire healthy language and speech. Because of adequate BINAURAL auditory input humans learn to define spacial relationships. Because of NON-VARIABLE hearing humans develop a stable and precise auditory processing competency. Reduced auditory input due to hearing loss, monaural or binaural, interferes with the human communication process. Less than normal intelligence, less than normal social and emotional development, and less than normal health negatively affect a person's use of auditory input. Communication and listening needs vary with age, educational status, employment environment, social environment and personality.

The Down's Syndrome young child with chronic middle ear disease and probable continued reduced hearing over time in combination with expected reduced intellectual function cannot tolerate reduced hearing to as great a degree and for as long a time as can a bright, emotionally stable, assertive ten-year-old child who has the ability to define changes in his auditory input. The nine-month-old child passing through a very critical language acquisition period cannot tolerate two months of reduced hearing without an effect on that developmental process. A young adult working in a nonverbal environment with minimal verbal social behaviors can tolerate reduced hearing for longer periods of time than can a fulltime mother, a verbal sales clerk, or a courtroom stenographer. A primary physician whose major professional communication is on a one-to-one basis can tolerate a greater degree of hearing loss for a longer time than can a classroom teacher or a student in a classroom.

Any adult can tolerate a greater degree of hearing loss for a period of time than can any child of any age because any child is acquiring speech, language, and general knowledge while any adult has usually completed those processes.

Multiply-handicapped children are in greater need of good auditory input than are persons without disabilities and they should receive the most aggressive medical and audiological intervention.

As an audiologist in a multi-disciplinary health care setting with 100 physicians including three otolaryngologists, ten family practice physicians, ten pediatricians, three allergists, and two pediatric nurse associates, I receive many varied requests for evaluation of children. In addition,

I receive requests for evaluations from school personnel, parents, and other health care professionals outside this Center. By far the majority of children I see have middle ear dysfunction, history of middle ear dysfunction, or history of delayed speech and language development. I define monaural hearing status, child's ability to use auditory system for purposes of communication and speech and language development, the stability of this hearing ability over time, the child's ability to tolerate reduced hearing for a period of time without significant effect, the ability of the family to compensate for any amount of reduced hearing by bringing child closer and talking louder, and interpret my data and recommendations to the parents and involved health care professionals and/or school personnel.

If medical management cannot maintain healthy ears or near normal hearing I recommend amplification to the family as a viable option. I do not agree with the opinion that medical management must precede audiological intervention with use of amplification. The variables of duration of hearing loss, pattern of hearing loss, variability of hearing loss, age of child, and ability to tolerate reduced hearing must be considered by the audiologist. If medical management of middle ear disease requires more than two months of medication and/or surgical intervention and chances for maintaining normal hearing with this regime are not excellent, then audiological management with amplification will be considered. Too often audiological management is not requested until the physician has successfully eradicated the disease process. In some cases this can be months and years. The audiologist can be aggressive in defining the need for normal hearing in the pediatric population, can monitor hearing over time in the chronic population, can provide on-going consultation and counseling to parents of this population, can make appropriate referrals to speech pathologists for evaluation, preventive counseling and treatment, and can aggressively use amplification when that is a viable alternative or additive for maintaining near normal hearing binaurally.

In order to access these variables the audiologist needs to become involved in primary care of middle ear disease by providing guidelines to primary physicians and by seeing all children under the age of 8 in the ENT office. Audiometricians can see the adults. In my office audiometricians do not see children because they can only measure. Most otolaryngologists do not profess to be knowledgeable in child development, speech and language development, management of the acoustic environment, and do not communicate as effectively with parents and schools and speech pathologists about these subjects as do audiologists.

Audiologists are uniquely prepared to evaluate the effect of any degree of hearing loss on a particular child or a particular

age in a particular environment with a particular history. They are uniquely prepared to evaluate the effect of hearing loss in conjunction with other disabilities. The cooperative decision making and treatment by the audiologist and the physician can be especially effective in management of the infant and child with otitis media for purposes of maintaining near normal binaural hearing.

Thomas J. Fria Director, Audiology, Children's Hospital of Pittsburgh.

The implications of hearing loss in infants and children with recurrent serous otitis media can be significant when viewed in the context of eventual speech and language acquisition. Although the hearing loss associated with serous otitis media can be considered mild and in most cases, transient, the situation for recurrent serous otitis media is somewhat different. Recurrent serous otitis media results in fluctuating mild conductive hearing loss throughout several months of the child's life. Most frequently this bout of recurrent otitis media occurs between the ages of 2 and 8 years, at a time when speech and language acquisition is quite active.

Consequently a fluctuating mild conductive hearing loss in a time of active speech and language acquisition can have serious implications for the child involved. At the very least, he or she may face confusion when attempting to use subtle auditory information for language concept formation and accurate articulation patterns.

Documentation of the effects of fluctuating conductive hearing loss on the acquisition of speech and language has until recently been unavailable. Very few organized studies of these effects have transpired. In 1969, Holm and Kunze studied the effects of serous otitis media on language and speech development and found that children with chronic otitis media were significantly deficient in tasks requiring reception and integration of auditory information. They were also deficient in the production of verbal responses. The authors found deficiencies which covered a large range of linguistic skills. For example, articulation of speech sound in single words, receptive vocabulary as measured by the Peabody Picture Vocabulary Test, the use of analogies (both visual and verbal), grammatical structures and the ability to repeat digital sequences.

In 1977, Needleman and Menyuk studied the effects of fluctuating conductive hearing loss on a single facet of language: the comprehension and production of aspects of the phonologic system. Subjects with history of recurrent serous otitis media were found to be deficient in total phonologic performance, production of phonemes in words, and connective speech, and the use of combinations of phonemes in word endings. Hence, the 3 to 8 year old children studied by

Needleman and Menyuk were found to have significantly deficient phonologic abilities when compared to suitable controls. The authors point out that such phonologic abilities are prerequisites for learning to read and that deficiencies in this area can perhaps account for the educational retardation observed in children with recurrent otitis media.

As additional organized investigations of the effects of serous otitis media on language acquisition are performed it will no doubt become increasingly apparent that mild transitory hearing loss secondary to recurrent otitis media can have serious implications for the children involved. Once we recognize that such implications exist, we must go a step further in the management of these children. For example, all individuals involved in the education of the child should be informed of the deleterious effects a mild conductive hearing loss can have on the development of the child. Such individuals would include parents, educators and professionals. The concerned individuals must be made aware of the need to carefully monitor the degree of hearing loss throughout the course of recurrent serous otitis and in some way they must establish an environmental flexibility which can align itself with the child's needs during the course of the disease.

One possible role for the audiologist is that of patient advocate. In other words, he or she should be concerned with the regular and accurate monitoring of hearing levels in the child with recurrent otitis media and he or she should work actively to establish a liaison with the individuals concerned with the child's education. In summary, I can only say that we must all recognize that the mild conductive hearing loss associated with serous otitis media can no longer be overlooked as having implications for the child's eventual language development. This is particularly true in the case of recurrent serous otitis media and appropriate measures must be incorporated by all individuals concerned with the child's welfare.

R. Ray Battin, Director The Battin Clinic, Houston, Texas:

Howie, Downs, and others documented lower verbal intelligence in children with a history of recurrent otitis media during infancy and the primary years. Clinically, we have been documenting the test profiles and behavior of children with learning problems with a history of early and recurrent Serous Otitis Media. These children were labeled by their teachers as troublemakers, daydreamers, and non-cooperative. They were described as inattentive, distractible, and as having short attention spans. Testing revealed these children had difficulty processing information received through hearing. They had not developed the ability to selectively attend and could not function when competing noises were present. As a result they were unduly punished by the open

concept school program. If in the traditional classroom, they failed to get the teachers instructions unless seated on the front row. They did poorly in classroom activity that demanded group participation or in rooms with a high noise level.

Failure to develop auditory retention and storage skills prohibited these children from hanging on to information long enough to process it. Since reading is primarily an auditory skill, reading level is significantly depressed.

Failure to develop the ability to auditorily synthesize or close out the message further impedes the ability to process the incoming message and these children acquire the label of refusing to conform, smart alecs, can't follow directions.

As a result of these auditory language processing deficits, these children not only are in trouble in school, but with their peer group as well.

If we look at statistics some amazing similarities occur. The National Academy of Sciences reports an incidence of 30 percent with normal or above intelligence have a language/ learning disability. One out of ten students nearing the end of high school cannot perform basic, everyday reading tasks. Freeman has found juvenile delinquents trace their initial acts of crime back to when they dropped out of school because they were slower than

[Cont. on Page 6]

News Release

The Board of Directors of Environmental Hearing and Vision Consultants, Ltd. of Syracuse, New York, has announced the formation of Environmental Health Screening Services, Inc. The president of Environmental Hearing and Vision Consultants, Ltd., Dr. Alan Feldman, notes that the new division will provide full health screening services, on-site, through the use of a mobile clinic. Mr. Walter Curry, Program Director, stated that this new service received its impetus from the acquisition of a multi-year contract with a large northeastern utility company. The contract calls for the provision of a wide range of OSHA required health screening services to a large number of the utility's employees.

The mobile clinic, staffed by professionals, will offer chest x-rays, pulmonary function tests, EKG, blood profiles, urinalysis, vital signs, and other special services as may be required. Initial plans are for the Syracuse based consulting firm to offer this new service in the northeast. According to Mr. Curry, the incentive for developing a complete health screening program arose from inquiries from present clients who already have Hearing Conservation Programs operated by Environmental Hearing and Vision Consultants, Ltd. The need to provide on-site health screening is growing as Federal health standards are developed to meet a wide variety of industrial hazards.

Corti's Editor Honored by SENTAC

The Society for Ear, Nose and Throat Advances in Children (SENTAC) has chosen Ye Editor Marion Downs as its first Honor Guest at the 1977 annual meeting in Chicago, October 29-November 1. Downs will give the Honor address at the society's banquet October 29, presenting a talk on "Childhood — Son et Lumière".

The main program of the meeting will include the following: Meningitis: A Case for Multidisciplinary Management (Papaz); Otologic and Audiometric Findings in Cystic Fibrosis (Abramson, Franco); Pediatric Epistaxis (Jafek, Wong, Balkany); Voice Speech and Language Habilitation in Young Children Without Laryngeal Function (Kaslon, Grabo, Ruben); Unilateral Sensorineural Hearing Loss in Child-

ren (Bergstrom, Shallit); Hearing and Speech Assessment in Noonan's Syndrome (Gerber, Hopkins); Rubinstein-Taybi Syndrome — Otolaryngic Manifestations, A Case Report of Respiratory Obstruction (Isaacson, Remoanczuk, Potsic); Bacterial Meningitis & Hearing Loss, A Prospective Pilot Study (Berlow, Caldarelli); Effects of Noise on Children's Speech Perception (Elliot); The Effects of Noise on Young Children (Bess, Finlayson); Central Auditory Testing with Children: One Audiologist's Experiences (Del Polito); Misfirings of F.M. Auditory Training Systems (Hood, Boyden). Current Developments in Physiological Measures of Hearing in Children — Laszlo Stein, Ph.D., Moderator. Auditory Screening with High-Risk Neo-

nates: A Four-Year Study (Meyer); Utilizing Early Evoked Response to Screen Hearing in Newborns (Hamilton); Acoustic Reflex Measures for the Prediction of Hearing Sensitivity in Retarded Children (Zarnoch); Recent Developments in Electrophysiological Testing (Ear) (Mendel); Stridor in the Neonates, Infants and Child (Holinger); Tracheotomy in Infants (Wong); Neonatal Tracheotomy (Seid); Pediatric Endoscopy Use of the Storz-Hopkins System (Reichert); Traumatic Pseudodiverticulum in the Neonate (Gibson). Study of Pharyngeal Airway in the Children with Obstructive Hypersomnia Sleep-Apnea Syndrome Secondary to Adenoidal and Tonsillar Hypertrophy (Borowiecki); Otolaryngologic

Aspects of Immune Deficiency States (Kimmelman, Potsic, Caleb, South); The Nasopharyngeal Culture: A Reappraisal of its Usefulness in Otitis Media (Schwartz, Rodriguez, Mann, Khan, Ross); Nasopharyngeal Obstruction: Diagnosis and Management (Levine, Batza); Hearing Loss in Children of a Pre-industrial Society (Deutch); Vestibular Responses in Infants: Trends Over Time and Correlation with Gestational Maturity and Weight at Birth (L. and A. Eviatar); Electroacoustic Tympanometric Measures Obtained with Children (Chermark, Luchini). ENT - Speech Voice Panel, Doctors Richardson (moderator), Hart, Cotton, Scott and Pannbacker. Didactic Panel-Eustachian Tube Testing (Seidemann and Seiffert).

When QUIET is Important!

Precise audiometric measurements require quiet . . . the complete QUIET that comes with TRACOUSTICS Audiometric Examination Rooms and Suites.

TRACOUSTICS offers complete flexibility in planning your single or double wall Audiometric Examination Room or Suite with flush magnetic sealed

doors, carpeted floors; recessed lighting fixtures, and hidden electrical wiring.

TRACOUSTICS' qualified representatives will help plan your facilities and insure that they are promptly and properly installed. Call us collect for the name of our closest representative.

Book Reviews

CARMEN, RICHARD. OUR ENDANGERED HEARING: UNDERSTANDING AND COPING WITH HEARING LOSS. Emmaus, Pa.: Rodale Press, Inc. (1977). 224pp. \$7.95.

Reviewed by Todd H. Porter, Director of Audiology, Houston Ear, Nose and Throat Hospital Clinic, Houston, Texas.

In **OUR ENDANGERED HEARING**, Audiologist Richard Carmen has provided the hearing-impaired with a well-written, factual and easy-to-read discussion of many aspects of hearing loss. The initial chapters deal with the incidence of hearing loss, the psychological impact of hearing loss and the effects of hearing loss on communication ability. Many of the myths associated with hearing loss are dispelled and the author provides the reader with an insightful discussion of the everyday problems encountered by the hearing-impaired as well as offering practical advice on coping with a hearing loss. An entire chapter is devoted to a convincing, although in the opinion of this reviewer somewhat over-stated, indictment of environmental noise exposure as the major cause of hearing loss in today's society. The statistics presented are, however, alarming.

In other segments, the mechanism of hearing is discussed along with the various causes of hearing loss, types of hearing loss and treatments available for certain types of hearing disorders. Much of the remainder of the text deals directly with the practical consid-

erations involved in hearing aids - how to choose an aid, the procedures that should be followed in obtaining an aid, the social and psychological ramifications of wearing an aid, what may be realistically expected from an aid, the costs involved, etc. The author also offers practical consumer protection advice and goes to great lengths to warn against sales abuses that may be avoided by otological and audiological consultation and evaluation prior to the purchase of a hearing aid.

Special features include a question/answer section with many common (and some not-so-common) questions regarding hearing loss and a presentation of several case histories relating personal experiences with hearing loss. The appendices offer sources of information relating to hearing loss, noise abatement, consumer protection, hearing aids, telephone and television aids, and a listing of potentially ototoxic drugs.

OUR ENDANGERED HEARING should be very helpful in assisting the hearing-impaired to understand the problems associated with their hearing loss as well as coping with their hearing loss. It should also be particularly helpful for the family and other associates of persons with hearing loss, and I would not hesitate to recommend it to my patients. In addition, Audiologists and others involved either directly or indirectly with the profession of Audiology will find this book beneficial in counseling the hearing-impaired and their families.

3:35 - 5:18 p.m. Contributed Papers
5:19 pm - 'til Brief Business Meeting
8:30 p.m. - 'til Dinner with Hallowell Davis

Program Chairman: Harris L. Pomerantz, 515 Bay Street, Tampa, Florida 33606

INVITED PAPERS

2:15 - 2:40 p.m. Altitude Effects on the Aviator. Donald C. Gasaway, U.S.A.F. School of Aerospace Medicine Brooks Air Force base, Texas
2:40 - 3:05 p.m. Diving Hazards: Round Window Membrane Rupture A Cause of Sudden Deafness. Frederick W. Pullen Miami, Florida
3:05 - 3:30 p.m. Congenital Mixed Deafness; Perilymphatic Hydrops. J. Brown Farrior, Tampa, Florida.

CONTRIBUTED PAPERS

3:35 - 3:47 p.m. Use of a Central Auditory Processing Test Battery in Evaluating Residual effects of Decompression Sickness. Gerald Miltenberger, Vincent Caruso, Manning Correia, J. Thom Love, and Paul Winkelmann, Galveston, Texas.
3:48-4:00 p.m. Eustachian Tube Testing Normative Data in Children. Michael F. Seidemann, and Gregg Givens, New Orleans, Louisiana.
4:01-4:13 p.m. A Systematic Study of the Effects of Direction and Amount of Pressure in Eustachian Tube Testing in Adults. Michael F. Seidemann, Gregg Givens, and Melinda Seifert, New Orleans, Louisiana
4:14 - 4:26 p.m. Audiologic and Metabolic Findings in Patients with Fluctuant Hearing Loss. Paul Yanick, Jr., and Stephen Freifield, Summit, New Jersey.
4:27 - 4:39 p.m. Comparisons Among Auditory Reaction Time, Loudness and Certain Characteristics of the Acoustic Reflex. Lynne Marshall, and John F. Brandt, Lawrence, Kansas.
4:40 - 4:52 p.m. The Effect of Pressure on Pure Tone Thresholds. Thomas W. Norris, Robert E. Jirsa, and Barbara K. Skinner, Omaha, Nebraska.
4:53-5:05 p.m. Development of a modified Speech Discrimination Test. Glen Bull, Linda Kirwin, Roger Ruth, and Zahrl Schoeny.
5:06 - 5:18 p.m. The Effects of Asymptotic Noise Exposure on a Battery of Tests. Gordon Blenvenue, Thomas Bennett, Adam Anthony, and Paul Michael, University Park, Pennsylvania.

Gallaudet College Opens Extension Center in Midwest

Washington, D.C. -- Gallaudet College, the world's only accredited liberal arts college for deaf students, has established an Extension Center far from its campus in Washington, D.C. In cooperation with Johnson County Community College in Overland Park, Kansas, a suburb of Kansas City, the Center for Continuing Education of the national college for the deaf is extending the services which it can provide to deaf individuals, their families, and professionals who work with deaf people to the five state midwest region of Kansas, Missouri, Oklahoma, Iowa, and Nebraska.

Explaining this move to open the Midwest Regional Extension Center at Johnson County Community College (JCCC), Dr. Thomas Mayes, dean of Gallaudet's Center for Continuing Education said, "Requests for the exportation of services from Gallaudet College came from institutions and agencies in many parts of the country and in increasing numbers, but because of the location of Gallaudet in the nation's capital the Eastern seaboard area received the greatest

attention. Johnson County Community College, located in the geographic center of the five-state midwest region, has an exemplary postsecondary program for the hearing impaired and has demonstrated a desire to expand its services for the handicapped. With the new Center," he continued, "we can expect to plan and schedule each year a variety of workshops, short term training programs, seminars, and other learning activities, drawing not only from the staff and faculty of Gallaudet College but also from appropriate resource persons from schools for the deaf, colleges and universities including JCCC, and state and local agencies in the area for the conduct of such programs."

"What we're talking about," said Edward Franklin, newly appointed director of the Extension Center is a pilot program for Gallaudet, which is attempting to serve a wider geographical portion of the country.

Franklin, who comes to his new position from counseling hearing impaired students at the Metropolitan Technical Community College in Omaha, Nebraska, has

been working with deaf people in various capacities for the past five years. He believes that there is no limit to the number of people in the five-state region who could be served by the Extension Center. We're starting now to plan workshops for as early as the last part of October, he said.

Programs which may be offered by the Center include intensive workshops in language development for elementary teachers, region-wide certification for teachers of sign language, courses in leadership for deaf adults, parent education sessions, P.L. 94-142 workshops, and professional workshops. Both Franklin and Mayes anticipate that the Extension Center will try to meet some of the educational, vocational, cultural, and social needs of deaf children, youths, and adults as they are identified by schools and agencies in the five-state region.

For more information contact: Dr. Thomas Mayes, Dean, Center for Continuing Education, Gallaudet College, Washington, D.C. 20002, or Edward Franklin, Director, Midwest Regional Extension Center, Johnson County Community College, Overland Park, Kansas 66210.

OSHA Drops Feasibility Document

OSHA spokesman Morton Corn announced a decision to discontinue development of a technical feasibility document on noise control. A draft document, prepared under contract by Bolt, Beranek and Newman, Inc., became too much of a point of controversy during the hearing on workplace standard revisions. It was also being prematurely used by OSHA compliance officers for enforcement purposes.

A number of industries responded to the Labor Department's request for comments on the BBN document. The industries said the document left doubts about its economic analysis of workplace noise regulation, and they questioned the cost figures and worker exposure profiles.

EPA also remained unsatisfied with the document. They stated that the acceptance by BBN of the AAOO's definition of hearing impairment is in question, as it was not intended for use in preventive criteria. EPA was also dissatisfied with the report's treatment of worker mobility.

CHABA Will Look at Noise and Electro-Physiology

The Committee on Hearing, Bioacoustics and Biomechanics ("CHABA") of the National Research Council will cover noise and other topics at its meeting October 20 and 21 in Washington, D.C. Secretary Milton Whitcomb announces that the meeting will cover the following areas:

1. The Concorde Trail at Dallas.
2. The Status of Voiceprints in the Courtroom.
3. Direct Electrical Stimulation of the Auditory Nervous System.
4. Auditory Evoked Potentials.
5. The Effect of Noise on Sleep.
6. Problems of High Intensity Noise.
7. The Effect of Whole-Body Vibration.

This CHABA meeting is back-to-back with the NOISE-CON 77 meeting being held October 17-19 at NASA Langley nearby, so members may combine the two meetings.

Interrogatory . . .

[Cont. from Page 3]

other students or else disruptive. 75 percent of the potential drop-outs have identified themselves by the time they are in fourth grade. Language learning problems, particularly those arising from auditory processing deficits generally manifest themselves in the third or fourth grade. The Colorado Youth Services report 80 percent of incarcerated juveniles have language learning disabilities.

Recurrent serous otitis media in the infant does not mean the child necessarily will become a juvenile delinquent. It does mean there is a high risk factor that he will fail to develop normal auditory-language processing skills and thus become language-learning disabled. This sets the stage for moving into the delinquent population.

Webster and Webster documented that rats who were given conductive hearing losses at birth developed significantly smaller globular cells of the ventral cochlear nucleus and neurons of the medial nucleus of the trapezoid body than a normal matched group when neuronal comparisons were made at six weeks. There were also fewer neurons in the dorsal cochlear nucleus. These nuclei are located in the brain stem and are integrally associated with the reticular activating system which is important in establishing and maintaining cortical tone.

The maintenance of cortical tone is crucial to the maintenance of attention. Sheer maintains that hyperactivity and the accompanying distractibility is the result of the organism's attempt to increase cortical tone via sensory stimulation as a result of inadequate brain stem activation of the cortex. It is logical to assume that during early critical stages of development, mild sensory deprivation due to conductive hearing loss resulting from serous otitis media has the potential to cause the symptom that is referred to as Language Learning Disability.

All professionals who treat or evaluate the infant and preschool child must be aware of the developmental ramifications of mild conductive hearing loss. Prevention of later auditory-language processing disturbance through aggressive treatment is critical. It will only come from early identification and aggressive treatment. The latter requires cooperative effort between the physician, the audiologist and the clinician. Once identified, mild amplification should be utilized if medical treatment cannot control the hearing. Losses averaging amplification should be utilized if medical treatment cannot control the hearing. Loss averaging greater than 15dB should be fit with a mild hearing aid. Parents should be trained to provide proper auditory training to stimulate the development of auditory decoding, synthesis, figure-ground and retention skills. This home program should be monitored by the audiologist or hearing clinician and modified as needed. If the youngster is 3 years or older, consideration should be given to placing the child in a formal treatment program coupled with a strong home program.

Auditory-language processing skills can be remediated in the school age child. It is a long treatment program which must direct itself not only to the auditory problems but to the resulting academic and emotional problems. How much better it would be to concentrate our efforts on prevention.

Noel D. Matkin, *Pediatric Audiologist, Director, Language & Learning Center, Boys Town Institute for Communication Disorders in Children, Omaha.*

While serous otitis media is widely viewed as a common childhood problem, there are at least three major reasons why the implications of middle ear effusion on language development and auditory learning during infancy and early childhood have not been appreciated. First, middle ear effusion typically has not been viewed as a basis for communication disorder since many cases readily respond to medical or surgical intervention. Yet, a longitudinal study by Kaaijk (1977) indicated that 7 percent of the children with temporary hearing loss evidenced 4 or more episodes of otitis media over time with 29 percent of these youngsters having a bilateral impairment. In other words, a significant number of youngsters repeatedly encountered periods during which hearing sensitivity is depressed in both ears. Second, the pervasive effects of a so-called "mild" bilateral hearing loss during childhood, whether the impairment is conductive or sensorineural in type, have not been recognized. However, a review of the hierarchy of language development suggests that the rapid acquisition of receptive language concepts and associated auditory learning skills during the preschool years serves as the foundation for subsequent success in academic achievement once a youngster enters a school program. As McCarthy (1954) succinctly states "The child whose language development is seriously

ly delayed for any reason labors under an almost insurmountable handicap in his social and academic relationships". An investigation in the public schools by Quigley, et. al., (1969) as well as clinical experience, has revealed that minimal losses of 25-30dB often result in language delays of one or more years. Further, the handicap becomes more evident as the degree of the loss increases; with delays of 3 and 4 years commonly encountered in the presence of a 50dB bilateral impairment. Third, while articles are scattered throughout various journals which substantiate the preceding comments, adequate longitudinal research with large samples of young children having well documented medical histories and multi-disciplinary psychoeducational evaluations is lacking. Consequently, definitive information is not available with chronic serous otitis media and such issues as: the effectiveness that language and learning deficits associated with bilateral conductive losses can be remediated; the preferred remediation ear pathology during the first two years of life. Downs extrapolated from this data that 15 percent of all children, birth to two years of age, would have significant hearing loss. 15 percent to 20 percent of children in the regular classroom plan including use of amplification with fluctuating hearing loss; the effect of a unilateral hearing loss during early childhood; the prevalence of sensorineural deficits secondary to chronic SOM; etc.

The need for coordinated team work involving, as a minimum, the otologist, the audiologist and the childhood language specialist is self-evident when developing a service delivery model for children with recurrent serous otitis media. While the physician is the obvious team coordinator in such cases, the importance of ongoing audiologic monitoring and language assessment, as well as comprehensive otologic care, cannot be overstated. Simultaneously, individualized education and guidance programs for parents, as well as for educators involved in the child's management, are mandatory so that the hidden implications of the condition on present development as well as future achievement is fully recognized.

While the preceding comments relate to the management of individual children, a major educational thrust is needed in medical and educational communities regarding the potential problems resulting from middle ear effusion during infancy and early childhood. If the deleterious effects of chronic serous otitis media are to be minimized, the critical importance of early identification, referral and management must be understood by family physicians, pediatricians, nurses, nursery school teachers and Head Start personnel, among others. Obviously, such inservice training should be based on data obtained from systematic clinical investigations of children rather than upon assorted case studies so that the implications of serous otitis media are neither understressed nor overstated.

SOM is unquestionably the major cause of hearing impairment in the preschool and school aged population and is responsible for enormous and frequently irreversible social and educational retardation. Since the average hearing level of children with these conditions is approximately 14 dB, they easily "pass through" typical screening programs which use a 20-25 dB cutoff point for air conduction signals. Children with these conditions are not constitutionally "sick" in the usual sense and are usually attending school but experiencing varying degrees of difficulty in participating in classroom activities. A fluctuating conductive hearing impairment is the main symptom of the initial stage of these conditions. Impedance audiometry must be performed routinely at least on the "high risk" population if these problems are to be detected with any degree of accuracy.

Failure to identify and manage current SOM results in these children being mislabeled as having "behavior" and "learning" problems. A child with recurrent SOM and its attendant sequelae who is not correctly identified and properly treated does indeed become "learning disabled."

Inadequately treated SOM may cause irreversible sensorineural hearing impairment. Many children with recurrent SOM show severe delay in acquisition of reading and arithmetic skills. The degree of academic delay seems to be related to the severity of the hearing impairment and while the conductive component if detected early enough is reversible, the academic impairment is often not. While considerable attention has been directed to the medical complications of SOM—atelectatic middle ear, adhesive otitis media, malfunctioning Eustachian tube and cholesteatoma—hearing health professionals need to be equally concerned with the social, behavioral and academic consequences—which can have devastating effects on the development and achievement potential of the child.

The otolaryngologist is the pivotal professional responsible for definitive management of infants and children with recurrent SOM. Medical and more often surgical treatment of these conditions including adenoidectomy, myringotomy and insertion of tubes using the operating microscope must be performed promptly—not after the condition has been present for years. My role as an Audiologist is in identifying

and measuring these conditions often in essentially asymptomatic children, getting the child to the otolaryngologist for definitive treatment and measuring the response to therapy. My reading of the educational and social consequences of inadequately treated SOM leads me to support aggressive surgical management by an experienced pediatric otolaryngologist. When my patients with these conditions do originate with the otolaryngologist, I do everything possible to arrange for such a referral as quickly as possible. SOM means much more to me than a pathological middle ear. Effective treatment can forestall irreversible social and academic damage.

Patricia Heffernan, Otolaryngologist, group Medical Clinic, In Beverly Hills, California.

The relatively high incidence of otitis media in young children and its usually mild medical implications, could easily lead to the misconception that it is an innocuous problem. Many specialists believe that in the infant and young child age group much as 23 percent of the population will have otitis media.

However, I do not believe that can any longer satisfy ourselves that it is a benign problem whose only significance is possible medical complication. Nor may we look at the numbers on an audiogram and label the results significant.

Public school classes for the child with language disorders report that the medical histories of the youngsters contain an unusually high number of upper respiratory infections and middle ear disease. Only infrequently do they note significant hearing loss. Several recent studies have documented the serious delay in language and speech development and deviant auditory behavior of these children—especially in contrast to those where no such incidence is noted.

A child's development of linguistic and learning competence appears to be highly dependent on consistent sensory stimulation. Those who are already disadvantaged (socially, economically, intellectually, physically, emotionally, or any combination of these), are probably the least capable of compensating for added handicap arising from auditory inefficiency.

Parents need to be educated to recognize when their child's language and/or speech are developing in a manner that interferes with communication. The classroom teacher and parent need to have at least enough dialogue that parents can be alerted when a child is beginning to show listening and learning problems in the classroom. The physician and parents need to discuss more than the amount, schedule of medications, and possible diagnoses. We are beginning to accept that behavioral information is more meaningful than falling into the routine of offering a diagnosis (usually in terms that parents cannot understand).

If a child is in the years critical to developing mastery of his language and speech patterns (under age 3½), his parents should be alerted that he may need to be held in mother's arms for language.

age stimulation, since this provides him with increased insensitivity for her voice. Parents should be alerted to watch for delay in language and/ or speech. If combining factors or developmental language and/ or speech impairment, and otitis media occur, the child should have continuing and consistent medical monitoring until the ear is functioning normally; (b) regularly scheduled audiologic evaluation - to include Impedance testing, as well as audiometric threshold measurement; and assistance from a speech pathologist knowledgeable in normal patterns of language speech development, and appropriate intervention techniques.

The school age child with continuing middle ear disease, regardless of the degree of hearing loss should have any of the above found necessary, - plus - a continuing communication system between the non-school and school personnel responsible for youngster's medical care, educational progress.

Otitis media is educational potentially dangerous disability deserving urgent intervention. Not all children who suffer middle ear disorders will sustain language and/ or learning difficulties. However, we lack the tools to identify those who will. Many of those who do develop problems may escape identification until their deficits are too long established to respond easily to rehabilitation attempts.

New By-Laws Proposed

Dix Ward, as chairman of the Committee on By-Laws Revision, presented the new document to the Executive Committee at the Miami meeting. The Executive Committee voted unanimously to accept the revision and to submit it to the membership for vote. The complete revised document is printed on page 8. According to the present By-Laws the revision must be presented to the membership four months before a vote is taken. We urge all members to examine it carefully, as this is the document that will be voted on four months from now.

Dix Ward explains that the com-

mittee tried to maintain the intent of the founders that all professions dealing with hearing be welcomed to membership, and that no single individual or small group be allowed to seize power or become irrevocably entrenched.

Many issues were considered, he says, and as a result the revisions are numerous. Major changes include:

- (1) The change of name to the American Auditory Society;
- (2) The equivalent of a degree as a criterion for Membership, the equivalence to be decided by the Executive Committee;
- (3) A quorum of 20 for a Busi-

ness Meeting of the Society (we tried to be realistic);

- (4) Bylaw amendments to be effected only by letter ballot;

- (5) Provision for some pay for our hard-working Secretary-Treasurer;

- (6) Limitation that only one member of the Executive Committee can serve on the biennial Nominating Committee;

- (7) The provision that dues must be established by the Members at the regular annual meeting, not unilaterally by the Executive Committee;

- (8) Proxy votes to be abandoned;

- (9) To those who would like to (Cont. on Page 8)

What's Our CR?

(Convention Rating)

Members of scholarly societies are wont to gather clannishly in hotels for what is known as annual Conventions. At these conventions little scientific papers are read by the few and listened to by fewer, all the while the rest are jostling elbows in hallways, trying to remember names of old friends (sic), and hustling jobs or other interests. The *New Scientist* (Vol. 76, No. 1072) reveals that there is a hierarchy among scientific societies so far as hoteliers are concerned.

An American anthropologist approached a Chicago hotel this year hoping to arrange an Annual Convention for 2500 fellow anthropologists. He was initially turned down because of the small size of the meeting. But upon hearing that the organization was one of anthropologists the hotelier became quite eager to host the society. His change of heart was not due to the prestige of anthropology but to commercial factors related to the type of conventioners that

(Cont. on Page 10)

Annual Meeting Sparked by Davis

Hallowell Davis, distinguished scientist, noted neuro-physiologist, astute psycho-acoustician and great human being—received the Raymond Carhart Memorial Lectureship award at the Miami meeting of the AAS. He delighted an audience of some 60 members and guests with his articulate and informative description of the status of Electric Response Audiometry (ERA). At an evening "Dinner with Hallowell Davis" event he endeared himself to AAS members by reciting poetry and joining in informal fun.

No one can speak more appropriately on electric response audiometry than Dr. Davis. He first performed electric measurements on nerve impulses in 1926, and since 1934 has worked continuously with electroencephalograph studies. He has been at the leading edge of all of the developments in eeg application to auditory testing.

Dr. Davis reviewed the classification of Auditory Evoked Potentials (see Table I). He detailed each of these potentials but expanded particularly on the BSER-P6. This response, he states, is a robust and reliable endpoint for audiometry having the same low threshold at high frequencies and

poor synchronization at the low frequencies as the N1 of ECochG. The longer latency of P6 makes it immune to ordinary stimulus artifacts so that ordinary earphones are practical.

Davis stresses that the BSER-P6 has very high-reliability, and that sedation (not anesthesia) is sufficient for the child. BSER-P6 is therefore recommended for noncooperative children or adults. If specific frequencies are desired, a combination of the slow waking response or middle sleep response for low frequencies and BSER for 1000 Hz and higher is useful.

Following Dr. Davis' presentation three invited speakers discussed various aspects of middle ear pressure problems, ranging from high altitude effects to diving hazards. Lt. Col. Don Gasaway, Dr. Frederick Pullen and Dr. J. Brown Farrior addressed themselves to these unusual phenomena. Abstracts of their talks will be found in this issue.

Those who attended the evening "Dinner with Hallowell Davis" felt that it was an event which would become traditional. Future Carhart Memorial lecturers will hopefully meet with the membership informally as did Dr. Davis.

Symposium on the Pathology and Pathophysiology of the Eustachian Tube and Middle Ear

FREIBURG IM
BREISGAU, 9.28.-10.1.1977
reported by Imre Friedmann

The Symposium attracted a large number of participants to this picturesque town in the Black Forest, mainly from Germany itself, but with a generous sprinkling of guests from Sweden, England, Austria and Switzerland. Dr. Juhn from Minneapolis represented the USA. It was held in the splendid Lecture Hall of the University ENT Clinic created by the former Head, Prof. F. Zollner of Tympanosclerosis and Tympanoplasty fame. He opened the proceedings with a fine lecture on "The History of Eustachian Tube-research."

The present writer was perhaps the only person conscious of the fact that in Freiburg ASCHOFF had worked—the greatest pathologist since Virchow's period—whose textbooks on General and Special Pathology had guided and inspired many a budding pathologist before the last war.

The Symposium, devoted to the normal and pathological aspects of the middle ear cleft fitted ideally into the spirit of this great University. The lectures, followed by some lively and often heated discussions attracted a large and attentive audience, generously sustained by refreshments in the intervals.

On the first day the main topic centred around the Eustachian tube: its function and relation to the pathophysiology of the middle ear. The eminent speakers included Feldmann (Munster), Ingelstedt (Malmo), Palva

(Helsinki), Arnold (Dusseldorf), Munker (Freiburg), Aschan (Linköping), Tos (Hellerup), Plester (Tübingen), and others. The normal function and physiology of the E.T. formed the subject matter of the first session followed by papers on the malfunctioning tube. The influence of nasopharyngeal tumors, of the cleft palate and certain genetic factors were discussed in some detail.

The second day produced some lively arguments concerning the middle ear mucosa under "normal" and pathological conditions. There was an astonishing degree of similarity of the **Histological observations** as presented by Friedmann, Sade, Tos and Wullstein. Their interpretation, as known from the literature, generated some fierce controversy (enjoyed by all). Although the Symposium seemed to be in harmony on the important secretory role of the "transformed" middle ear mucosa in "secretory" otitis media, the terminology, however, has remained somewhat shaky...

I have considered the following points of relevance:

1. The normal mucosa is lined by flat cells forming a simple pavement epithelium. It has an inherent respiratory epithelial potential and qualities similar to those of the flat epithelium of the pulmonary alveoli. Therefore, it would react by a transformation into a cuboidal or ciliated columnar epithelium i.e.a. stratified or pseudostratified respiratory type epithelium with secretory elements such as goblet cells and gland-like structures included in it.

2. This transformation (or reversal) is not true metaplasia.

3. It is a reversal to its genetically determined respiratory type.

4. Metaplasia would refer only to the formation of true squamous epithelium in the middle ear cleft.

5. Simple stratification (often due to the oblique plane of sectioning of the temporal bone specimens) and loss of cilia do not justify the term "squamous", that should here be used only for keratinizing squamous epithelium whose cells produced keratin filaments and/or keratohyaline globules.

Sade has maintained that he has seen true squamous epithelium in the middle ear frequently (the illustrations shown were from nasal

or cervical polyps which of course in common with inflammatory aural polyps often display metaplastic squamous epithelium on their surface exposed to external irritants).

Sabina Wullstein presented a profusely illustrated paper (using three projectors and screens) of her extensive studies of the anatomy and topographic details of the tympanic cavity of considerable surgical and pathological importance. Dr. Tos, next to Sade the most prolific contributor, has drawn renewed attention to the importance of his widely acclaimed quantitative studies of the goblet cell population of the middle ear mucosa. It would require a great deal of patient and consistent work to repeat his important results.

Juhn from Dr. Paparella's department in Minnesota gave a good account of what is best in American otological research. The experimental approach using

(Cont. on Page 3)

Letter from England

The problems of the ear nose and throat have been attracting a good deal of attention not only among the specialists but also among what the Americans call generalists and general pathologists. The Journal of Pathology has published an interesting paper on the pathology of otosclerosis in which Dr. Ingle Wright, a former assistant of your reporter, has revived the vascular theory of the pathogenesis of this obscure condition causing deafness. An Editorial in *The Lancet*, anonymous but you may guess the author, has commented on this paper comparing it with the work of Lim and Saunders and with the opinion of the doyen of Otopathology John Lindsay who has often reflected on the obscurity of the cause of otospongiosis, to give it the more fashionable name.

It is interesting to note that the programme of the Winter meeting of the Pathological Society of Great Britain and Ireland has included several papers of ENT-interest and that at a recent meeting of the Otological Section of the Royal Society of Medicine there were five pathologists present: all specialists in the pathology of the ear nose and throat. The principal topic this time, not for the first time or for the last time either, was the pathogenesis of cholesteatoma. The metaplastic theory was ably defended by our old friend Jacob Sade and his splendid presentation has nearly converted the protagonists of the immigration theory. There must be even more close co-operation between surgeon and pathologist because the surgeon-pathologists, however excellent their pathology, cannot overcome their inherent clinical bias of interpretation.

have the wisdom and learning to advise presidents and legislatures.

They attempt to establish quotas, codes, and standards, including who is entitled to what—even who should be permitted to be born or to live. They decide that "zero growth," energy conservation and rationing, acceptable limits of unemployment and minimum wages, population density, racial make-up of schools and communities (as well as private businesses) are all within their purview.

Once such speculations were the realm of a few academics, isolated in their ivory towers, and accepted with bemused tolerance as "dreamers." Now, however, their voices are being heard more clearly, and their advice is sought more actively.

People no longer feel confident in their own views nor in the democratic processes. They look for faster, more "exact" solutions to problems, particularly those couched in the esoteric language of the "experts."

More frightening is the respect various branches of the elites pay to the opinions of their colleagues in other disciplines. Healthy skepticism, intellectual humility, a sense of awe and wonder, patient questioning and examination—once the marks of rational, scientific

(Cont. on Page 3)

You will be interested to know that parents of children with Down's Syndrome have been awarded a so-called "Mobility allowance" of 7 pounds or about 13 dollars weekly. This will enable them to keep their cars running and drive out into the country with the child.

Lastly, there is going to be a change at the helm of the old Journal of Laryngology. Sir Geoffrey Bateman is handing over the Editorship to John Ballantyne. We wish him every success in maintaining the high standard set by Sir Geoffrey during his tenure of this important post in the otolaryngological world.

—Imre Friedmann, London

Letter to the Editor

Dear Sirs:

First of all let me congratulate you and the American Audiology Society by the Corti's Organ (Audionews) which has been a newspaper very interesting and really keeps us up to date with the realizations in the field of Audiology, not only in your Country but as well as abroad.

I take the opportunity to inform you and the Society, that I've finished my MSc Course at Salford University (England) and I've received my MSc Diploma on the 14th July 1977, as you can see in the photocopies enclosed.

Finally I've been invited to take charge as the Clinical Director of the Speech and Hearing Clinic of the Parents Association to the Education of Deaf Children, which was supported by the Calouste Gulbenkian Foundation. The Clinic which was settled up in Lisbon has started working on the beginning of October.

Yours sincerely,
Paulo Noronha Pizarro.
Lisbon, Portugal

Hubert and the Space Problem

MEMORANDUM

From: Hubert L. Gerstman, D.Ed Chief
Through: Administrative Assistant
To: Hospital Counsel
Subject: Task Force Report on Space

The Speech, Hearing and Language Center, Staff Sub-Committee on Planning, formed a task force on space, April, 1975. Their report includes several options, one of which was designated as the most fruitful option to be given the highest priority.

Option 1 suggests the following plan:

1. In the absence of any further space contribution by the hospital, a plan is hereby submitted. The first stage of the plan is to double up offices for 2 of the speech clinicians. This would free up 1 office which could be then remodeled.

2. The remodeling would consist of measuring the height of the vacated room and installing a new horizontal partition locating it exactly half-way between the floor and the ceiling.

3. Two new doors to the room should then be constructed, 1 as an entrance to the upper portion of the room, and the second as an entrance to the lower portion.

4. Plates should be designed to identify the doors as being access to the upper level and the lower level respectively.

5. Furniture, somewhat reduced in size should then be duplicated for both the upper and lower levels.

This option has the affect of doubling the available clinical rooms for the Speech, Hearing and Language Center when carried out to its extreme of remodeling each room in the Center in a similar way. The phased approach to this, of course, is to do only 1 room at a time so that no clinical time is lost in the interim period.

The Task Force studied the ramifications of this approach and did note that 1 drawback to the plan would be that the case load would be restricted to children in the normal growth ranges under the ages of approximately 7 or 8 years of age. Another secondary drawback was noted by the Task Force in the area of personnel. The consequence of this particular renovation option would be that only midget speech pathologists and audiologists could be hired to fill the staff clinical positions.

The question to Hospital Counsel regards the interpretation of discriminatory hiring practices and whether or not height restrictions in job qualifications would be considered a discriminatory hiring practice. (See memos to Rehabilitation Commission, Architectural Services, Department of Physical and

Rehabilitation Medicine, Offices of Grants Administration Dental School/Medical School.)

H.L.G.

MEMORANDUM

To: Dean Dental TUSDM

From: Hubert L. Gerstman, D.Ed Chief
Subject: Affiliated Health Care Training

Pursuant to your request for new ideas relevant to the building of programs in the health care service area, the Speech, Hearing and Language Center has studied the field of speech pathology. It has come to our attention that a new job market may soon be created for speech pathologists who have undergone excellent training experiences, whose maximum height has been achieved at 4 ft. 1 in. (or who are not expected to grow beyond that height). It is projected that several positions will be available for persons meeting these qualifications over the next 3 to 5 years so that we would like to develop a curriculum that would meet these highly specialized needs.

Please feel free to contact us with any questions or comments or feedback you may have on this matter.

Thank you very much for your cooperation.

H.L.G.

cc Dean Medical
University President

MEMORANDUM

To: Grants Offices

From: Hubert L. Gerstman, D.Ed Chief
Subject: Possible funding sources

It has recently come to our attention that there may be a significant breakthrough in the design of hospital facilities for communication disorders centers. We were wondering how we might get together with someone from HEW (preferably NIH) to suggest the development of an RFP (request for proposal) dealing with the overcoming of architectural barriers in speech, hearing and language centers in the problem of very tall people. We feel that this area of investigation would be very heuristic and we would appreciate your help in designing an entire public appeal to solicit funds for the building of a programmatic concept in the relationship of height to communication disturbance.

We feel that the preparation of these materials should be written at the proper level.

Thank you for your cooperation in this matter.

H.L.G.

MEMORANDUM

To: Architectural Services

From: Hubert L. Gerstman, D.Ed Chief
Subject: Design of highly specialized chairs

It has come to our attention that the Speech, Hearing and Language Center, may be in need of a unique chair that seats 2 people. The chair would have to accommodate 1 person sitting so that his eyes would be at a height of 3 ft. 5 in., and another in the same article of furniture seated so that eyes would be at a height of approximately 8 ft. 2 in., measured from the floor to the head of the observer. These would be necessary for parents sitting outside a uniquely designed observation area. We will forward sketches of the concept once you have investigated the basic configuration described.

H.L.G.

MEMORANDUM

To: Rehabilitation Commission

From: Hubert L. Gerstman, D.Ed Chief
Subject: Short People

It has come to our attention that there may soon be a special program of advanced study developed in the communication disorders field that will be particularly designed for adults 4 ft. 1 in. and under. We were wondering if there are any special monies designated for the advanced academic and professional training of those handicapped by virtue of their height.

We were also wondering if there were any special programs for persons 4 ft. 11 2 in. or taller who wished their height to be reduced so they could meet particular vocational goals.

We would appreciate the forwarding of any information you might have on this subject area.

NOTE: If you are able to provide us with a positive response to our inquiries in paragraph 1, could you also be kind as to investigate the funds available for staffing grants for institutions providing employment to "very short people."

H.L.G.

MEMORANDUM

To: Department of Physical and Rehabilitation Medicine

From: Hubert L. Gerstman, D.Ed Chief

It has come to our attention that by 1980 we will be able to see our adult patients either on the floor of the Rehabilitation Institute or in wheelchairs that may be reclined so that the patient does not exceed a height of approximately 4 ft. 4

in, while seated in the chair. Current projections indicate that by 1980 this ceiling will be placed on our ability to serve clients. Perhaps the Research and Training Center might fund a project in conjunction with the Department of Bio-Medical Engineering for the design of chairs that would not exceed such specifications.

We are looking forward to your early reply.

H.L.G.

Big Green Publishing Company
762 Book Street
Omaha, Nebraska 681735

Dear Mr. Johnson:

We thank the members of your publications board and editorial staff for their acceptance of our fictionalized account entitled "The Cast of the Bureaucracy and the Little Green People." We fully accept and recognize the validity of your criticisms (paragraph 3, line 6) where you raise the question "...but what happens if someone actually tried to instigate such a scheme?" We have agreed to endeavor to insert a paragraph or 2 under Chapter 5 that would indicate that it would be impossible to manipulate the bureaucracy in such a manner.

We also agree that the exaggeration element is the major source for most of the humor in this story but it is difficult to respond to your editor's statement questioning whether or not the episode where the lawyer throws the plaintiff at

Symposium...

(Cont. from Page 2)

the chinchilla in their study of the pathology, biochemistry and immunology of otitis media will continue to provide valuable material as he has shown. The immunological reaction of the middle ear mucosa was further discussed by Kastenbauer and Hussl (a former co-worker of David Lim).

The organization of the Symposium was faultless and credit is due to Drs. Beck, Arnold and Munker. Dr. Arnold now with Vosteen in Dusseldorf is not only an excellent electron microscopist and surgeon but also a fine musician. With his friends he played in a Mozart quartet at an elegant reception at the ancient Kaufhaus—a most friendly occasion. So was the Dinner given by our three organizers and Dr. Beck revealed his particular talent as a poet reading his poem: "To Eustachius" with great success.

The ancillary arrangements and, in particular, the projection were superb: two or even three projectors used in the simultaneous projection of 2 or 3 slides. How am I going to get used to a single projector again?

the voice print expert is not a little too fantastic.

Our Department of Psychiatry tells us that frustration can build up over a period of years, that could conceivably lend credibility to such an episode.

We would prefer to leave the courtroom scene in its original form, although we are willing to modify the part of the bouncing and ricocheting around the judges bench. We also feel the same way about the hospital administration conference, although if you wish to reduce the time frame to 25 minutes instead of the original hour and 10 minutes, that would be satisfactory.

The editing of the violence that occurs in the ensuing scene may be a poor strategic move from the standpoint of marketability. We felt that the movie and television rights would be enhanced by the retention of that particular episode. We are all devoted to the climax when the conference table is destroyed by a single karate chop from the food service man who has stopped by to pick up the empty coffee pot.

Again, thank you for the check. You will be happy to know that we are using it to initiate certain drawings for an architectural modification of our clinic area.

Sincerely,
H.L.G.

tifically-inclined persons—are no longer acceptable. Quick, exact solutions, "correct answers," "objective" information—these are the currency of today's mandarins.

I have felt increasingly uneasy about these trends for years, but now I am positively terrified. Brave New World and 1984 pale into insignificance when compared with the implications of Vance Packard's "The People Shapers." Most frightening of all, it is now the "hard" sciences, not the soft, fuzzy "social sciences," which are preeminent in this new game.

Is it possible that mankind, in the name of reason, has abandoned reason for a new breed of tyrants?

Hearing Instrument Institute Plans Workshops

Three educational Workshops on Hearing Aids will be held in winter and spring of 1978, sponsored by the Hearing Instrument Institute (HII). They will be held in Las Vegas, Nevada, January 27-28, New Orleans, Louisiana, February 24-25, and in Atlanta, Georgia, April 2-3. The two day workshop will focus on the responsibilities and contributions of physicians, audiologists, and hearing aid specialists to the hearing impaired public. One otologist, one audiologist, one engineer, and two hearing aid specialists will comprise the faculty for each workshop. Opportunity will be provided for both formal and informal exchange of knowledge and expertise among the instructors and participants. Thirteen and one-half contact hours will be distributed over two days.

For further information contact: Mary Ann Armour, Executive Director, Hearing Instruments Institute, 301 Sovereign Court, Suite 108D, Manchester, Missouri 63011.

Arslan Wins Amplifon Award

Dr. Michele Arslan of the University of Padua was the recipient of the 1977 Amplifon International Prize. Dr. Arslan was honored for his long-term contributions to the knowledge of deafness. He has clarified particularly some of the aspects of Meniere's disease in his life-long work.

The award has been held previously by Dr. Jim Jerger of the U.S.

Cincinnati Hosts 1979 Symposium

The Department of Otolaryngology and Maxillofacial Surgery at the University of Cincinnati Medical Center and Children's Hospital Medical Center of Cincinnati announce a two and one-half day International Symposium on the Hearing Impaired Child. This Symposium, to take place in May 17, 18, 19, 1979 will bring together international workers in the field of the Child with severe hearing impairment.

The Symposium will concentrate on the Medical and Surgical evaluation and rehabilitation of these children in addition to the audiological aspects of detection, evaluation and rehabilitation.

The Symposium will be divided into Didactic lectures combined with workshops in which active

participation by the faculty and participants will be encouraged.

The Symposium promises to be a forum for the exchange of ideas amongst professionals in various aspects of management of the child with severe hearing impairment. For further details contact Dr. Allan B. Seid or Dr. Robert Keith at the University of Cincinnati Medical Center.

Dr. Allan B. Seid, Children's Hospital Medical Center, Elland & Bethesda Aves., Cincinnati, Ohio 45229, 513-559-4355.

Tracoustics Honors Outstanding Military Audiologist of 1977

Captain Steven W. Morris of Ft. Polk, Louisiana is the recipient of the 1977 Tracoustics, Inc. award to the outstanding member of the Military Audiology and Speech Pathology Society.

Captain Morris was selected as this year's outstanding MASPS member based upon his significant contributions to the Audiology and Hearing Conservation Programs at Ft. Polk, Louisiana, where he has been assigned as an Army Audiologist since his entrance to active duty in 1975.

The award was announced by Captain Donald R. Bender, current President of the Military Audiology and Speech Pathology Society, at the Annual MASPS Banquet at the Palmer House, in Chicago on November 2, 1977. Don M. Musick of Tracoustics, Inc. presented Captain Morris with a handsome bronze plaque to commemorate the award.

Abstracts of AAS Papers

DEVELOPMENT OF A MODIFIED SPEECH DISCRIMINATION TEST.

G. L. BULL
L. A. KIRWIN
R. A. RUTH
AND
Z. G. SCHOENY

* DEPARTMENT OF SPEECH
PATHOLOGY AND AUDIOLOGY
UNIVERSITY OF VIRGINIA
CHARLOTTESVILLE,
VIRGINIA 22903

Department of Otolaryngology and Maxillofacial Surgery, Charlottesville, Virginia 22901

Efficient acquisition of speech discrimination information rests upon an interaction among at least three factors: 1. the speed of administration, 2. the range of difficulty present in a given word list, and 3. the sensitivity, or ability of the list to effectively differentiate among various types of pathology. The purpose of the present study was to evaluate the feasibility of constructing a standardized discrimination test composed of highly discriminating items based on currently used speech materials.

Twenty adult listeners with normal hearing were presented with CID W-22 Lists 1 through 4. One fifth-word list was used to screen subjects and the remaining three lists were then presented in the presence of competing wide-band noise. A signal-to-noise ratio was employed that yielded a discrimination score of approximately fifty percent.

Results were consistent with previously reported findings that about 30 percent of the words in a list are unlikely to yield significant information about listeners, either because the words are seldom missed or often

missed. Of the remaining elements of the list two basic error response patterns were observed. One response pattern was comprised of words which tended to be consistently missed only by individuals with overall discrimination scores below a given range, while the other consisted of a group of words whose error response bore no systematic relationship to overall discrimination score.

Testing is presently underway to determine whether similar clustering effects are present in persons with hearing impairment. If so, it may be possible to construct lists of speech discrimination materials which differentiate patients more effectively without increasing the administration time required.

"COMPARISONS AMONG AUDITORY REACTION TIME, LOUDNESS AND CERTAIN CHARACTERISTICS OF THE ACOUSTIC REFLEX."

Lynne Marshall and John F. Brandt (University of Kansas, Bureau of Child Research, Lawrence, Kansas 66045)

Although the acoustic reflex threshold is often assumed to be loudness governed and the acoustic reflex threshold is often used as an objective measure of loudness recruitment, many experiments question whether loudness is the determiner of the reflex. Reflex threshold and equal loudness data often disagree. Loudness summation from wide- and narrow-band stimuli is often less than would be predicted from reflex threshold data. The size of the critical bands for loudness and reflex differ considerably. Loudness discomfort thresholds and the reflex threshold often disagree.

Certain response characteristics of the acoustic reflex have been described as a function of intensity, e.g., amplitude, latency, rise-time and fall-time as well as electromyographic data. The relation between these response characteristics and loudness have not been experimentally determined however.

Certain psychophysical procedures have traditionally been used to examine loudness, Magnitude estimation scaling techniques and auditory reaction time experiments are equally capable of producing equal loudness contours. Measures of the acoustic reflex as a function of time or intensity are traditionally gathered at a different time. The data are then compared and inferences about the relation of loudness and reflex activity are made assuming that the reflex activity is the same during the loudness measurement. In the present experiment the middle ear muscle activity was measured concurrently with auditory reaction time. Magnitude estimations of loudness for the same signals were also obtained.

Ten normal hearing listeners were instructed to respond as rapidly as possible (auditory reaction time) to tones ranging from 250 to 4000 Hz in octave intervals and broad band noise ranging from 35 to 115 dB SPL. Reaction time was measured on-line with an electronic counter. An FM tap recorder was used to record current middle-ear muscle activity from an electroacoustic impedance bridge for later playback and analysis on a digital storage oscilloscope.

Equal loudness contours generated from magnitude estimates

(Cont. on Page 5)

AAS . . .

(Cont. from Page 4)

mates were in good agreement with those obtained from previous researchers. Equal magnitude contours for reaction time were in good agreement with the equal-loudness contours. The usual relationships (inverse) between reaction time and SPL and loudness were apparent.

For equal sound pressures, low to mid frequency stimuli produced larger acoustic reflex contractions (amplitude), shorter reflex latency, and faster rise time than did high frequency stimuli. No relationship could be discerned between any of the reflex characteristics and loudness of the tone and noise bursts. None of the dynamic characteristics of the reflex showed evidence of being loudness governed at levels above the reflex threshold.

DIFFERENTIAL DIAGNOSIS OF COCHLEAR DISORDERS

Paul Yanick, Jr.
Stephen Freifeld

Cochlear hydrops is a disorder of the inner ear clinically manifested by the symptoms of fullness, tinnitus, and fluctuation in hearing loss. The basic theory of the origin of cochlear hydrops rests on the assumption that the endolymph within the cochlear duct is in some manner influenced either to increase its production or, because of a defect in the absorption, the volume expands. An increase in the osmotic pressure within the cochlear duct occurs, and a decrease in the efficiency of the hair cell processes results.

The sensation of fullness or pressure in the ear is the most constant and early complaint of this disorder. For this reason, careful attention should be focused toward distinguishing the fullness of cochlear hydrops from that of middle ear disorders. Impedance measurements are helpful in localizing fullness sensations from the middle ear. However, the role of impedance audiometry as a detector of pressure changes in the cochlea has not received adequate clinical exploration.

It has been demonstrated experimentally that increase and decrease in the fluid volume of the cochlea can be reflected as a change in impedance at the tympanic membrane. The purpose of this presentation is to relate the static impedance values in subjects with bilateral cochlear hydrops to audiometric findings and symptoms.

Gosselin and Yanick (1976) and Yanick (1977) reported audiologic and metabolic findings in 90 patients with fluctuating hearing loss. Fullness (86%) and tinnitus (90%) were the most common complaints. There were three basic groups of audiometric configurations: A mild low tone loss (50%), a moderate flat tone loss (31.3%), and a ski-slope or high tone loss (18.3%). Low frequency sensorineural hearing loss reflects the conductivity of the cochlea, and it seems reasonable to assume that impedance changes in the cochlea may be manifested at the tympanic membrane.

The Metz loudness recruitment test was positive in 71%, and bilat-

eral diplacusis was found in 68.7% of these patients. Interestingly, it occurred in 90% of the mild low tone loss group, in 72% of the flat loss group, and in only 6% of the ski-slope group. Speech discrimination scores were 82% at 30 dB sensation level and 68% at 45 dB sensation level. Raising the sensation level tends to stress the hydropic ear.

An abnormal glucose tolerance test was found in 58%, elevated triglycerides and cholesterol levels in 33%, and hypothyroidism in 13%. Treatment of the particular type of metabolic disorder resulted in relief of fullness and tinnitus in one-third of the 90 cases. Thirty cases were re-tested one month after dietary management and treatment had been administered. Fifty percent of these patients demonstrated improvements in discrimination scores and hearing thresholds. The other fifty percent reported relief from tinnitus and fullness.

Eighty subjects, or 160 ears with cochlear hydrops, were formed into three groups: Those with mild low-tone loss, moderate flat losses, and ski-slope losses. The range of bilateral static impedance values was 500 to 5000 ohms with a mean of 3333.3 ohms in the group with mild to moderate flat losses. The ski-slope group had considerably lower static impedance values with a mean of 1502.5 ohms consistent with normal reference data. Subjects in the latter group had normal hearing levels in the lower frequencies. In addition, the percentage of fullness and diplacusis was dramatically lower in this group as compared to those with either mild low tone or moderate flat losses. Thus the impedance pattern associated with cochlear hydrops seems to reflect the changes in fluid pressure in the cochlea that are a result of low tone losses.

The following case report may be illustrative: A 24-year-old law student had for several years complained of fluctuating hearing loss, fullness, recruitment, pitch distortion, and tinnitus. At the time of the original audiogram, he had no symptoms of fullness or pressure, no tinnitus, and a minimal hearing loss compared to previous audiograms. The static impedance values were 2000 ohms in both ears. One week later, he had a recrudescence of symptoms and hearing loss in the right ear. The test results showed increased hearing levels, and more importantly, increased static impedance values of 6000 ohms in the affected ear. The patient inhaled 95% oxygen and 5% carbon dioxide for 15 minutes, and after the inhalation, hearing levels had improved slightly (approximately 10 dB), but the static impedance had lowered from 6000 to 3000 ohms. The patient felt relieved from the pressure sensations and annoying tinnitus. Carbon dioxide inhalation has the effect of increasing blood flow to the inner ear, and it has been suggested that increasing the circulation may increase the potential capacity of the various sites in the inner ear which absorb endolymph.

In summary, a complete audiologic test battery that includes static impedance measurements can help to identify the finer details of cochlear pathology. Symptoms of fullness, tinnitus, pitch distortion, and hyperacusis

must receive their full share of investigative effort. Early detection and proper medical management are imperative as the chances of permanent loss is greater as the disorder progresses. Proper audiologic monitoring may permit the evaluation of the activity or abatement of pathology and provide assessment of the effects of treatment.

THE EFFECT OF PRESSURE ON PURE TONE THRESHOLDS

T. W. Norris, R. E. Jirsa, and
B. K. Skinner, University of
Nebraska Medical Center

In this study the authors examined auditory thresholds at different levels of positive and negative pressure. The purpose was to provide data on which to base a more reliable estimate of the degree of conductive loss from pressure readings. Reference was made to behavioral test findings in the child less than three years of age that suggest normal cochlear function while impedance measurements confirm negative middle ear pressure. Because there is no convenient method to determine actual organic thresholds, results are generally summarized by noting that "hearing function is probably within normal limits; however, in view of the negative middle ear pressure there is a possibility that a mild conductive type hearing loss exists." However, when considering the potentially harmful effects that a mild hearing loss can have on speech and language development in a child of this age, the question of degree

suggests the degree of conductive hearing loss that could be present at these same negative pressure values. The shift or conductive loss averaged over the speech range from 500, 1000, and 2000 Hz is approximately 8 dB for a -100 mm H2O pressure, 14 dB for -200 mm H2O pressure, 16 dB for -300 mm H2O pressure, and 20 dB for -400 mm H2O pressure.

In earlier investigations, there was surprising agreement between the threshold shift determined by Flisberg et al. who determined hearing shift with induced intertympanic pressure change in an otherwise normal ear and Sitler et al. who monitored hearing threshold at specific levels of organic negative middle ear pressure in children. Both studies indicated a shift of approximately 20 dB for the speech range average of 500, 1000, and 2000 Hz within a negative pressure range of 250 - 270 mm H2O. The threshold shifts observed in our study were slightly less than those observed in these referenced reports. For example, at 300 mm H2O pressure we found a shift of 16 dB for the speech frequency average. Our smaller threshold shift may be attributable to the fact that we used trained listeners and tested in a sound controlled environment, whereas, the Sitler et al. study involved children who were apparently tested as a part of a screening program, and the Flisberg study makes reference to thresholds recorded on only one subject.

In summary, the audiologist should suspect a conductive hearing loss that can reach levels of concern with negative middle ear pressure. The data confirm a loss

PURE TONE AUDIOGRAM

of conductive loss associated with changes in middle ear pressure becomes significant.

Ten normal hearing subjects were tested by presenting test signals through an ipsilateral probe which was sealed into the ear canal to accommodate specific intratympanic pressure changes of the ear being tested. The test signals were 250, 500, 1000, 2000, 4000, and 8000 Hz presented through intratympanic pressure levels of -400, -300, -200, -100, 0, 100, 200, 300 mm H2O.

To illustrate the clinical importance of negative pressure the audiogram demonstrates the threshold shift recorded at each negative pressure level. Assuming that the thresholds recorded at 0 mm H2O pressure represent audiometric 0 HL, the difference (shift) in dB between base line and thresholds recorded at -100 and -200 and -300 and -400 mm H2O pressure (to the nearest 5 dB)

of approximately 8 dB for the speech range of 500, 1000, and 2000 Hz with a -100 mm H2O pressure to approximately 20 dB for the same frequency average at -400 mm H2O pressure. Moreover, it is valuable to recognize that the greatest threshold shift occurs at approximately the mid-point of the speech range.

CONGENITAL MIXED DEAFNESS - PERILABYRINTHINE HYDROPS

J. Brown Farrior
Tampa, Florida
Clinical Professor Emeritus in
Otolaryngology
University of South Florida
College of Medicine

Round window membrane rupture, a cause of sudden deafness and a diving hazard, as just described by

Frederick W. Pullen, indicates the increasing incidence of spontaneous fistulas of the oval and round window as they are being diagnosed in otology today.

The purpose of this presentation is to state that these spontaneous fistulas of the oval and round window do not develop unless there is some congenital irregularity in the flow of cerebrospinal fluid into the inner ear and perilymphatic space. These congenital irregularities in the flow of cerebrospinal fluid may be either through an overly patent aqueduct of the cochlea or through the perineural spaces of the internal auditory canal. This excess flow of cerebral spinal fluid produces increased pressure in the inner ear which I have named "PERILYMPHATIC HYDROPS". The excess pressures in perilymphatic hydrops cause the spontaneous fistulas of the oval and round window.

Usually an excess flow of cerebrospinal fluid into the inner ear is sub-clinical, but in congenital mixed deafness these abnormal pathways in the flow of cerebrospinal fluid produce both a sensory neural hearing loss and a conductive hearing loss. The sensory neural hearing loss is a direct result of the perilymphatic hydrops from the excess pressures of the cerebrospinal fluid in the inner ear. These pressures produce the progressive destructive sensory neural hearing loss which usually occurs in the first month or years of life. The conductive portion of the congenital mixed deafness is produced by the same pressures of the perilymphatic hydrops which pushed the stapes outward so that it becomes locked and immobile in the overhanging anterior lips of the oval window niche, producing a condition which I have termed as a "LOCKED STAPES". If there are no overhanging anterior lips of the oval window, then these pressures simply push the stapes into the middle ear and there is a cerebral spinal fluid otorrhea and a total loss of hearing and these rare cases are simply diagnosed as a congenital nerve deafness.

I present these theories to the American Audiology Society with the hope that some of you can prove them to be fact and then we will be in a position to start surgical correction either by ablation of the aqueduct of the cochlea or by sealing the perineural spaces of the internal auditory canal and thereby stop this progressive destructive sensory neural hearing loss.

Unfortunately, most of the children with congenital mixed deafness are beyond the limits of audiologic diagnosis and the diagnosis must largely be based on history. First, there is the congenital mixed deafness and, although there is little speech discrimination, they can wear a hearing aid with considerably satisfaction and they have the typical soft voice of the conductive hearing loss with relative good speech and about the only test of any value is that they have good bone conduction for the lower tone frequencies, particularly when tested with the tuning forks on the teeth.

In an effort to substantiate the above theories, I will present a

New By-Laws . . .

(Cont. from Page 1)

eliminate all legalese from the Bylaws, it should be noted that Articles VII and IX of the proposed Bylaws were left essentially as is, because they have to do with our IRS status.

The members of the By-Laws Committee were: Laura Wilber, Jerry Tobias, Wayne Staab, Blair Simmons, Bert Scharf, Ross Roeser, Jerry Northern, Ralph

Naunton, Sam Lybarer, and Marion Downs. At the final meeting, invited guests President Geary McCandless and Editor Don Harris also contributed sound suggestions and helped break a deadlock or two.

Please read the new By-Laws carefully, and be prepared to vote when the mail ballot is sent out later this year.

ARTICLE I. NAME

1.1. The name of this organization shall be The American Auditory Society, formerly known as The American Audiology Society.

ARTICLE II. AIMS

2.1. The aims of the Society are to increase knowledge and understanding of the auditory process, promote conservation of hearing, and foster habilitation and rehabilitation of persons with hearing impairments. The Society shall coordinate the exchange and dissemination of information, particularly by holding regular meetings and publishing reports.

ARTICLE III. MEMBERSHIP

3.1. **Classes of Membership.** The Society shall be composed of Active Members and Life Members.

3.2. **Active Membership.** To become an Active Member of the Society, the applicant must (a) possess a Bachelor's degree from a recognized academic institution or (b) have had the equivalent of an academic degree in scientific experience or in professional experience in the field of audition, and must have demonstrated an interest in the field of hearing. Admission to the Society may be granted by the Executive Committee after the candidate has submitted an application.

3.3. **Life Membership.** An Active Member who has attained the age of 70 years, and who has been an Active Member of the Society for not less than 10 years, may become a Life Member by submitting a written request to the Secretary-Treasurer.

3.4. (a) **Dues.** Membership dues shall be established, upon the recommendation of the Executive Committee, by a majority vote of the Members present and voting at a regular business meeting of the Society. The annual dues may or may not include a yearly subscription to the official journal of the Society (known in 1977 as the Journal of the American Audiology Society).

(b) Dues shall be payable on the first day of each year and shall be considered delinquent if not paid by the last day of March of that year.

(c) Life Members shall be exempt from all dues except that portion covering subscription to the official journal of the Society. However, the Executive Committee may waive, on a year-to-year basis, such subscription costs, if the Society's financial condition permits.

3.5. (a) **Termination of Membership.** Members whose dues are delinquent shall be notified by the Secretary-Treasurer of such delinquency by the end of April of the year concerned. If the dues remain delinquent 30 days after such notification, membership shall be terminated. A Member whose membership has been so terminated may become a Member of the Society again only by applying for membership and being elected thereto in the manner herein prescribed. A penalty may be assessed for reinstatement.

(b) Any Member who is not delinquent in the payment of dues may file his resignation, in writing, with the Secretary-Treasurer, and shall cease to be a Member of the Society as of the date such resignation is filed. Dues paid are not refundable.

(c) The Executive Committee may expel from the Society a Member whose conduct it deems contrary to the best interests of the Society. Expulsion shall require concurrence by two-thirds (2/3) of the Executive Committee.

3.6. **Privileges.** Members and non-members may attend general meetings of the Society and may submit papers for presentation at meetings and/or for publication in a Society publication. Members shall receive publications, programs of Society meetings, membership lists and such other publications as may be authorized by the Executive Committee. Only Members shall be entitled to vote, to hold office in the Society, or to serve on its committees. Members may recommend subjects for study by the Executive Committee, may present resolutions or reports, may submit petitions for amendment or revision of the Bylaws, and may recommend locations for future meetings.

ARTICLE IV. MEETINGS

4.1. **Time and Location.** The Society shall ordinarily meet at least once a year and also at such other times and places, upon such notice as the Executive Committee may determine.

4.2. (a) **Business Meetings.** A business meeting shall be held during every ordinary meeting of the Society. Twenty Members present in person shall constitute a quorum at a business meeting. Policy decisions shall be made by a simple majority vote of those present and voting at a business meeting. In the event of a tie vote, the President shall cast the deciding ballot. However, the Executive Committee, when it deems necessary, may authorize a letter ballot to the entire membership for the purpose of establishing any decision.

(b) At each business meeting, Members shall be informed of all

actions taken by the Executive Committee since the last meeting of the Society.

4.3 **Rules of Order.** The meetings of the Society shall be governed by the rules contained in the then current edition of Roberts Rules of Order in all cases in which they are not inconsistent with the other provisions of the Bylaws of the Society.

4.4 **Minutes.** Minutes of all business meetings shall be recorded. They shall be signed by the President and the Secretary-Treasurer. They are to be subject to correction at the next following business meeting. The minutes are to be kept at the office of the Secretary-Treasurer, where they may be inspected by any Member. A summary of the proceedings of each business meeting shall be sent to all Members.

ARTICLE V. EXECUTIVE COMMITTEE

5.1. **Purpose.** The affairs of the Society shall be managed by an Executive Committee, as authorized by the Membership.

5.2. (a) **Composition.** The voting membership of the Executive Committee shall consist of fifteen Members of the Society.

(b) Fourteen members of the Committee shall be elected for a term of four years; seven shall be elected on odd-numbered years in a manner specified in the Statutes of the American Audiology Society. Each Member may be elected for two consecutive terms of office. Following a lapse of two years the Member may be reelected for two additional terms.

(c) For each election, the Executive Committee shall appoint a Nominating Committee representing insofar as possible the professions and interests of the entire Society. No more than one member of the Executive Committee can serve on the Nominating Committee. Before February 1 of odd-numbered years, the Nominating Committee will present no less than ten and no more than fourteen candidates to fill the seven available positions of the Executive Committee. These candidates should also be representative of the professions and interests of the entire Society. Candidates may also be nominated by a written petition signed by not less than ten Members and filed with the Secretary-Treasurer by June 1 of election years. Names and a brief biographical history of candidates shall be made available to the Membership prior to the election. Voting shall be performed by mail ballot in September of odd-numbered years and returned to the Secretary-Treasurer.

(d) In the event of the death or resignation of a member of the Executive Committee, the President shall appoint a replacement to complete the term of office concerned. This Member shall be eligible for election to two further consecutive terms of office.

(e) The fifteenth member of the Executive Committee shall be the Secretary-Treasurer, who shall be a Member appointed by the Executive Committee for a two-year term, to be renewed annually.

(f) Editors of Society publications shall be members ex officio of the Executive Committee, without vote.

(g) No remuneration for services shall be paid to any member of the Committee, except the Secretary-Treasurer. Remuneration for the office of Secretary-Treasurer shall be determined by the Executive Committee.

5.3. (a) **Officers.** The Executive Committee shall elect from among its members a President, a President-Elect, and an Assistant Secretary-Treasurer, all of whom, together with the Secretary-Treasurer, shall serve as the officers of the Society.

(b) The President of the Society shall be responsible for administration of the Society business and shall preside at all sessions of the Executive Committee and at Society business meetings.

(c) The President-Elect shall assist the President, shall perform the duties and responsibilities of the President in his absence, and shall assume the duties and responsibilities of the President if this office is vacated.

(d) The Assistant Secretary-Treasurer shall assist the Secretary-Treasurer, and shall perform the duties and responsibilities of the Secretary-Treasurer in his absence.

(e) The President and Assistant Secretary-Treasurer shall serve terms of one year each.

5.4. **Meetings.** The Executive Committee shall convene at least once during each Society meeting. It may also meet exceptionally on invitation by the President or at the request of six or more of the Executive Committee members. A quorum shall consist of eight voting members. Minutes of all meetings shall be recorded.

5.5. (a) **Decisions.** The decisions of the Executive Committee shall be determined by a majority of the members voting; should an equality of votes occur, the President shall cast the deciding vote.

(b) The Executive Committee shall determine its own internal rules.

5.6. (a) **Duties.** The Executive Committee shall act on behalf of the Society; it shall undertake all appropriate duties of management and of administration.

(b) The Executive Committee shall grant Membership to those applicants whose qualifications, in the Committee's judgment, meet the requirements specified in Article III, Section 3.2.

(c) The Executive Committee shall decide when and where the Society shall meet and shall elect a Program Chairman for that meeting. The Program Chairman shall be responsible for organizing the program and conducting the meeting. To this end, a Program Committee may be appointed by the Program Chairman.

(d) The Executive Committee, as directed by the Society Membership, shall have the authority to administer Society funds. Funds of the Society shall be managed by the Secretary-Treasurer.

(e) The Executive Committee shall report its activities and decisions to the Membership at least once a year.

ARTICLE VI. SECRETARY-TREASURER

6.1 (a.) **Duties.** The Secretary-Treasurer shall coordinate all correspondence and, in conformity with directives issued by the Executive

(Cont. on Page 10)

AAS. . .

(Cont. from Page 5)

series of stapes gushers of cerebrospinal fluid occurring during the course of stapedectomy. I will present cases of spontaneous cerebrospinal fluid otorrhea with either meningitis or diagnoses of Meniere's disease and I will show two cases on which I have performed an ablation of the aqueduct of the cochlea behind the round window in an effort to stop the excess flow of cerebrospinal fluid into the inner ear.

When, in the course of stapedectomy, the surgeon perforates the stapedial footplate and pulsating cerebrospinal fluid gradually fills the middle ear and the ear speculum and runs over the operating table and on the floor, that is known as "stapes gusher" and it can be controlled only by proceeding with a stapedectomy and fixing a viable graft in the oval window. This particular case was in an 8 year old boy with a congenitally mixed deafness.

My interest in congenitally cerebrospinal fluid otorrhea started with a 15 months old baby that had recurrent otitis media with three attacks of meningitis and whenever a myringotomy was performed there was copious flow of cerebrospinal fluid lasting about a week of ten days, or until the myringotomy had closed. Exploratory surgery revealed the stapes pulsating in the oval window and the copious flow (estimated between 500 and 1,000 ccs.) of cerebrospinal fluid which continued to fill the cavity. In the oval window there were no overhanging anterior lips to locate the stapes so that the stapes simply exploded into the middle ear and the flow of fluid could not be controlled with grafts in the oval window or by packing around the internal auditory canal. Opening of the horizontal semicircular canal revealed the markedly dilated vestibule typical of the true Mondini-Alexander. The flow of cerebrospinal fluid was finally controlled by packing the vestibule with a muscle graft so that the child has had no more meningitis, but of course she has total bilateral congenital nerve deafness.

In the stapes gusher of the cerebrospinal fluid, it is my opinion that it was an overlarge patent aqueduct of the cochlea while in this true Mondini-Alexander there would be patent perineural spaces at the internal auditory canal.

In the 8 year old boy with the stapes gusher, in 1965, I ablated the aqueduct of the cochlea by going anterior to the vertical facial nerve and behind the round window to transect the aqueduct of the cochlea, obtaining a copious flow of cerebrospinal fluid and then ablate the aqueduct of the cochlea. This ablation of the aqueduct of the cochlea gave him a 17 decibel hearing improvement in 1965 which gradually decreased until 1970.

These cases are shown in three dimensional photography in the Academy Atlases Tympanoplasty in 3-D, Volume II, Reels 23 and 24.

(Cont. on Page 9)

Minutes . . .

(Cont. from Page 1)

The meeting was called to order by President McCandless at 8:30 a.m.

1. The minutes of the 1976 Executive Committee meeting in Las Vegas, Nevada were presented to the members present and approved.

2. The following income and expense statement for the period January 1 through October 31 was presented and approved:

Income and Disbursement Statement for the period January 1, 1977-October 31, 1977	
Cash on Hand at 1 1 77	\$10,624.94
Membership Dues	7,892.34
JAAS Allowance	2,000.00
Sale of Mailing List	52.00
Sale of Advertising-C.O.	125.00
Total Assets	20,694.28
Equipment	190.63
Supplies	164.19
Postage-Office	379.87
Postage-Cortis Organ	456.00
Duplicating Costs	54.08
Telephone	176.63
Travel	78.40
Publication Costs-JAAS	10,920.00
Bookkeeping Costs-Cortis Organ	2,021.03
Bookkeeping Audit	170.00
Contract Service-Office	344.75
Contract Service-Cortis Organ	61.75
Convention Expense	264.73
JAAS Income Allowance Expense	2,000.00
Total Expenses	17,282.06
Cash on Hand at 10 31 77	\$3,412.22

A detailed audited financial report is published each year in the April issue of Cortis Organ.

3. A list of 114 persons who submitted applications during the 1977 calendar year was presented to the Executive Committee, with their highest held degree and the city and state of their residence. There being no objections to any of the persons applying, all were accepted as Members of the Society (The list appears at the end of the minutes).

It was suggested that in the future the list include the names of the two Members who sponsored the applicant and the list be sent to the Executive Committee Members one week prior to the annual meeting.

4. After discussion, it was decided that the 1978 annual meeting of the American Audiology Society will be held in San Francisco in conjunction with the annual meeting of the American Speech and Hearing Association.

The name of an AAS Member was suggested as Program Chairman for the 1978 AAS meeting. That person will be contacted by President McCandless and asked to serve as Program Chairman.

5. A motion was made and passed on the possibility of having the AAS sponsor a national meeting on a topic of broad interest. The rationale for having such a meeting is to increase the visibility of the AAS and ultimately enhance membership. Norma Hopkinson was appointed as the Chairman of a committee to explore having such a meeting. Bruce Graham and Dix Ward were appointed members of the committee.

6. J. Donald Harris reported on the status of The Journal of the American Audiology Society for the calendar year 1977.

a) Of 62 (sixty-two) manuscripts submitted, 35 were accepted, 24 are currently with reviewers or authors, and 3 were rejected outright.

b) Dr. Harris wished to express public appreciation to the following Section Editors:

Dr. Phillip Bellefleur	Dr. Thomas Porter
Dr. William Cooper	Dr. William Rintelmann
Prof. Marion Downs	Dr. Jay Sanders
Dr. George Gerken	Dr. Hiroshi Shimizu
Dr. A. Bruce Graham	Dr. John Sinclair
Dr. Norma T. Hopkinson	Dr. Richard Sweetman
Dr. George Lynn	Dr. W. Dixon Ward

c) JAAS was approached to publish the Proceedings of the National Symposium on Impedance Screening in Children in June, 1977 in Nashville, Tennessee. The proposal was not accepted, and Grune and Stratton will publish the proceedings in book form.

d) After discussion, the following motion was made:

"The Journal of the American Audiology Society be hospitable to receiving papers from The Society of Ear, Nose and Throat Advances in Children (SENTAC), provided that the manuscripts be reviewed by the officers of SENTAC and then reviewed by the normal JAAS process. Such manuscripts shall be identified in the journal as SENTAC transactions." (Passed)

7. Marion Downs reported on the status of Cortis Organ.

a) It was indicated that the format of the newsletter was appropriate as is.

b) It was decided to make one issue of Cortis Organ a membership promotional issue and send it to a different discipline each year depending on costs and the availability of funds.

8. Susanne Kos was appointed the Chairman of The Carhart Memorial Lectureship Committee. A summary of the recommendations of last year's committee will be obtained by Dix Ward from Tom Tillman. It was recommended that in future years a citation be written by the Chairman of the committee and sent to selected state, national, and international publications along with a photograph of the recipient.

9. Dix Ward presented and reviewed the newly proposed Bylaws the committee on Statutes revision had formulated. After minor changes the following motion was made:

AAS . . .

(Cont. from Page 8)

In a similar case with ablation of the aqueduct of the cochlea in 1969, the patient obtained a 13 decibel hearing improvement.

Certainly these results are equivocal.

This approach to the aqueduct of the cochlea is now used by Gacek in his section of the singular nerve for positional vertigo.

My interest in the aqueduct of the cochlea goes back to my work on the sublabrynthine approach to the petrous apex. The aqueduct of the cochlea could also be transected through a

transmastoid approach through the retrofacial cells and cut the aqueduct of the cochlea as it crosses the top of the jugular bulb. I believe that Glasscock has explored this possibility.

In regard to the spontaneous fistulas of the oval window, in 1965 I presented I believe the first such spontaneous fistula in which this 30 year old male with congenital deafness and cerebral palsy began in 1964 with spells diagnosed as Meniere's disease, but the spells were peculiar in that first he would have a click in the ear and then a spell of vertigo lasting for several days and, during this period, he would have a copious fluid post nasal discharge of cerebrospinal fluid. The stapedectomy revealed the

fluid coming out of the unlocked anterior lip of the oval window and the stapedectomy with sealing of the oval window with a large viable graft attached to the incus with stainless steel wire stopped all of his spells and he has had no further post nasal discharge or vertigo or tinnitus. His family and referring physician remain grateful over this 12 year period.

In another patient first presented with a 23 decibel hearing loss at age 10 and with audiograms at age 13, 17, 19 and 21 this progressed to a 62 decibel hearing loss.

Another patient with congenital mixed deafness, a very cooperative and intelligent male at age 26 could wear a hearing aid but only in his right ear with some satisfaction, for he had a total hearing loss in the left ear.

In 1972, the hearing in the right ear with the hearing aid suddenly became distorted and tinny and all sounds were just clattering noises so that he could not wear the hearing aid with satisfaction. The hearing recovered during April and May, but again in August there was marked distortion of hearing. I bravely explored this only hearing ear to find the stapes pulsating out of the anterior lip of the oval window and an anterior fistula of the oval window. This was sealed with a viable graft with no recurrence of the distortion of hearing and with continued satisfactory use of the hearing aid for the past five years.

In the course of several thousand stapes operations, I have had several patients with excess flow of cerebrospinal fluid out of the oval window and if the surgeon does not completely seal the oval window with a viable graft a blister will form under the mucous membrane of the middle ear, giving this patient a good pure tone hearing improvement but with marked distortion so that the hearing itself is unsatisfactory.

In vertigo in a true Mondini Alexander, Dr. William House has found a markedly dilated endolymphatic sac, indicating the destructive effects of the perilymphatic hydrops so that there is a through and through communication between the perilymphatic and endolymphatic system.

At the Academy in the fall of 1977, Clemis and Valvassori presented a paper "Congenital Hearing Loss associated with the Large Vestibular Aqueduct" substantiated by polytomographic findings. I expect this to be published in the Transactions of the American Academy of Ophthalmology and Otolaryngology.

These cases of excess cerebrospinal fluid pressure within the inner ear are presented to you with the hope of stimulating your interest in the possible diagnosis of "PERILYMPHATIC HYDROPS" and I hope that your future research will substantiate the following theories.

1. A spontaneous fistula of the oval or round window is dependent primarily upon an excess flow of cerebrospinal fluid into the inner ear through either an overly patent aqueduct of the cochlea or the perineural spaces of the internal auditory canal. The fistula itself may be precipitated by skin diving, exercise or any movement which increases the

"A copy of the proposed Bylaws be published in the January, 1978 edition of Cortis Organ. After a period of at least four months a mail ballot will be sent to all Members. Ratification will require two-thirds approval of those Members voting." (Passed)

10. Remuneration for the Secretary-Treasurer was set at \$50.00 per month, pending the acceptance of the newly revised Bylaws.

11. Hallowell Davis suggested that an AAS Member be appointed as liaison to the American EEG Association. Hiroshi Shimizu was appointed.

12. Sam Lybarger was elected from The Executive Committee members for the office of Vice President President Elect, 1978.

There being no other business, the meeting was adjourned at 12:05 PM.

Respectfully submitted,
Ross J. Roeser
Secretary-Treasurer

What's Our CR?

(Cont. from Page 1)

anthropologists are. For example, psychologists are known to consume great quantities of liquor at the bars, but tend to become argumentative and violent, generating large repair bills.

Mathematicians are the opposite: they seldom meet in bars for their arguments, preferring to stay quietly in their rooms to discuss earnestly their major divisions. Anthropologists are the happy medium—they drink liberally but while snogged do not wreck the place.

We are wondering whether a CR (Convention Rating) has been established for AAS among hoteliers. We like to think we rate with anthropologists as the perfectly balanced conventioners: convivial yet non-violent. Any ideas?

New By-Laws . . .

(Cont. from Page 8)

Committee, shall attend to the daily administrative and financial affairs of the Society, and shall take an active part in all committees dealing with publications. If, for some reason, the Secretary-Treasurer is prevented from carrying out his duties, he shall be replaced temporarily by the Assistant Secretary, or by a member of the Executive Committee designated by the President. Should the Secretary-Treasurer deem it necessary, personnel may be recruited to assist with Society work, subject to approval of the Executive Committee.

(b) The Secretary-Treasurer shall undertake the duties of Secretary to the Society Membership during the business meeting, and to the Executive Committee, as well as to any committees that may be set up by one or the other of these bodies. The Secretary-Treasurer or a person designated by him shall represent the Executive Committee on local organizing committees of Society meetings.

(c) The Secretary-Treasurer shall establish a bank account in the name of The American Auditory Society and shall conduct the necessary financial transactions of the Society. An audit of the financial status shall be performed annually by a certified public accountant and reported to the Membership.

ARTICLE VII. DEALINGS WITH THIRD PARTIES

7.1 Representation. The Executive Committee shall represent the Society in all its dealings with third parties.

7.2 Signatures. The Executive Committee shall designate those persons authorized to sign on behalf of the Society and shall decide on the title of signature.

7.3 Obligations. Members of the Society, as well as its agents and assignees, shall incur no personal financial obligation when acting on

the Society's behalf.

ARTICLE VIII. RULES

8.1 General. The Executive Committee may, by majority vote, interpret the meaning of these Bylaws and adopt Rules, not inconsistent with the Bylaws, to govern the activities of the Society.

ARTICLE IX. LIQUIDATION

9.1 Procedure. In the event of dissolution of the Society, for whatever reason and whenever this might be, this step will be undertaken by a Liquidator appointed by action of the Members at a business meeting, who shall also decide on his powers and, if applicable, fix his remuneration. In default of such an appointment, the liquidation shall be carried out by the Executive Committee in office at the time acting as Liquidators.

ARTICLE X

AMENDMENTS AND REVISIONS

10.1 (a) Procedure. Amendments or revisions of these Bylaws may be proposed either by the Executive Committee or by a petition signed by at least 40 Members.

(b) Notice of the general nature of any proposed amendments or revisions shall be given in a Society publication at least four months prior to a mail ballot.

(c) To become effective, such amendments or revisions must be approved by affirmative written ballot of two-thirds of the Members voting.

When QUIET is Important!

Precise audiometric measurements require quiet . . . the complete QUIET that comes with TRACOUSTICS Audiometric Examination Rooms and Suites.

TRACOUSTICS offers complete flexibility in planning your single or double wall Audiometric Examination Room or Suite with flush magnetic sealed

doors, carpeted floors, recessed lighting fixtures, and hidden electrical wiring.

TRACOUSTICS' qualified representatives will help plan your facilities and insure that they are promptly and properly installed. Call us collect for the name of our closest representative.

Book Review AAS . . .

The Acceptability of Risks, by Barry Rose, The Council for Science and Society, London, L5, 1977.

This report by a working group presents a factual discussion of the science of risk quantification. Its survey of industrial risk management would be of interest to AAS members, analyzing as it does the individual human response and the attitude of society to risk exposure. It recommends that those exposed to risks should have a powerful voice in deciding what risks they should be exposed to. How this can be done is not tackled straight-on; instead, the question is addressed "who should make the decisions?" An attempt is made to answer this question by setting up "risk advisors", or safety counsellors—but their role is not well-defined.

This report has been widely discussed in England and might be timely to consider in the U.S.

pressure of the cerebrospinal fluid.

2. Usually an excess flow of cerebrospinal fluid into the inner ear is sub-clinical.

3. In specific cases of congenital mixed deafness, these abnormal pathways in the flow of cerebrospinal fluid produce both a sensory-neural hearing loss and a conductive hearing loss. The sensory-neural hearing loss is a direct result of the excess pressures of the perilymphatic hydrops, these pressures producing progressive destructive pathology of the inner ear. The conductive portion of a congenital mixed deafness is produced by the same cerebrospinal fluid pressures, the perilymphatic hydrops, which pushes the stapes outward until it becomes locked and immobile in the overhanging anterior lips of the oval window niche, producing a condition which I have termed a "LOCKED STAPES".

4. If there are no overhanging anterior lips of the oval window, then the perilymphatic hydrops simply pushes the stapes into the middle ear and there is cerebrospinal fluid otorrhea and a total loss of hearing. In the past, these rare cases have simply died of meningitis or been diagnosed as a congenital nerve deafness.

5. The congenital irregularities in the flow of cerebrospinal fluid into the inner ear may vary from the sub-clinical overly patent aqueduct of the cochlea to the true Mondini Alexander as summarized by Illum and Everberg and Jensen.

6. In the true Mondini Alexander, the possibility of a locked stapes in the overhanging lips of the anterior niche of the oval window has not been noted in the pathologic reports.

Systematic Study Of Eustachian Tube Testing

Michael F. Seidemann and Melinda W. Seifert
Louisiana State University
Medical Center
New Orleans

Gregg D. Givens
Tulane University School of Medicine
New Orleans

The momentary measurement of middle ear pressure is likely to be a fleeting phenomenon (Feldman, 1976). The measurement of middle ear pressure may or may not be characteristic of "typical" middle ear pressure encountered in a specific middle ear (Beery and Bluestone, 1976). Therefore, additional information is needed to provide a definitive description regarding the ability of the middle ear-Eustachian tube complex to equilibrate ambient atmospheric pressure. It is no wonder that difficulty is experienced when we attempt to glean equilibration information from the mere determination of middle ear pressure. It is evident that a momentary measurement of middle ear pressure is of limited prognostic value. It therefore appears as if more emphasis should be placed upon the determination of pressure equilibration as an integral part of the middle ear measurement test battery.

Tests of Eustachian tube patency have previously been recognized as providing valuable data relative to the prediction of tympanoplastic surgical success (Holmquist, 1972). It is our contention that with a sufficient data base, the tympanometric determination of Eustachian tube patency can provide valuable predictive information, could reduce the numbers of over-referrals and at the same time initiate referrals that have been overlooked by false negative tympanometric pressure findings.

The subject population consisted of 26 adults between 20 and 30 years of age. A total of 48 ears met the inclusion criteria of tympanometry exhibiting normal middle ear pressure and function.

The procedure used was one adapted from the procedure outline by Williams (1975). The procedure was administered at +400, +350, +300, +250, +200 mm. H₂O.

The results of this study indicated a direct relationship between the pressure exerted and the amount of resultant pressure change obtained. It seems desirable to maximize the amount of pressure change obtained in Eustachian tube testing. The maximization of change obtained with normal ears should thereby enable the clinician to better visualize deviations from the norm in either direction.

The amount of pressure change obtained in this study was consistently greater with induced negative pressure than with induced positive pressure. The amount of pressure change obtained with maximum positive pressure (+400 mm) was less than the pressure change obtained with the minimum

negative pressure (-200 mm).

A direct relationship was found to exist between the amount of function change and the amount of pressure induced. It was recommended that an induced pressure of at least +350 mm be employed in the Eustachian tube test procedure in order to maximize the detection of function changes—5%. However, analyses of Eustachian tube test data should be biparametric (pressure and function) (Seidemann and Givens, 1977). With regard to the combined analysis of pressure and function data, it is felt that an induced pressure of -400 mm should be recommended for the test procedure.

Scientist Receives Award

The 1977 edition of the Centro Ricerche e Studi Amplifon International Prize—which is the most important award in the audiological field—has been attributed for the first time to an Italian scientist: Michele Arslan, who carried out his research work at the Ear Nose and Throat Clinic of Padua University. The motivation written by the 15 members of the Prize Committee emphasizes Arslan's "original and important contribution in the field of experimental physiology, physiopathology, clinical management and therapy of the inner ear diseases and in the field of the vestibular system."

Prof. Arslan dedicated his long scientific activity especially to Meniere's disease, obtaining excellent results by means of an original surgical technique, based on ultrasounds, which has been adopted all over the world and thus giving an essential contribution to the cure of this particular ear disease.

Prof. Arslan was presented with the Centro Ricerche e Studi Amplifon International Prize during a ceremony held at the Milan Press Club on November 24th, 1977.

Prof. Ettore Bocca, Head of the Ear Nose and Throat Clinic of the Milan University, introduced Professor Arslan, stressing his many scientific achievements, whilst Prof. Antonio Antonelli, Assistant Head of the Ear Nose and Throat Clinic of the Milan University, spoke on "Dizziness and the vestibular system: Prof. Michele Arslan's researches and discoveries."

In the afternoon of the same day, Prof. Arslan himself has acted as chairman of a round table on Meniere's disease, which took place at the Amplifon Research and Study Centre and to which Prof. Heinrich Spoendlin, Head of the Ear Nose and Throat Clinic of Innsbruck, and Prof. Jan Stahle, of the Ear Nose and Throat Clinic of Uppsala, participated.

Calendar of Events

January 19-20

Training Courses For Audiometric Technicians In Industry, approved for 15 contact hours by Florida Nurses Association. Further information from Larry B. Shipley, Jacksonville Hearing and Noise Control Inc., 836 Prudential Dr., Suite 531, Jacksonville, FL 32207, 904-399-1914.

January 22-26

Forty Sixth Annual Mid-Winter Clinical Convention, Otolaryngology, Los Angeles Hilton Hotel, Los Angeles, Ca. AMA and CMA 28 hour accredited course for Continuing Medical Education. Registration fees—\$175 for practicing otolaryngologists; \$75 for residents. Contact: Richard Pruter, Ex. Sec., P.O. Box 49412, Los Angeles, Ca 90049, 213-879-0143.

January 27-28

Electronystagmography And The Dizzy Patient, The Red Lion, Portland, OR. A two-day workshop on testing, interpreting and understanding the dizzy patient, conducted by Darrel L. Teter, Ph.D. and Frederick H. Linthicum, M.D. Fee—\$150. Contact: Tracoustics, Inc., Austin, Tx 78764, 512-444-1961.

January 27-29

Occupational Hearing Conservation Workshop and Refresher Course, Presbyterian Hospital, San Francisco. Contact: Continuing Education, Presbyterian Hospital, P.O. Box 7999, San Francisco, Ca. 94120.

January 30-February 2

Midwinter Research Meeting, Assn. For Research In Otolaryngology, Happy Dolphin Inn, St. Petersburg Beach, Fl. Contact: David J. Lim, President, Assn. for Research in Otolaryngology, 4331 University Hospitals Clinic, 456 Clinic Dr., Columbus, Oh 43210.

February 10-11

Electronystagmography And The Dizzy Patient, The Marriott, Atlanta, Ga. A two-day workshop on testing, interpreting and understanding the dizzy patient, conducted by Darrel L. Teter, Ph.D. and Frederick H. Linthicum, M.D. Fee—\$150. Contact: Tracoustics, Inc., Austin, Tx 78764, 512-444-1961.

February 24-25

The Hearing Aid Workshop For The Three Professions, Fairmont Hotel, New Orleans, La.

February 25-March 4

Second Midwinter Symposium On Frontiers Of Pediatric Otolaryngology, Snowmass, Co. Contact: George E. Shambaugh, Jr., M.D., American Hearing Research Foundation, 55 E. Washington St., Suite 2105, Chicago, Il 60602.

March 3-5

Second National Conference On Otitis Media, Scottsdale, Az. Co-sponsored by University of Arizona, College of Medicine with the Indian Health Service. Meets criteria of 18 credit hours in Category I of Physician's Recognition Award of AMA. Fee—\$200 before 1/9/78; late fee \$225. Contact: Office of Continuing Medical Education and Outreach, University of Arizona, College of Medicine, Tucson, Az 85724.

March 4-11

12th Annual Colorado Otolaryngology Workshop, The Mark at Lionshead, Vail, Co. Contact: Jerry L. Northern, Ph.D. or Marion P. Downs, M.A., Workshop Committee, P.O. Box B210, 4200 East Ninth Avenue, Denver, Co 80262.

March 8-11

Second International Symposium On Pediatric Otolaryngology, Kansas City, Mo. Contact: Basharat Jazbi, M.D., Professor and Chief, Section of Otorhinolaryngology, The Children's Mercy Hospital, 24th at Gillham Road, Kansas City, Mo 64108.

March 22-25

International Hearing Aid Seminar, Islandia Hyatt House, San Diego. Contact: Dr. Robert E. Sandlin, 8001 Frost Street, San Diego, Ca 92123.

March 27-31

Industrial Noise Measurement, Evaluation And Control (Course #202), National Safety Council Headquarters, 444 N. Michigan Ave., Chicago, Il. Contact: Director of Registrations, Safety Training Institute, 444 N. Michigan Ave., Chicago, Il 60611, 312-527-4800 ext. 283.

April 7-8

Electronystagmography And The Dizzy Patient, Hyatt Regency, Washington, D.C. A two-day workshop on testing, interpreting and understanding the dizzy patient, conducted by Darrel L. Teter, Ph.D. and Frederick H. Linthicum, M.D. Fee—\$150. Contact: Tracoustics, Inc., Austin, Tx 78764, 512-444-1961.

April 13-14

Basic Electronystagmography, Columbus, Oh. Fee—\$100. For further information: Charles W. Stockwell, Ph.D., 4024 University Hospitals Clinic, 456 Clinic Drive, Columbus, Oh 43210.

April 15-22

The Eng and Oto-Allergy Cruise Symposium, (Aboard ship in Caribbean). Co-sponsored by American Hearing Research Foundation and Northwestern University Medical School. Contact: George E. Shambaugh, Jr. M.D., American Hearing Research Foundation, 55 E. Washington St., Suite 2105, Chicago, Il 60602.

May 8-10

Designing For Noise Control, Seventh Int'l. Conference on Noise Control Engineering, Jack Tar Hotel, San Francisco, Ca. Contact: Conference Secretariat, INTER-NOISE 78, P.O. Box 3469, Arlington Branch, Poughkeepsie, NY 12603.

May 12-13

Electronystagmography And The Dizzy Patient, Wilshire Hyatt House, Los Angeles, Ca. A two-day workshop on testing, interpreting and understanding the dizzy patient, conducted by Darrel L. Teter, Ph.D. and Frederick H. Linthicum, M.D. Fee—\$150. Contact: Tracoustics, Inc., Austin, Tx 78764, 512-444-1961.

June 13-16

Acoustical Society Of America, Kingston, Rhode Island.

June 23-27

Biennial Convention Of The Alexander Graham Bell Association For The Deaf, St. Louis, Mo. Registration information available early spring. Write Convention Department, A.G. Bell Association, 3417 Volta Place NW, Washington, D.C. 20007, 202-337-5220.

September 1-3

Third Annual Conference Audiological Society Of Australia, Macquarie University, Sydney, Australia. Contact: The Public Relations Officer, Mr. Gary Walker, Audiology Development Section, National Acoustic Laboratory, 5 Hickson Road, Millers Point N.S.W. Australia 2000.

September 10-11

American Academy of Otolaryngology, Las Vegas, Nevada

September 15-17

Annual Meeting Of Society For Ear, Nose and Throat Advances In Children, Santa Barbara, Ca. For information write to: Dr. Sanford Gerber, University of California, Santa Barbara, Ca 93106.

October 2-6

Auditory Evoked Response Workshop and Symposium, San Diego, Calif.

November 12-16

XIV International Congress Of Audiology, Acapulco Cultural and Convention Center, Acapulco, Mexico. For information: Organizing Secretariat, Instituto Mexicano de la Audicion y el Lengua je, Progreso 141-A, Escandon Mexico 18, D.F.-Mexico.

November 18-21

American Speech and Hearing Association, San Francisco, Calif.

November 26-Dec. 1

Acoustical Society of America, Honolulu, Hawaii

1979 May 17-19

International Symposium Of The Hearing Impaired Child, University of Cincinnati Medical Center. Contact: Dr. Allan B. Seid, Children's Hospital Medical Center, Elland and Bethesda Ave., Cincinnati, Oh 45229.

amplaid 702

compliance and acoustic reflex meter ipsi- and contralateral reflex

- direct reading compliance meter in cc

- pressure range from — 500 mm H₂O to + 500 mm H₂O with automatic pressure limiter

- digital store of maximum compliance value for exacting acoustic reflex measurements

- entirely linear calibration of input/output function over the entire compliance range (0 to 5 cc)

- direct reading reflex meter in % variation of the maximum compliance value

- for contra- and ipsilateral reflex eliciting, pure tone stimuli (0.5, 1, 2, and 4 K Hz) and broad band noise as well as low- and high-pass filtered noise

- output to X-Y plotter and strip-chart recorder

amplaid

the line of specialised audiometric equipment

- miniprobe incorporating all transducers and large selection of tips to fit all ears

Volume 3, No. 2 April, 1978

Noise Symposium Presents

Comprehensive Offerings

Glorig To Be Honored

A symposium covering all aspects of noise will be held at San Antonio, Texas May 7-9. Sponsored by the National Foundation for Noise, Hearing and Balance, it will feature a large array of faculty members representing numerous disciplines and reflecting all the aspects of Noise and its Control.

Aram Glorig, AAS's founder and first president, will be the guest of honor at the Symposium. In addition, there will be repre-

sentatives from Otolaryngology, Audiology, Psycho-acoustics, Law, the U.S. Senate, Insurance, Environment Control, Marketing, Psychology, Physiology, the Armed Forces, Industry and Industrial Hygiene.

Concurrent with the symposium's lecture program will be an Industrial Audiometric Technician's course leading to Accreditation by the CAOHC. A hearing screening course for schools and clinical offices will also be offered to non-audiologists on May 10.

San Francisco To Be AAS Annual Meeting Site

John Sinclair and Terri Grekin, this year's program co-chairmen for the 1978 annual meeting of The American Audiology Society, are actively setting up schedules and making arrangements. Any sug-

gestions that members have are very welcomed. The meeting will be held on Friday, November 17th. Further details will be published in the July issue of *Corti's Organ*. Call for papers will be sent to each member in May.

CUNY

Sponsors

Hearing Aid Conference

The Ph.D. Program in Speech and Hearing Sciences of the City University of New York Graduate School is sponsoring a three-day conference on the "Acoustical Factors Affecting Hearing Aid Performance and Measurement" from June 14-16, 1978. The purpose of the conference is to present and discuss the implications of recent findings concerning the acoustical factors that influence hearing aid performance and measurement. The conference should be of interest and relevance to all persons involved in the design, manufacture, measurement and fitting of hearing aids.

The conference is designed to facilitate a dialogue among the various contributors and between the audience and the contributors. The practical application of research findings will be emphasized by the participation of experienced clinicians, engineers and scientists in "round table" discussions.

Participants will include researchers from the United States and abroad. A sampling of topic areas include:

Acoustics of the ear; influence of diffraction on hearing aid performance; room acoustics and intelligibility; earmold acoustics; hearing aid processed signals; hearing aid measurement standards; modeling the acoustic system; and hearing aid response characteristic selection strategies. For more information contact Gerald A. Studebaker or Irving Hochberg, Ph.D. Program in Speech and Hearing Sciences, Graduate School, CUNY, 33 W. 42 Street, N.Y., N.Y. 10036.

President's Message

F. Blair Simmons

Insofar as one can fix such things, this Society began as an outgrowth—not a tumor—of a meeting held in a Dallas hotel room years ago. Those of us who happened to be present (the meeting wasn't all that formal) earned our livings by about as many different ways as were possible to squeeze into one room (at least one each of the species known as deaf educators, otologists, hearing aid manufacturers, physiological psychologists (human and inhuman) and audiologists. The thing we had in common was an interest in people with hearing losses. Most of us or our counterparts found that while we were easily able to work together daily when dealing with an individual patient/client, it wasn't as easy when it came to our professional organizations. (Some of us also had strong feelings that we needed badly to recruit the interests of so-called basic scientists into becoming personally involved with the problems of deafened people). We had more than enough frustrations by the hierarchy of the status quo in the several separate professional organizations. Many times our organizations seemed to have dialogue only on, "who's in charge of what," or, "who owns what piece of the professional pie." We felt all us "professionals" got along pretty well on an individual basis, but in the separate societies one group tended to become the tactical "enemy" of the others. Thus in a sense the beginning of this Society was a protest movement.

Having decided that a mutual forum was an idea we could all be enthusiastic about, the next inevitable question became: who gets to belong to our club? Things got sticky right away. My vote was for anyone who had a documentable interest in hearing. I lost. The by-laws called for some sort of institutional degree. (I do admit that such a requirement is reasonable. One simply must establish a minimum standard to keep the natives peaceful—and the Society prestigious). Next we needed a name. We all thought the American Audiological Society seemed good. We have since learned that it isn't. ASHA said we couldn't use "audiology". That word belongs to them. (We heard no formal objections to "borrowing" the word, "american"). This picaresque problem of our Society's name was the first real challenge towards our goals, and we failed it. Professionalism, won once again.

My "president's message" is, let's not forget the enthusiasms of our beginnings, the reasons we felt this Society was needed. Part of this can be done by a continuing effort to recruit new members whose sympathies are similar, and to continue reminding old members that membership itself should be a clear statement in favor of less professionalism and more communication. And, we can communicate. We've got a first-class newsletter in *Corti's Organ* (which I suspect becomes Corti's orgasm near the publishing deadline), the beginnings of a fine journal, and an annual meeting. Use them.

CORTI'S ORGAN is a quarterly publication of the American Audiology Society, printed in Dallas, Texas.

Editorial

In a short while you will receive ballots for the New By-Laws that have been proposed for AAS. We hope you have read them carefully and are prepared to cast a well-considered vote. The By-Laws committee wanted particularly to have the new document reflect the chief goal of the Society: to provide a forum and meeting ground for all the various disciplines concerned with audition. In order to accomplish that goal the membership requirements have been made more lenient, and it has been made easier to effect policy changes. A great deal of flexibility will result, leaving the organization ready for whatever its destiny may be.

Of course, destiny is shaped by individuals, and we hope that the AAS officers and members will be inspired to request

innovative activities for the organization, such as the national meeting that was proposed at the Miami convention. Such an activity will give the Society the stature it should have.

So we conjure the membership to vote advisedly on the By-Laws, and to give support to Norma Hopkinson, Bruce Graham and Dix Ward in their planning for a national conference that will give AAS visibility. We may soon see AAS making a substantial, non-political, scientifically-based contribution to knowledge of the auditory function.

If you did not read the proposed By Laws in the January issue of Corti's Organ, we have reprinted them in this issue on pg. 12-MPD. RJR.

Letter

from England

The importance of immunology in otorhinolaryngology has been greatly enhanced; but there exists a great deal of confusion or difficulty in the interpretation of a vast amount of rapidly accumulating experimental and clinical findings.

A lecture at the Department of Immunology of the Clinical Research Center and Northwick Park Hospital in Harrow (England) on March 3d by Henry Claman, Professor of Immunology, University of Colorado Medical Center in Denver was most stimulating and illuminating in this respect. A pioneer in this field he has guided his audience with masterly clarity towards a better understanding of the

immunological mechanisms of tolerance without disguising the not negligible obstacles still to be surmounted. The lecture was acclaimed by a large and knowledgeable audience headed by Dr. Geoffrey Asherson himself an immunologist of world-wide repute.

I am glad to mention that the Journal of Laryngology will be under the joint Editorship of Sir Geoffrey Bateman and John Ballantyne a strong team supported by occasional anonymous advisers.

The crocuses are blooming in our garden and Spring cannot be far away. The itinerant symposiasts have started packing their slide-boxes.

Imre Friedmann

When QUIET is Important!

Precise audiometric measurements require quiet . . . the complete QUIET that comes with TRACOUSTICS Audiometric Examination Rooms and Suites.

TRACOUSTICS offers complete flexibility in planning your single or double wall Audiometric Examination Room or Suite with flush magnetic sealed

doors, carpeted floors, recessed lighting fixtures, and hidden electrical wiring.

TRACOUSTICS' qualified representatives will help plan your facilities and insure that they are promptly and properly installed. Call us collect for the name of our closest representative.

TRACOUSTICS

P.O. Box 3610 Austin, Texas 78764 (512) 444-1961

Sentac Meeting Announced

Sentac Meeting, Announced
The annual meeting of the Society of Ear, Nose and Throat Advances in Children (SENTAC) will be held at El Encanto, Santa Barbara, California on December 7 and 8, 1978. The deadline for abstracts for papers will be on June 15, 1978. Papers on 1.) Central Auditory Dysfunction 2.) The Effect of Moderate Hearing Loss on Language Development and Educational Achievement will receive preferential consideration. For further information, please write to Dr. Robin Cotton, Children's Hospital Medical Center, Elland & Bethesda Avenues, Cincinnati, Ohio 45229.

Report of Vanderbilt Impedance Symposium

USE OF ACOUSTIC IMPEDANCE MEASUREMENT IN SCREENING FOR MIDDLE EAR DISEASE IN CHILDREN**

This report is based on formal presentations and discussions at a Symposium on Impedance Screening for Children held at Vanderbilt University School of Medicine, Nashville, Tennessee, June 20-22, 1977. The Symposium began with invited "state-of-knowledge" reports on the following aspects of middle ear disease and impedance testing in children:

Epidemiology and Natural History of Middle Ear Disease—Jerome O. Klein, M.D. Morbidity of Middle Ear Disease—Charles D. Bluestone, M.D. Methods of Identification of Middle Ear Disease—Gunnar Liden, M.D.

The remainder of the Symposium addressed the issue of using impedance for screening four categories of children. Each category was introduced by a state-of-knowledge report on impedance screening of:

Infants—Robert H. Margolis, Ph.D. Preschool Children—Jack L. Paradise, M.D. School Age Children—Denzil N. Brooks, M.Sc. Special Populations of Children—Jerry L. Northern, Ph.D.

In addition, 20 papers were presented from among those submitted by investigators concerning recent studies of impedance screening in children. The Symposium had an open registration with more than 300 health professionals of varying disciplines in attendance. The format of the Symposium allowed for open discussion of both invited and selected papers. At the conclusion of the formal presentations a Task Force of 28 experts from the fields of audiology, otolaryngology, pediatrics and epidemiology met to formulate recommendations for the use of impedance screening for the detection of middle ear disease in children. In order to obtain the reactions of all persons attending the Symposium, the recommendations of the Task Force were presented and discussed at an open meeting. Although not all members of the Task Force agree with every point, the following is the consensus of the Task Force.

RECOMMENDATIONS FROM THE TASK FORCE

INTRODUCTION

Otitis media with effusion is prevalent among infants and young children. The disease is often associated with conductive hearing impairment, but the degree of this impairment varies. Moreover, the course of this type of middle ear disease is also highly variable and generally unpredictable. Some cases resolve spontaneously within short periods of time while others

continue for months or longer. In part for these reasons, controversy exists concerning the advisability of treating this type of middle ear disease if, as is often the case, it is unaccompanied by symptoms. There is some evidence that early treatment may be of advantage in preventing certain unfavorable long-term developmental consequences in some children, but the evidence for this is not conclusive and more studies are necessary to confirm this possibility.

Of particular concern are those infants and children in whom middle ear effusion is accompanied by hearing impairment that goes unnoticed for long periods. As the number of such infants and children is thought to be large, it appears desirable to develop screening methods for identifying them. In recent years measurements of the acoustic impedance of the ear, a technique for identifying middle ear effusion and certain related disorders, has attracted widespread interest among health professionals, educators, and legislators because of its potential as a screening method.

This report is based on available information and gaps in knowledge regarding the use of impedance measurements for screening children. It suggests interim conclusions and recommendations concerning the use of impedance for screening and implies areas for future research. Since new information on this subject is being acquired rapidly, the recommendations in this report probably will require early revision.

IMPEDANCE SCREENING FOR CHILDREN

Screening is a process by which individuals are identified who may have diseases or disorders that are otherwise undetected. Middle ear disease is a disease that may prove suitable for screening because 1) it is an important health problem; 2) it is prevalent; 3) there are accepted criteria for its diagnosis; and 4) facilities are available in many communities for its confirmatory diagnosis and its management (although in other communities such services are deficient). A fifth important criterion for suitability of the disease for screening has not been established: namely, that there is value in treating apparently non-symptomatic children or children with little or no hearing impairment.

Impedance screening comprises either tympanometry or measurement of the acoustic reflex or both, carried out by means of electroacoustic impedance instruments, and is intended to detect the presence of middle ear effusion or of certain other less common otologic disorders. These diseases have a high degree of association with conductive hearing loss, the most common type of hearing impairment in children.

The extent varies to which im-

pedance screening fulfills the principal criteria for an effective screening test—acceptability, reliability, validity, and reasonable cost. Impedance testing is acceptable to both the child and the provider of health care because it is safe, non-invasive, and simply executed. Studies

have shown impedance measurement to be reliable, but these studies have not involved subjects of all age groups or instruments of all types in current use. The validity of referral criteria based on impedance measurements (i.e., their association, singly or in combination, with the presence or absence of middle ear disease) has not been established completely, and further studies are needed. In these studies, tests results should be correlated with either (a) otologic findings by observers whose otoscopic diagnoses have themselves been validated, or (b) myringotomy findings. Minimum performance standards and design objectives of electroacoustic impedance devices are being studied by the American National Standards Institute, S-3 60. The costs of impedance screening are reasonable if overreferral rates are not excessive.

RECOMMENDATIONS

Because of the importance of middle ear disease in infants and children and in view of the need for additional information concerning its natural history and optimal management, the Task Force recommends that such information be sought as rapidly as possible through appropriate studies. At the present time, and until additional information has been developed, the Task Force does not recommend the use of impedance measurements for universal (mass) screening on a routine basis for the detection of middle ear disorders in children of any age group. Although not now recommending mass screening, the Task Force recognizes that in some locales screening programs have already been, or will be, established. Because these programs may afford opportunities to gain additional knowledge about the utility of im-

pedance screening, the Task Force recommends that wherever possible they be designed, or their designs be modified, to accomplish this purpose. Further, the Task Force strongly recommends additional research specifically designed to evaluate impedance testing as a screening method for infants and children.

Infants (0-24 months). Middle ear effusion has its highest incidence and prevalence in the age group 6 to 24 months. Following episodes of acute infection, asymptomatic middle ear effusions continue for extended periods in a large number of infants, and there is concern about the possible effects of undetected effusions on their function and development.

Below the age of seven months the relations between the tympanometric findings (using instrumentation thus far studied in this age group) and middle ear disorders are not well understood, although the limited data now available indicate that the sensitivity of tympanometry as usually performed is relatively low. Preliminary data, employing a probe tone of 660 Hz, suggest that in such infants acoustic reflex measurements may be of value in detecting middle ear effusion, and if so, might constitute an effective screening method. Additional studies on this population are required.

There are also feasibility problems associated with impedance screening of infants. Logistically it may be difficult to gather infants for testing after they leave their place of birth. Moreover, impedance testing in infants may sometimes be difficult and time consuming. Research is needed to develop screening methods for infants that have high degrees of sensitivity, specificity, and feasibility.

Preschool and School Age Children: Even though mass screening of preschool and school age children by impedance measurements is not recommended at present, such screening is already being performed, planned or contemplated in many communities. In situations where screening is or becomes a reality, the following

procedures and criteria have been judged to be minimal:

1. A combination of tympanometry and acoustic reflex measurement should be used.

2. For eliciting the acoustic reflex, a signal of 105 dB HTL should be used in the contralateral mode, or a signal of 105 dB SPL in the ipsilateral mode, or both.

3. Whether broad-band noise or pure tone is preferable as an eliciting stimulus for the acoustic reflex remains to be established. A pure tone between 1000 Hz and 3000 Hz would be acceptable for this purpose. The stimulus should be specified or described, or both.

4. Acoustic reflex measurements can be obtained either with the ear canal air pressure that results in minimum acoustic impedance or with ear canal air pressure equal to ambient pressure. The condition used should be specified.

5. For tympanometry, a 220 Hz probe tone is preferred. However, other low frequency probe tones, up to 300 Hz, are acceptable.

6. For tympanometry, an air pressure range of -400 to +100 mm(H₂O) is preferred. However, a range of -300 to +100 (H₂O) is acceptable. Automatic recording should be used whenever possible and the rate of air pressure change should be specified.

7. Failure on the initial screening test is denoted by either an absent acoustic reflex or an abnormal tympanogram. An abnormal tympanogram is defined as one that either, a) is flat or rounded (i.e., without a definite peak), or b) has a peak at, or more negative than, -200 mm (H₂O). Flat or rounded tympanograms appear to be more highly correlated with middle ear effusions than do tympanograms with peaks at negative pressure readings.

8. Any child failing the initial screening should be retested in four to six weeks. Parents or guardians should be advised accordingly. Any child who has an acoustic reflex and a normal tympanogram on the initial screening passes and is "cleared."

9. The following schema is recommended for various screening findings:

Cont. on page 10

CLASSIFICATION	INITIAL SCREEN	RETEST	SUBJECT OUTCOME
I	Acoustic reflex present and Tympanogram normal	Not required	Cleared
II	Acoustic reflex absent and/or Tympanogram abnormal	Acoustic reflex absent and/or Tympanogram abnormal	Referred
III	Acoustic reflex absent and/or Tympanogram abnormal	Acoustic reflex present and Tympanogram normal	At risk Recheck at later date

American Audiology Society Directory

The following persons were listed as current members of AAS as of March 1, 1978.

compliance and acoustic reflex meter
ipsi- and contralateral reflex

- direct reading compliance meter in cc
- pressure range from — 500 mm H₂O to + 500 mm H₂O with automatic pressure limiter
- digital store of maximum compliance value for exacting acoustic reflex measurements
- entirely linear calibration of input/output function over the entire compliance range (0 to 5 cc)
- direct reading reflex meter in % variation of the maximum compliance value

- for contra- and ipsilateral reflex eliciting, pure tone stimuli (0.5, 1, 2, and 4 K Hz) and broad band noise as well as low- and high-pass filtered noise
- output to X-Y plotter and strip-chart recorder

- miniprobe incorporating all transducers and large selection of tips to fit all ears

Classifications I and II should constitute the majority of children in a given population. Referral, when indicated after confirmatory retest, should be made to an appropriate health care provider in the community. Classification III constitutes a group of children that requires special monitoring by the agency responsible for the screening program. These "at risk" children should be retested periodically to determine the possible need for future medical referral. The Task Force emphasizes that more data are needed in order to further refine these screening criteria. Information concerning otologic findings and disposition in referred children is required in order to evaluate the utility of the screening process.

10. An optimal time and frequency for screening or referring particular populations cannot be advised at present because of lack of adequate information.

11. Headbands, if used, should be designed and manufactured to fit infants and small children. Probe tips should be soft and remain soft after use and cleaning. The entire probe assembly, including the tubing, should be durable.

12. Calibration of instruments should be performed routinely. This calibration should involve the intensity and frequency of the probe tone, the manometer for pressure variation, and the reflex-activating stimulus.

13. The agency responsible for a testing program must have facilities available for referral that include expert management. Prior to the initiation of a screening program, referral and management procedures must be defined.

14. Impedance testing should be supervised by professionals who are qualified by training and experience to perform and interpret impedance measurements. Because acoustic impedance testing may be performed by a variety of health specialists or paraprofessionals, there is a need for such individuals to receive specific training in the application of impedance measurements. A course, similar to that used for training industrial audiometric technicians, would offer some control of the competency of persons administering impedance measurements. A course, similar to that used for training industrial audiometric technicians, would offer some control of the competency of persons administering impedance screening tests. Need exists for a program similar to that of the Council for Accreditation in Occupational Hearing Conservation (COAHC). Since a nationally accepted program for training in impedance testing does not now exist, the Task Force recommends that such a course be designed by a group of professionals with recognized qualifications. This group should specify course content, format and length, qualifications of instructors, and other related

matters.

15. The cost of any screening program should be documented and should include the cost of confirmatory diagnostic tests.

16. Programs should be designed to gather information of value in defining the role of impedance measurement screening children for middle ear disease.

Special Populations. Because of high risk, serious consequences or known high prevalence, certain populations of children warrant special consideration for early detection of, and surveillance for, middle ear disease beginning soon after birth. These populations are:

Children with known sensorineural hearing loss*

Developmentally delayed and mentally impaired children*

Children with cleft palate and other cranio-facial anomalies

Native American children (Indian and Eskimo)

Children with Down Syndrome*

CONCLUSIONS

The Task Force strongly encourages continued investigation of this method for detecting middle ear disease in infants and children. The Task Force does not endorse universal (mass) impedance screening at this time. Finally, the Task Force emphasizes the need for research to further clarify the epidemiology, natural history and optimal clinical management of middle ear disease.

*Interpretation of acoustic reflex measurements should be made with caution in this group.

The Effect of Prolonged Noise Exposure on a Battery of Tests

Paper presented at the annual meeting of The American Audiology Society
December 12, 1977
Miami Beach, Florida
Gordon R. Bienvenue
Thomas A. Bennett
Adam Anthony
Paul L. Michael

INTRODUCTION

Recent research at the Environmental Acoustics Laboratory (EAL) has revealed the usefulness of a test battery including threshold, differential loudness sensitivity and masking tests for evaluating noise effects upon an (Bienvenue and Michael, 1977). When subjects were exposed to 95 dB SPL of noise for 15 minutes, 91% of them showed observable hearing changes using the testing battery. By contrast, only 64% to 67% of subjects showed hearing changes on individual tests in the battery.

It has been suggested that the testing battery advantage might be a temporary situation that would not be maintained for longer exposure durations. In considering this problem we turned to the observation (Mills et al, 1970; Carder and Miller, 1972) that prolonged exposure to a given sound gives rise ultimately to a maximum amount of threshold shift and that threshold shifts do not grow beyond this "asymptotic" value when noise exposure is continued. Therefore, with prolonged exposure duration, the varying effects of noise exposure upon different measures of hearing is reflective of differential amounts of noise induced hearing change and not of varying rates of growth of these effects. It was, therefore, determined to examine the effect of prolonged noise exposure upon our battery of hearing tests.

Asymptotic threshold shifts have been observed with exposure durations between eight and sixteen hours (Mills et al, 1970; Melnick, 1974; Melnick and Maves, 1974; Ward, 1975) and an exposure duration of 16 hours was selected for the present study.

Some temporary hearing effects of noise exposure may be due to the body's reaction to noise as a stressor. This stress response of the body alters the output of adrenal cortical hormones (principally cortisol) which in turn regulate other bodily functions. In order to assess the underlying physiological reaction to the noise exposure, blood samples were taken and analyzed for cortisol throughout the experiment. Subjects were 15 normal hearing young adults with a negative history of noise exposure and otologic disease. One ear of each subject was tested under earphones using the proposed test battery; then, (after a 1/2-hour break) the subject was exposed to the noise, and finally retested with the test battery in the period from 10 to 25 minutes after noise cessation. A follow up test was presented to each subject two days after noise exposure to insure that their hearing had returned to its pre-exposure state.

The masking test included in

the test battery was designed to measure the Level of Initial Masking (LIM) of a 4000 Hz test tone by several frequencies of masker tone. The Level of Initial Masking is defined as the logarithmic ratio of masker-to-test-tone that corresponds to the highest level of masker than can be tolerated by a listener while keeping a low-level tone barely audible. The subject was instructed to keep a 4000 Hz, 5 dB sensation level, pulsed tone barely audible by controlling the level of a continuous masker tone sweeping through the range from 100 Hz through 10,000 Hz. A Bekesy (1947) audiometer was used to produce the masker tone so that the subject could control the level of the masker while its frequency changed slowly. The sound pressure levels of the masker tones at the frequencies 250, 500, 1000, 1500, 2000, and 3000 Hz were determined and the sound pressure level of the test tone at 4000 Hz was then subtracted from these masker levels giving the noise-to-signal ratio we have called the Level of Initial Masking.

The differential sensitivity test was the Loudness Discrimination Test described by Michael and Bienvenue (1976; also Bienvenue et al, 1976 and 1977). The testing device randomly produced increments selected by the tester were 2.0, 1.5, 1.0, 0.8, 0.6, 0.4, and 0.2 dB. Each increment had an on duration of 200 msec with 50 msec rise and fall times. For loudness discrimination testing a tone of 4000 Hz was presented at 50 dB above normal reference threshold for that frequency (50 dB HL) and ten test items were presented at each increment magnitude. The subject was instructed to signal whenever he heard an increment in the 4000 Hz tone. The percentage of items correctly identified at each increment magnitude was recorded as the subject's score for that condition.

Blood samples were obtained from all subjects before, during and after the 16 hour noise exposure period. Cortisol levels were determined from the plasma fraction of each sample using a radioimmunoassay procedure.

RESULTS AND DISCUSSION:

Tests results were examined for magnitude of noise-induced shifts as well as for repeatability. Certainly, differentiation among those subjects who show a noise-induced hearing shift and those who simply vary due to test-retest error requires that testing error be significantly smaller than the shifts being examined. Repeatability of the data was evaluated using the two-day, post-exposure results for two listeners. The retest results were compared to pre-exposure data for each individual subject and the differences between initial and retest data were calculated.

The threshold data showed a 95% confidence interval of +6.8 dB (see Table I) and it was determined that a threshold shift must be greater than 7 dB in order to distinguish it from testing error.

The loudness discrimination

variability at each of the test increment magnitudes demonstrated 95% confidence intervals of +28% or smaller (see Table I) and it was determined, based on these results, that loudness discrimination shifts should exceed 30% in order to be distinguishable from testing error.

Finally the Level of Initial Masking data were examined and it was found that the 95% confidence interval for shifts in LIM was +3.2 dB or less (see Table I) and a criterion of 4 dB of shift at three of the six test frequencies was selected as the minimum shift which could be discriminated from test-retest error.

Keeping these criteria in mind, we will now consider noise-induced shifts in the test battery scores. The mean threshold shift at 4000 Hz following the 16 hour 85 dB (A) noise exposure was 10 dB. This shift was statistically significant at the .05 level.

Table II shows the mean loudness discrimination shifts observed at 4000 Hz. Noise-induced shifts were significant for loudness discrimination scores at the 0.2, 0.4, 0.6, and 0.8 dB increments.

TABLE I: TEST-RETEST DATA ON A BATTERY OF HEARING TESTS

Test Procedure	Thresh. (dB)	LD (%)	LIM (dB)
95% Confidence Interval	+6.8	+28	+2.7
Criterion*		7	30

*criterion is the value which must be exceeded for a shift to be measurable.

Thresh: Threshold

LD: Loudness discrimination score

LIM: Level of Initial Masking

TABLE II: NOISE-INDUCED SHIFTS IN LOUDNESS DISCRIMINATION AT 4000 HZ

Increments (dB)	Mean Shift (%)
0.1	7
0.2	29*
0.4	44*
0.6	28*
0.8	17*
1.0	3
1.5	0
2.0	0

LDI

54*

*shifts marked with an asterisk are significant with OL = .05

Although the proposed criterion was only exceeded at the 0.4 dB test increment, of particular interest is the row labelled Loudness Discrimination Index (LDI). This value is a record of the largest loudness discrimination shift for each listener regardless of the increment magnitude at which it occurred. Due to ceiling effects arising out of the baseline, loudness discrimination function, subjects vary greatly in the increment magnitude at which they show maximum shift. This tends

to obscure the loudness discrimination shift of statistical analysis. The Loudness Discrimination Index (LDI) characterizes the loudness discrimination shift independently of the baseline function (Bienvenue et al, 1977). Examination of Table II shows that the LDI for this group was 54% and was statistically significant.

Table III shows the mean Level of Initial Masking (LIM) shifts observed. The noise-induced shift in the Level of Initial Masking was significant at each frequency examined. Shifts in the Level of Initial Masking exceeded the proposed criteria at all masker frequencies except 2000 and 3000 Hz.

The data reported so far allow the conclusion that the three tests included in our test battery are sensitive to noise-induced, temporary hearing change. If we apply our previously developed criteria to the interpretation of individual test results in the 15 cases tested, we find that:

- 67% of the cases showed a measurable threshold shift,
- 73% of the cases showed a measurable Loudness Discrimination Index,

TABLE III: NOISE-INDUCED SHIFTS IN LEVEL OF INITIAL MASKING (LIM) AT 4000 HZ

Masker Frequency (Hz)	Mean Shift (dB)
250	-4.5*
500	-5.0*
1000	-5.6*
1500	-5.6*
1500	-4.1*
2000	-3.7*
3000	-3.0*
Average Across Frequencies	-4.4*

*shifts marked with an asterisk are significant with OL = .05

- 67% of the cases showed a measurable shift in the Level of Initial Masking, but

- 93% of the cases met the noise-induced shift criterion on at last one of the three tests in the battery.

While the signal tests are quite promising for the early detection of noise-induced hearing change in individuals, the combination of the three tests into a test battery is clearly a superior technique for this purpose EVEN WHEN EXPOSURE DURATIONS ARE PROLONGED. This conclusion is further supported by the correlations among the various component tests of the battery as shown in Table IV. Note that the LDI is poorly correlated to the TTS measure, indicating that these two measures do not duplicate one another. Thus, they can be expected to provide independent and useful information if they are both included in a test battery. The average LIM shift shows significant correlations to both the TTS and LDI measures indicating that LIM may be related to phenomena of both threshold and

loudness discrimination. The LIM may, then, provide supportive data for the other two procedures if included in the testing battery.

Finally, the average, percentage rate of change in the cortisol level was a 19% decrease. Correlation among individual shifts in cortisol level and in various parameters of hearing are reported in Table V. Note that significant correlations were obtained between cortisol level shift and LIM as well as between cortisol level shift and TTS.

TABLE IV: CORRELATIONS AMONG CHANGES IN THE COMPONENT TESTS OF THE HEARING TEST BATTERY

Tests being Compared	Correlation Coefficient
LDI with TTS	.10
LDI with LIM	.54*
LIM with TTS	.71*

*correlations marked with an asterisk are significant with OL = .05.

TABLE V: CORRELATIONS BETWEEN CORTISOL LEVEL CHANGES AND CHANGES IN PARAMETERS OF HEARING

Comparison of Cortisol Level shift with:	Correlation Coefficient
LDI	.05
LIM	-.67*
TTS	.82*

*correlations marked with an asterisk are significant with OL = .05.

In general, two conclusions may be derived from the results of this study:

- The superiority of the hearing test battery over individual hearing tests for the examination of noise-induced hearing impairment is observed for prolonged noise exposures as well as for brief duration exposures, and

- continued study of possible causal relationships between changes in serum cortisol levels and in parameters of hearing is warranted. A continuation of this research is currently underway with funding support from the Environmental Protection Agency.

Proposed By-Laws...

ARTICLE I. NAME

1.1. The name of this organization shall be The American Auditory Society, formerly known as The American Audiology Society.

ARTICLE II. AIMS

2.1. The aims of the Society are to increase knowledge and understanding of the auditory process, promote conservation of hearing, and foster habilitation and rehabilitation of persons with hearing impairments. The Society shall coordinate the exchange and dissemination of information, particularly by holding regular meetings and publishing reports.

ARTICLE III. MEMBERSHIP

3.1. **Classes of Membership.** The Society shall be composed of Active Members and Life Members.

3.2. **Active Membership.** To become an Active Member of the Society, the applicant must (a) possess a Bachelor's degree from a recognized academic institution or (b) have had the equivalent of an academic degree in scientific experience or in professional experience in the field of audition, and must have demonstrated an interest in the field of hearing. Admission to the Society may be granted by the Executive Committee after the candidate has submitted an application.

3.3. **Life Membership.** An Active Member who has attained the age of 70 years, and who has been an Active Member of the Society for not less than 10 years, may become a Life Member by submitting a written request to the Secretary-Treasurer.

3.4. (a) **Dues.** Membership dues shall be established, upon the recommendation of the Executive Committee, by a majority vote of the Members present and voting at a regular business meeting of the Society. The annual dues may or may not include a yearly subscription to the official journal of the Society (known in 1977 as the *Journal of the American Audiology Society*).

(b) Dues shall be payable on the first day of each year and shall be considered delinquent if not paid by the last day of March of that year.

(c) Life Members shall be exempt from all dues except that portion covering subscription to the official journal of the Society. However, the Executive Committee may waive, on a year-to-year basis, such subscription costs, if the Society's financial condition permits.

3.5. (a) **Termination of Membership.** Members whose dues are delinquent shall be notified by the Secretary-Treasurer of such delinquency by the end of April of the year concerned. If the dues remain delinquent 30 days after such notification, membership shall be terminated. A Member whose membership has been so terminated may become a Member of the Society again only by applying for membership and being elected thereto in the manner herein prescribed. A penalty may be assessed for reinstatement.

(b) Any Member who is not delinquent in the payment of dues may file his resignation, in writing, with the Secretary-Treasurer, and shall cease to be a Member of the Society as of the date such resignation is filed. Dues paid are not refundable.

(c) The Executive Committee may expel from the Society a Member whose conduct it deems contrary to the best interests of the Society. Expulsion shall require concurrence by two-thirds (2/3) of the Executive Committee.

3.6. **Privileges.** Members and non-members may attend general meetings of the Society and may submit papers for presentation at meetings and/or for publication in a Society publication. Members shall receive publications, programs of Society meetings, membership lists and such other publications as may be authorized by the Executive Committee. Only Members shall be entitled to vote, to hold office in the Society, or to serve on its committees. Members may recommend subjects for study by the Executive Committee, may present resolutions or reports, may submit petitions for amendment or revision of the Bylaws, and may recommend locations for future meetings.

ARTICLE IV. MEETINGS

4.1. **Time and Location.** The Society shall ordinarily meet at least once a year and also at such other times and places, upon such notice as the Executive Committee may determine.

4.2. (a) **Business Meetings.** A business meeting shall be held during every ordinary meeting of the Society. Twenty Members present in person shall constitute a quorum at a business meeting. Policy decisions shall be made by a simple majority vote of those present and voting at a business meeting. In the event of a tie vote, the President shall cast the deciding ballot. However, the Executive Committee, when it deems necessary, may authorize a letter ballot to the entire membership for the purpose of establishing any decision.

(b) At each business meeting, Members shall be informed of all actions taken by the Executive Committee since the last meeting of the Society.

4.3 **Rules of Order.** The meetings of the Society shall be governed by the rules contained in the then current edition of Roberts Rules of Order in all cases in which they are not inconsistent with the other provisions of the Bylaws of the Society.

4.4 **Minutes.** Minutes of all business meetings shall be recorded. They shall be signed by the President and the Secretary-Treasurer. They are to be subject to correction at the next following business meeting. The minutes are to be kept at the office of the Secretary-Treasurer, where they may be inspected by any Member. A summary of the proceedings of each business meeting shall be sent to all Members.

ARTICLE V. EXECUTIVE COMMITTEE

5.1. **Purpose.** The affairs of the Society shall be managed by an Executive Committee, as authorized by the Membership.

5.2. (a) **Composition.** The voting membership of the Executive Committee shall consist of fifteen Members of the Society.

(b) Fourteen members of the Committee shall be elected for a term of four years; seven shall be elected on odd-numbered years in a manner specified in the Statutes of the American Audiology Society. Each Member may be elected for two consecutive terms of office. Following a lapse of two years the Member may be reelected for two additional terms.

(c) For each election, the Executive Committee shall appoint a Nominating Committee representing insofar as possible the professions and interests of the entire Society. No more than one member of the Executive Committee can serve on the Nominating Committee. Before February 1 of odd-numbered years, the Nominating Committee will present not less than ten and no more than fourteen candidates to fill the seven available positions of the Executive Committee. These candidates should also be representative of the professions and interests of the entire Society. Candidates may also be nominated by a written petition signed by not less than ten Members and filed with the Secretary-Treasurer by June 1 of election years. Names and a brief biographical history of candidates shall be made available to the Membership prior to the election. Voting shall be performed by mail ballot in September of odd-numbered years and returned to the Secretary-Treasurer.

(d) In the event of the death or resignation of a member of the Executive Committee, the President shall appoint a replacement to complete the term of office concerned. This Member shall be eligible for election to two further consecutive terms of office.

(e) The fifteenth member of the Executive Committee shall be the Secretary-Treasurer, who shall be a Member appointed by the Executive Committee for a two-year term, to be renewed annually.

(f) Editors of Society publications shall be members ex officio of the Executive Committee, without vote.

(g) No remuneration for services shall be paid to any member of the Committee, except the Secretary-Treasurer. Renumeration for the office of Secretary-Treasurer shall be determined by the Executive Committee.

(5.3.) (a) **Officers.** The Executive Committee shall elect from among its members a President, a President-Elect, and an Assistant Secretary-Treasurer, all of whom, together with the Secretary-Treasurer, shall serve as the officers of the Society.

(b) The President of the Society shall be responsible for administration of the Society business and shall preside at all sessions of the Executive Committee and at Society business meetings.

(c) The President-Elect shall assist the President, shall perform the duties and responsibilities of the President in his absence, and shall assume the duties and responsibilities of the President if this office is vacated.

(d) The Assistant Secretary-Treasurer shall assist the Secretary-Treasurer, and shall perform the duties and responsibilities of the Secretary-Treasurer in his absence.

(e) The President and Assistant Secretary-Treasurer shall serve terms of one year each.

5.4. **Meetings.** The Executive Committee shall convene at least once during each Society meeting. It may also meet exceptionally on invitation by the President or at the request of six or more of the Executive Committee members. A quorum shall consist of eight voting members. Minutes of all meetings shall be recorded.

5.5. (a) **Decisions.** The decisions of the Executive Committee shall be determined by a majority of the members voting; should an equality of votes occur, the President shall cast the deciding vote.

(b) The Executive Committee shall determine its own internal rules.

5.6. (a) **Duties.** The Executive Committee shall act on behalf of the Society; it shall undertake all appropriate duties of management and of administration.

(b) The Executive Committee shall grant Membership to those applicants whose qualifications, in the Committee's judgment, meet the requirements specified in Article III, Section 3.2.

(c) The Executive Committee shall decide when and where the Society shall meet and shall elect a Program Chairman for that meeting. The Program Chairman shall be responsible for organizing the program and conducting the meeting. To this end, a Program Committee may be appointed by the Program Chairman.

(d) The Executive Committee, as directed by the Society Membership, shall have the authority to administer Society funds. Funds of the Society shall be managed by the Secretary-Treasurer.

(e) The Executive Committee shall report its activities and decisions to the Membership at least once a year.

ARTICLE VI. SECRETARY-TREASURER

6.1. (a.) **Duties.** The Secretary-Treasurer shall coordinate all correspondence and, in conformity with directives issued by the Executive Committee, shall attend to the daily administrative and financial affairs of the Society, and shall take an active part in all committees dealing with publications. If, for some reason, the Secretary-Treasurer is prevented from carrying out his duties, he shall be replaced temporarily by the Assistant Secretary, or by a member of the Executive Committee designated by the President. Should the Secretary-Treasurer deem it necessary, personnel may be recruited to assist with Society work, subject to approval of the Executive Committee.

(b) The Secretary-Treasurer shall undertake the duties of Secretary to the Society Membership during the business meeting, and to the Executive Committee, as well as to any committees that may be set up by one or the other of these bodies. The Secretary-Treasurer or a person designated by him shall represent the Executive Committee on local organizing committees of Society meetings.

(c) The Secretary-Treasurer shall establish a bank account in the name of The American Auditory Society and shall conduct the necessary financial transactions of the Society. An audit of the financial status shall be performed annually by a certified public accountant and reported to the Membership.

ARTICLE VII. DEALINGS WITH THIRD PARTIES

7.1 **Representation.** The Executive Committee shall represent the Society in all its dealings with third parties.

7.2 **Signatures.** The Executive Committee shall designate those persons authorized to sign on behalf of the Society and shall decide on the title of signature.

7.3 **Obligations.** Members of the Society, as well as its agents and assignees, shall incur no personal financial obligation when acting on the Society's behalf.

ARTICLE VIII. RULES

8.1 **General.** The Executive Committee may, by majority vote, interpret the meaning of these Bylaws and adopt Rules, not inconsistent with the Bylaws, to govern the activities of the Society.

ARTICLE IX. LIQUIDATION

9.1 **Procedure.** In the event of dissolution of the Society, for whatever reason and whenever this might be, this step will be undertaken by a Liquidator appointed by action of the Members at a business meeting, who shall also decide on his powers and, if applicable, fix his remuneration. In default of such an appointment, the liquidation shall be carried out by the Executive Committee in office at the time acting as Liquidators.

ARTICLE X. AMENDMENTS AND REVISIONS

10.1 (a) **Procedure.** Amendments or revisions of these Bylaws may be proposed either by the Executive Committee or by a petition signed by at least 40 Members.

(b) Notice of the general nature of any proposed amendments or revisions shall be given in a Society publication at least four months prior to a mail ballot.

(c) To become effective, such amendments or revisions must be approved by affirmative written ballot of two-thirds of the Members voting.

NEWS ON NOISE MEETINGS

26th Annual Institute in Occupational Hearing Loss

The University of Maine at Orono (Bangor) announces that the 26th Annual Institute in Occupational Hearing, directed by Joseph Sataloff and David Lipscomb, will be held July 17 to July 21, 1978.

The facilities of the University of Maine provide excellent accommodations for the participants.

The Institute is designed for industrial physicians, safety engineers, otolaryngologists, audiologists, health management executives and administrative personnel. Covers total field of conservation of hearing programs, medicolegal and compensation aspects, and OSHA developments. Awards 27 credits in PRA Category 1 of AMA for physicians. Tuition is \$275.00 and Room and Board is \$25.00 per day.

For descriptive brochure and application write or phone: UMO Coordinator, 1721 Pine St., Philadelphia, Pa. 19103 (215) 735-0205.

Noise Control Engineering begins 6th Year of Publication

NOISE CONTROL ENGINEERING, the only referred technical publication in the United States devoted exclusively to noise control, begins its sixth year of publication in 1978. NCE is published bimonthly in cooperation with the Acoustical Society of America. In-depth articles appearing in NCE cover topics such as techniques for machinery noise control, community noise, aircraft noise, standards and measurements and engineering

criteria for noise control. NCE was first published in 1973, and in October of that year Malcolm J. Crocker, Professor of Mechanical Engineering at Purdue University, was named Editor. Since that time Dr. Crocker has made NCE a leading technical journal with a world-wide circulation.

NOISE CONTROL ENGINEERING is published by the Institute of Noise Control Engineering (INCE), a non-profit organization for professionals in the

field. One of the purposes of the Institute is to advance the technology of noise control with emphasis on engineering solutions to environmental noise problems. The publication is available to libraries and to individual subscribers who may become Associates of the Institute.

Further information on NCE and other INCE publications may be obtained from the Institute of Noise Control Engineering, P.O. Box 3206, Arlington Branch, Poughkeepsie, NY 12603.

1st Annual Noise Measurement And Control Course

The University of Maine at Orono (Bangor) announces the 1st Annual Course in Noise Measurement and Control, directed by James L. Parsons, will be held July 17 to July 21, 1978.

The facilities of the University of Maine provide excellent accommodations for the participants.

Oriented to engineers, industrial hygienists, safety personnel and Federal and State inspectors, the course is presented to acquaint the participants with the methods for evaluating noise problems and working out solutions. The subjects of acoustics measurement, instrumentation, noise control, regulations, compliance programs, hearing damage and hearing conservation programs are treated and discussed thoroughly.

Laboratories provide practice in the use of sound measuring systems. Ample opportunity is

provided students to discuss individual problems with faculty members. Panel discussions with regulatory authorities and experts will be a special feature of the program. An excellent and renowned staff has been assembled to conduct this course. Tuition is \$300.00 and Room and Board is \$25.00 per day.

For descriptive brochure and application write or phone: NMC Coordinator, 1721 Pine St., Philadelphia, Pa. 19103 (215) 735-0205.

Inter-Noise Seminar

An intensive short course on principles and applications of noise control will be presented on 4, 5, and 6 May 1978 at the Jack Tar Hotel in San Francisco, California, immediately preceding INTER-NOISE 78. Seventh International Conference on Noise Control Engineering. The presentations on the first day will cover fundamentals of acoustics and noise control and will be given by Malcolm J. Crocker, Editor-in-Chief, NOISE CONTROL ENGINEERING and Professor, Purdue University and by William W. Lang, Program Manager, Acoustics Technology,

IBM. The presentations on the next two days will be given by noise control specialists from industry, government and universities and will cover: in-plant noise control, design of facilities for noise control, noise measurements and data reduction, and acoustical standards used in noise measurements. The registration fee for the Seminar is \$325.

Further details may be obtained from the INTER-NOISE 78 Conference Secretariat, P.O. Box 3469, Arlington Branch, Poughkeepsie, NY 12603 or telephone 914 462-6719.

Inter-Noise 78 to Discuss Progress in Noise Control

Two special sessions on European progress in noise control will be featured at INTER-NOISE 78, the seventh International Conference on Noise Control Engineering to be held at the Jack Tar Hotel, San Francisco, California, U.S.A. next May 8-10. During the Fall of 1977, Swedish industry initiated a campaign to reduce significantly the noise levels in working environments. A detailed description of this campaign will be given in a special session to focus on:

- Sweden's new approach to noise control in industry

The Swedish Foundation for Improving Worker Environments provided the funds to support this intensive campaign. A specially-prepared handbook on noise control principles and applications was circulated widely throughout Swedish industry. A number of industries were targeted for special consideration by task teams consisting of noise control engineers and industrial specialists. The INTER-NOISE 78 special session

will focus on the objectives of the new Swedish program and reports will be given on noise control in the targeted industries, including the stone processing industry, the mechanical industry, the food industry, the concrete prefabrication industry, the graphic arts industry, the textile industry and the pulp and paper industry.

Another special session at INTER-NOISE 78 will focus on:

- European noise regulations

The Environmental Action Program (covering the period 1977-81) of the European Community (Common Market) calls for the development of an anti-noise plan to control noise at its source and to take account of the environment in which the source operates. Papers to be presented at INTER-NOISE 78 from Austria, Denmark, France, Germany and the Netherlands will focus on activities within these countries to control noise, primarily at its source. Particular emphasis will be placed on the use of sound power levels to classify and regulate the

noise emitted by industrial noise sources as well as by household appliances. In the last decade, considerable progress has been made in Europe on classifying noise emissions in terms of the sound power levels of the sources and in controlling the emissions at the source. The European specialists who will be describing their programs will present to the INTER-NOISE 78 audience the latest advances from Europe in regulating and controlling noise at its source.

These two special sessions amplify the theme of INTER-NOISE 78 which is "Designing for Noise Control." Three other special sessions will also be given on the theme and five Distinguished Lecturers will present reviews of key topics in noise control engineering. A three-day Seminar will precede INTER-NOISE 78 to introduce newcomers to the fundamentals of the technology. Information on INTER-NOISE 78 and the Seminar which precedes it may be obtained from the Conference Secretariat at the address and telephone number above.

Third International Conference on Biological Effects of Noise

The International Commission on Biological Effects of Noise is pleased to announce the Third International Congress on Noise as a Public Health Problem: Biological and Behavioral Effects. The Congress is scheduled to be held during the week of September 25-29, 1978, in Freiburg, Federal Republic of Germany (West Germany). The official language of the Congress is English; simultaneous German translations will be provided. In addition to the invited and contributed papers on scientific research and applications, major discussions are planned on governmental and industrial needs and problems. Other discussions will be held on ways to develop procedures that will permit practical solutions both for

governments and for industries. Inquiries should be addressed to:

International Commission on Biological Effects of Noise; Institut für Arbeits- und Sozialmedizin; Universitätsklinikum; Johannes Gutenberg Universität; Obere Zahlbacher Strasse 67; D-6500 Mainz; Federal Republic of Germany.

The major topics that will be treated during the Congress are Community Response to Noise, Effects of Interactions between Noise and Physical or Chemical Agents, Influence of Noise on Performance and Behavior, Noise and Animals, Noise and Communication, Noise-Disturbed Sleep, Noise-Induced Hearing Loss, and Non-auditory Physiological Effects Induced by Noise.

International Audiology Congress Meets In November

XIV INTERNATIONAL CONGRESS OF AUDIOLOGY

CULTURAL AND CONVENTION CENTER

ACAPULCO - MEXICO November 12-16, 1978

Under the auspices of the International Society of Audiology.
Organized by the Instituto Mexicano de la Audición y el Lenguaje.

Organizing Secretariat:
Instituto Mexicano de la Audición y el Lenguaje
Ave. Progreso 141-A
Mexico 18, D.F. - MEXICO
Phone: 2776-444

For European countries:
Organizzazione Internazionale Congressi (OIC)
Via dei Bardi, 52
50125, Florence ITALY
Phone: (055) 212-590

President: Pedro Berruecos Jr., M.D.
General Secretary: Luis M. Valdés O., M.D.

GENERAL INFORMATION

The XIV International Congress of Audiology will be held at the Cultural and Convention Center in Acapulco, Mexico. The Convention Center covers a 14 hectares area and has everything to realize any type of convention or exhibition: travel agencies, post and telegraph offices, telex, long distance telephones, closed circuit television, restaurants, cafeterias, press halls, theaters, auditories and more of twenty assembly rooms. It is located in the best zone of the Acapulco bay and surrounded by gardens and hotels. In Acapulco, there are facilities for practicing all kinds of sports. The international airport and the highway from Mexico City to Acapulco are two of the principal means of access. The temperature is usually warm and during the month of November it varies between 24 and 30°C. (75-85°F)

PRELIMINARY PROGRAM

SUNDAY, NOVEMBER 12

Registration.
Meeting of the Executive Committee.
Opening ceremony.
Welcome cocktail.

MONDAY, NOVEMBER 13

First Round Table:
VALUE OF ELECTROPHYSIOLOGICAL DIAGNOSTIC TECHNIQUES IN CLINICAL ASSESSMENT OF AUDITORY DISORDERS.
(Moderator: Prof. Dr. G. Salomon, Denmark)

Invited Pannelists:

N. Yoshie, Japan; J.J. Eggermont, Holland; H. Sohmer, Israel; A. Starr, USA; M.E. Mendel, USA; C. Elberling, Denmark.

TUESDAY, NOVEMBER 14

Second Round Table:
AUDITORY REHABILITATION: PHYSIOLOGICAL ASPECTS.
(Moderator: Prof. Dr. W.D. Keidel, W. Germany)

Invited Pannelists:

F.B. Simmons, USA; K. Burian, Austria; A.C.-H. Chouard, France; T. Spillman, Switzerland; M.M. Merzenich, USA; P. Finkenzeller, W. Germany.

WEDNESDAY, NOVEMBER 15

Third Round Table:
AUDITORY REHABILITATION: PSYCHOLOGICAL ASPECTS.
(Moderator: Prof. Dr. P. Berruecos Jr., Mexico)

Invited Pannelists:

I. Nervi, Argentina; H.S. Lane, USA; T. Lundborg, Sweden; J. Rosenstein, U.S.A.; S.S. Stevens, U.K.; S. Borel-Maisonny, France.

THURSDAY, NOVEMBER 16

Free Papers
Free paper sessions will be held each afternoon during the first three days of the Congress, and in the morning of November 16. There will be divided into the following general subjects: Diagnosis and prevention; Research and Training Programs; Medical and surgical treatment; Rehabilitation and Special Education; Psychology of the deaf child and of the hard of hearing and Philosophical and Social Aspects of Audiology.

REGISTRATION

All the people interested in attending the Congress must send the enclosed registration form (Form "A") to the Organizing Secretariat (or to the OIC for European participants). All registered members will be able to take part in all the scientific, social and cultural activities of the Congress. The registration fee includes transportation in Acapulco. Registration fees for accompanying persons include participation in all social and cultural activities besides the ladies program.

The Organizing Secretariat has planned to send this first bulletin and subsequent information as follows:

- a) Audio Expo 78 bulletin: December, 1977
- b) Second bulletin: February, 1978
- c) Scientific program: May, 1978

HOTEL ACCOMODATION

The Organizing Secretariat has designated an official travel agency. It is necessary to send to the Organizing Secretariat (or to the OIC for European members of the congress), the registration form (Form "B"). The assignment of rooms will be made by order of arrival. Prices of the official hotels in Acapulco are the following:

HOTEL CONDESA DEL MAR (De luxe)	Single	US \$ 25.-
	Double	US \$ 29.-
	Triple	US \$ 39.-
HOTEL EL PRESIDENTE (First class)	Single	US \$ 20.-
	Double	US \$ 24.-
	Triple	US \$ 34.-
HOTEL FIESTA TORTUGA (Standard)	Single	US \$ 15.-
	Double	US \$ 18.-
	Triple	US \$ 23.-

or its equivalent in Mexican Pesos at the date of reception of all documents. All the rooms have private bath and are subject to a 4% federal tax.

A one night deposit must be sent with the reservation form. The Organizing Secretariat will not be able to guarantee the hotel rates if the reservations are received after March 31, 1978. All congress members that would like to have another type of accommodation or hotel rates must indicate so to the Organizing Secretariat without any compromise.

PAPER PRESENTATION

All persons interested in presenting free papers, must send the title with forms A and B and the registration fee, before March 31, 1978. The second bulletin will include all the instructions for the presentation of abstracts (deadline: May 31, 1978), and complete papers (deadline: August 31, 1978).

WORKING LANGUAGES AND SIMULTANEOUS TRANSLATION

The working languages will be Spanish, English and French. Simultaneous translation in these languages will be provided.

AUDIO-EXPO 78

A scientific, technical and cultural exhibition will be held in one of the halls of the Convention Center. The scientific participation and the cultural aspects of the exhibition will be detailed in the second information bulletin.

SOCIAL AND CULTURAL ACTIVITIES

This program will be offered to all the members of the Congress and accompanying persons. It will include a welcome cocktail, a Mexican Folkloric Ballet Show and the official closing dinner. An additional program for accompanying persons is being prepared. A visit to the diving show of La Quebrada, an exhibition of Mexican typical costumes and a general sightseeing of Acapulco will be included.

TRANSPORTATION

Transportation to all members and accompanying persons will be offered from the official hotels to the Cultural and Convention Center and viceversa as well as the transportation to all the social and cultural activities.

It will not be possible to offer transportation to those members lodged at different hotels from the official ones.

CANCELLATION

In case of cancellation of registration and hotel reservation that arrives to the Organizing Secretariat before August 10, 1978 will be refunded with a 25% less. Cancellation received after this date, will not be considered and it will not entitle to any refund.

XIV INTERNATIONAL CONGRESS OF AUDIOLOGY Acapulco, Mexico, 12-16 November, 1978

HOTEL ACCOMODATION

FORM "B"

This form and the one night deposit must be send by certified air mail to the Organizing Secretariat (or to the OIC for European Members). All cheques or postal money orders must be drawn to the XIV INTERNATIONAL CONGRESS OF AUDIOLOGY before March 31, 1978.

The Maico Series K. Choice of performance for mild to moderately severe losses.

The Maico Series K is more than just a collection of behind-the-ear hearing aids. It's an articulated concept of hearing aid design that offers excellent flexibility... an integrated system of complementary hearing instruments.

The Series K consists of three basic instruments — K210: ultra-soft performance, K220: non-directional amplification, K230: ultra-high frequency emphasis.

To each of these instruments the following options may be added:

- Choice of telephone switch or...
- User-operated Response Selector Switch to reduce low frequency background noise or...
- No external switching.

- Choice of three earhooks to suit the individual ear contour.
- Choice of two standard colors in all versions, light or dark skin tone.
- Either CRDS or B-CRDS available.

Once the desired options have been chosen the performance of the aid may be further adapted with two standard controls: a continuously variable low cut control, and a continuously variable output gain control.

And, unique to the Series K is Maico's exclusively designed, color-coded, easy-to-feel volume control with indexing that shows the amount of rotation at a glance.

The flexibility, performance, and quality of the Series K are worth investigating. For more information on the Series K, write Maico or call our toll free number, (800) 320-6366.

CORTI'S ORGAN

The Official House Organ of the American Auditory Society

Vol. 3, No. 3

July, 1978

Salute to Twenty Years of DRF

This issue of Corti's Organ is dedicated to The Deafness Research Foundation. For 20 years DRF has quietly and efficiently supported sound scientific research on the Ear and Hearing. An "American Auditory Society" should be the staunchest supporter of such an organization.

But organizations are made up of people who bring their distinctive styles to the functioning of the group. Two people in particular are contributing a particular flair to DRF: Mrs. Collette Ramsey, its founder and Mr. Ted Beck, its present Executive Director. They are featured in exclusive interviews with C. O. in this issue.

In addition, the distinctive nature of the research that is supported by DRF should be pointed out, because it is consonant with the aims of the A.A.S.

The Deafness Research Foundation has awarded grants to 32 research projects for 1978, the total dollar sum awarded representing the third highest in DRF history. The research projects are set at 25 institutions in 17 states and Canada.

The 94 applications received for these grants from medical centers and universities exceeds the record of 91 set last year. More striking, the general quality of the proposed and continuing research described in these applications was—in the judgment of the Scientific Review Committee members—the most impressive

that the DRF has ever seen. Had DRF funding resources been greater, considerably more projects would have received grant support.

Over half of the applications were for projects that were clinically oriented. Their proportional quality was as high, and over half of the grants are funding projects from this group. This demonstrates the advances in certain areas of otological research, where our basic knowledge now allows investigators to study its effective clinical applications.

Such advances give immense encouragement to otolaryngologists, to the other professionals involved with hearing and deafness, and to the millions of men and women who are intimately familiar with the diseases and disorders of the ear.

The following data give a general profile of the principal investigators on the research projects receiving 1978 DRF grants.

Principal investigator's degree:			
M.A.-1	M.D.-12	Ph.D.-19	
Principal investigator's age:			
26-30	1	41-45	5
31-35	14	46-50	2
36-40	9	50-	1

Principal investigator's department (overlapping for joint appointments): Otolaryngology

Continued on page 4

AAS Becomes the American Auditory Society

With this issue, the AAS changes its name to the American Auditory Society. The name change is incorporated in the new by-laws which were recently voted on by the membership. The result of the balloting is as follows:

To Adopt By Laws:	282
To Keep Original	
By Laws:	52
Inappropriate	
Mailings:	9
Abstention:	1
Total	344

The name change, plus the more flexible By-Laws, will allow the AAS to extend into all fields of inquiry and to allow a larger variety of disciplines to hold dialogue together.

This issue of Corti's Organ is addressed to prospective members of AAS. We want particularly to increase the numbers of otolaryngologists who are interested in the varied approaches to hearing that are represented in this organization. To this end we are simplifying the membership applications. All one needs to do is to send in the form on page 14, and the Society's secretary will obtain signatures from present members in the same geographical area.

So we urge all professionals, whether they be otologists or audiologists or psycho-acousticians, or linguistics, or engineers—if you care about hearing, join the American Auditory Society!

Collette Ramsey's Magnificent Obsession

Collette Ramsey
(Mrs. Hobart C. Ramsey)

The Deafness Research Foundation ("DRF") first began as a glimmer in the mind of a beautiful young woman who had been hard-of-hearing since age 13. Collette Ramsey was already mature beyond her years, with the maturity that comes from carrying the burden of a handicapping hearing loss—from having known as a youngster the frustration and isolation a hearing loss imposes upon its victims and how difficult it can make life for an otherwise healthy, normal young lady, wife and mother. Always in her mind must have been the thought, "If only a miracle could happen and I could hear..." This thought, growing in the brain of a deeply contemplative and quietly religious young woman, was the seed of a "Magnificent Obsession" that would help thousands of people afflicted with deafness.

In a recent interview, Collette Ramsey told Corti's Organ about her experiences:

C.O.: How did you get the idea of establishing the DRF?

Ramsey: It first solidified the day I learned that my hearing loss was due to otosclerosis and that there was now an operation that might help it. You can't imagine what it had been to have a sense of hopelessness all my life—to believe that I would never hear well and that nothing could be done about it. And then suddenly to learn that medical science had developed an operation that could help—it was like a great burden being lifted from my life that had been weigh-

ing me down. I was filled with a profound sense of gratitude. Right then and there I made a vow to myself that if this new surgery were successful in my case I would devote as much of my life as I possibly could to further the development of ear research. This was an agreement with myself that I was obligated to honor.

Q.: Tell us about the surgery?

Ramsey: That was in 1952, (the second ear in 1954), when Dr. Julius Lempert had perfected the fenestration operation. I was found to be a suitable candidate for surgery, and I asked him to perform it on me. The chances of improvement that were quoted to me were "two out of three" chances. That was good enough for me. I went in for the surgery eagerly and hopefully. At first I had the usual dizziness following surgery, but thank the Lord, when the packings and dressing were removed I COULD HEAR! I perhaps had as good a result from the fenestration operation as it's possible to obtain: from over a 60 dB loss to better than 25 dB. I heard sounds I'd never heard before and many that I'd long forgotten existed. At first it might have been bewildering or confusing if I hadn't been so enormously grateful to be able to hear well for the first time that I could remember! I was simply filled with gratitude that this miracle could have happened to me. Grateful that I had a conductive type deafness that could be helped by modern surgery rather than nerve deafness for which there was no medical or surgical means to restore hearing.

C.O.: And then you remembered your vow?

Ramsey: Indeed I did. That commitment was a private thing between myself and my Maker, but I have been mindful of it ever since. Actually it hasn't been "binding"—it has been a great joy and a source of deep inner satisfaction. Next to my husband and family, DRF has been the main-spring of my life. The help that already has come to thousands and the hope that lies ahead for millions of the deafened, as

Editorial...

On the occasion of the name change to **American Auditory Society**, Corti's Organ would like to pay tribute to some big-minded people in the organization. There was indeed a group—largely Audiologists—who felt that the term "Audiology Society" was not appropriate for an open membership society such as this. And we can understand the feeling of many—largely otologists and psychologists and psychoacousticians—that this attitude was petty and "picayune", to borrow our president's, Blair Simmon's, term. In addition to Blair there was Dix Ward, Aram Glorig, Jack Vernon, and our editor of JAAS, Don Harris—and all the otologists on the Board certainly—who felt the same way. Yet with great-mindedness they all refrained from making an issue out of the name change proposal. Indeed, they gave it tacit support by not opposing it and by allowing it to go through as a part of the By-Law Change. We want to acknowledge this group of members who were able to transcend pettiness themselves and thereby save the

I am trying to follow in the footsteps of the great Alistair Cooke whose world famous "Letters From America" have occasionally been written from England. My letter similarly will not be written "from England" but "from America".

Spring this year has reminded us strongly of England and it has been more like "rainy California"

Centurion Club Open to Professionals

DRF is unique among foundations in that its operational expenses are borne by a group of professionals called the Centurions. In the past the Centurion Club has been largely supported by otolaryngologists who have contributed \$100 annually to the Club. What has not been generally known is that it is also open to non-medical professionals at a reduced rate of \$25.00 per year. Thus, audiologists, psychoacousticians, speech pathologists, electronic engineers—indeed, anyone interested in the hearing field—can contribute to the support of his worthy organization. The payoff is the knowledge that all of the income from the capital funds of DRF can be devoted to its chief goal: the support of ear research. Many non-medical professionals have been the recipients of DRF research funds. It is time that this group lend its support to the Centurions. We urge every AAS member, whatever his interest, to become a Centurion by sending his \$25.00 to:

The Deafness Research Foundation
342 Madison Avenue

Sentac Meeting Announced

The annual meeting of the Society of Ear, Nose and Throat Advance, in Children (SENTAC) will be held at El Encanto, Santa Barbara, California on December 7 and 8, 1978. The deadline for abstracts for papers will be on June 15, 1978. Papers on 1.) Central Auditory Dysfunction 2.) The Effect of Moderate Hearing Loss on Language Development and Educational Achievement will receive preferential consideration. For further information, please write to Dr. Robin Cotton, Children's Hospital Medical Center, Elland & Bethesda Avenues, Cincinnati, Ohio 45229.

Society from what might have become a bad schism in its ranks.

So from the "picayunes": We salute you gentlemen and ladies and thank you for being the kind of people we want to continue to associate with in this organization. We hope you'll find the "Auditory Society" a little more comfortable to live with, as we believe, we will.

Saludos, amigos!-MPD-RJR

Letter from England

than sunny California. We came prepared for a heatwave and have brought our light weight clothing bought in Denver (Sears) last year, but we should have stuck to our British tweeds and woolies...

The weather has at least not distracted me and I have been able to concentrate on the real purpose of my visit: electron microscopy at the famous Ear Research Institute in Los Angeles. The Department has been developed to a very high standard of equipment offering excellent facilities which have not been fully exploited.

The Institute has kindly invited

me and Dr. P. G. Lundquist from Stockholm a renowned expert in this field and a fine surgeon whose advice will be of invaluable help for the future development of the department (now that its former director Dr. M. D. Graham has been lost to Ann Arbor).

I have been concentrating my interest on the apparently simple problems such as the ultrastructure of cholesterol granuloma and tympanosclerosis in addition to the ultrastructure of acoustic tumours (Schwann cell tumours of the ear) of which this place abounds. I have tried to 'smuggle'

in the otocyst which, I am sure, would serve as an excellent model for the study of the problems of innervation in conjunction with Bill House's famous investigations on cochlear implants.

There was a fine Conference on scanning electron microscopy in L. A. I have been able to attend in the company of a thousand participants, all keen types and enthusiasts. The exhibition was unusually interesting and one could have spent not only time but a great amount of money on useful equipment.

The Life and Times of Alfonso Giacomo Gaspar Corti

By Ross J. Roeser
Associate Editor

Most audiologists, otolaryngologists, and others who have studied auditory anatomy and physiology, when thinking of Corti remember him only for his organ; the organ of hearing that he is credited with first describing. Born June 22, 1822 near Pavia, Italy, the Marchese Alfonso Giacomo Gaspar Corti was the oldest son of the Marchese Gaspare Giuseppe Corti di San Stefano Belbo and the Marchesa Beatrice Malaspina di Carbonaro.

Ullman (1951) states that the Corti family had an old and impressive lineage. In fact, a young nobleman bearing the Corti name was present when the conqueror Henry II rode into the city of Pavia. Another Corti was a Ghibelline Castellan, and another a friend at court to Galeazzo, Charles IV's vicar. Another, Young Alfonso's grandfather, had taken up his sword against Napoleon.

Although many of the Corti family had fought in battle, most were fond of the arts and the pursuits of intellect. They were scholars, artists, and, often, physicians. In fact, in Pavia it was often said that all of the Cortis were "born to be physicians." Of Matteo Corti, physician to Pope Clement VII and Cosimo I and Professor of Medicine at Pavia, Pavia and Bologna, the historian Guazzo wrote that he could be compared only with the great Hippocrates and Galen.

But Alfonso's father had other plans than medicine for him. Instead of fostering his love for the natural sciences, biology, zoology, botany, and physics, the Marchese made him study the humanities. In this area his parents planned for him to add to the name of Corti and in doing so it would also enhance his mother's name as well. The Malaspini family had several noted historians in its past.

Corti probably spent his formal school years in Pavia, Italy, from 1841 to 1845, where he studied medicine. He was 23 years old when he left Pavia and set out by coach on a journey that was to last eleven years with numerous and frequent stops by the way. In September, 1845, Corti continued his studies in Vienna. Within a week or two he found that he could pursue his medical studies, visit the clinics on a daily basis as required, and still have time to pursue his fanatical interests in anatomy and physiology with the famed Dr. Josef Hyrtl. On August 6, 1847, Corti received his doctor's degree and at the end of December of that year he was chosen as Hyrtl's second prosector.

Ullman (1951) states that Corti's interest in the auditory system was initiated one afternoon when he was visiting with Dr. Hyrtl, when the great professor was gazing at a beautiful specimen of two crosscuts through the petrous bone. One of the crosscuts was through the cochlea and the other the labyrinth.

Upon questioning Hyrtl about the specimen, Corti was told that after spending fifteen years on the work that Hyrtl had barely scratched the surface on discovering how the ear worked. In fact, it was not even known what sections of the ear were responsible for hearing. Hyrtl did not even know if it was the cochlea or the semi-circular canals that was responsive to sound.

The real difficulty it seemed was that there was no way to view the inner ear before it perished. Before the specimen could even be put under the microscope it was only an indistinguishable mass of tissue and bone.

Following that day Corti began his studies with keen anticipation of an early discovery of the mechanisms of hearing. In his first endeavor he sliced the petrous bone of a freshly killed guinea pig and with his microtome, a tool just devised in 1847, working very fast in fifteen minutes. Upon examination he found a shapeless unrecognizable mass of decomposed matter. Alas, he probably thought to himself, the solution to the problem was speed. He must devise a way to view the delicate parts of the cochlea in less time. However, little did he know that this was not to be the answer to the riddle.

Due to the war that broke out between the Kingdom of Sardinia and Austria on March 23, 1848, Corti had to relinquish his position with Hyrtl and from February 2 to August 3, 1849 began his own microscopic studies in Bern with Gustav Gabriel Valentin. During this period he met some important microscopists including James Paget, Thomas Wharton Jones, and Richard Owen. From August 3, Corti spent the rest of 1849 with relatives in Paris.

In January, 1850, Corti began to work with Albert Kolliker in Wurzburg and mastered normal histology. His primary work was on the structure of the retina. He demonstrated the connection of the nerve cells with the optic nerve fibers through isolation, verifying A. H. Hossall's earlier disputed observations. He also completed several studies on the ciliary epithelium in the digestive organs of the larvae of frogs and toads.

Corti must have been occupying his time with studies on the inner ear while in Wurzburg, but had not completed them when he left in August, 1850. In that month he was invited to be a member of the wedding of his long time friend Rudolph Virchow in Berlin, and took the occasion to visit with Schroeder Van der Kolk and Harting in the Netherlands.

During the visit Harting, Corti, and three or four others were talking and in discussing the preservation of delicate specimens it was stated that to keep from dissolving, such materials must be suspended in fluid. When asked what fluid, Harting mentioned several: arsenic acid, distilled water with alcohol and sugar added, much diluted corrosive mercury, and a strong sodium chloride. However, he emphasized that Corti use diluted hydrochloric acid or acetic acid. Thus, Corti learned that the trick was not the speed of preparation, but suspension in fluid.

Back in Wurzburg, Corti set feverishly to work and in a few days had made his first significant observation on the cochlea. He described the complicated anatomy of the lamina spiralis in mammals. He saw that it carries bipolar globules 0.15 microns in size, the nature of which he supposed to be ganglions and which he assumed continued into the dark walled nerve fibers.

He was unsure only of how and where the fibers of the cochlea nerve ended, and was, therefore, unable to clarify the function of the individual parts of the membranous cochlea. Nevertheless, he expressed the ideas upon which Helmholtz based his "resonance" theory of hearing at a later date.

Corti completed his work in Paris. His work on microscopic anatomy was honored and he was elected to the Societe de Biologie de Paris (July 20, 1850), Verein Deutscher Aerzte und Naturforscher in Paris (April 5, 1851), and Paris Medical Society (April 5, 1851). The high point of his scientific career having passed, the death of his father forced him to leave Paris for Turin at the beginning of 1851.

A letter published in 1854 was to be the last time the scientific world was to hear from Corti. This letter concerns histological observations on an elephant and offers proof that the cells of various tissues of this large animal are of the

same relative size of similar cells of other mammals.

Corti was honored again in 1854 when he was elected to the prestigious Imperial Leopoldian-Carolinian Academy in January, 1854. In his letter of appreciation to the president of that society, Corti makes reference to the fact that he was suffering immensely from rheumatoid arthritis, causing him to become crippled in his hands and feet.

Although unable to pursue his professional interests, Corti developed a model farm for viticulture in an estate he acquired from his father in Mazzolino. In September, 1855, Corti married Maria Anna Carlotta Bettinzoli. Following the birth of their second child she died in 1861.

The remaining years of Corti's life were spent attending to the matters of his large and prosperous estate and educating his two children. At the age of 54 years Corti died. Due to the 22 years of silence preceding his death the scientific world was unaware of his passing.

Continued from page 1

secrets to deafness are unraveled through research, is a mighty rewarding experience to me.

C.O.: Yes, it sounds like a "Magnificent Obsession" of the highest degree. How did you go about fulfilling this commitment with yourself?

Ramsey: I asked questions and I listened. What a joy to be able to hear and to listen. I listened to many of the great otolaryngologists of our time. In addition to Dr. Lempert there were Drs. John R. Lindsay, Gordon D. Hoople, Lawrence R. Boies, George Von Bekesy, Ernest G. Wever and countless others. And I learned many things. First, that the government wasn't supporting any research to speak of in the field of otology at that time (1952-1954); and second, that there wasn't a single national voluntary organization in the country devoted to raising funds to support ear research. It was clear that there was a real void in this area in spite of the many duplications of effort and agencies for other health problems.

C.O.: A void that you set about filling.

Ramsey: Yes, with a lot of help from some wonderful people. I needed professional advice, and I got it from the excellent otologists I've mentioned. I needed business advice, and I got it, foremost from a wonderful husband who has backed me 100% in my goals. I could never have succeeded with the establishment and solid development of DRF, his patience and selflessness in allowing me to devote my entire energies to this cause.

C.O.: How did you go about it?

Ramsey: First I had to overcome the distasteful dread of meeting with people to discuss the need of financial support for otological research. This wasn't easy for a person who had been deafened since adolescence. But now the commitment I'd made outweighed any personal feelings—I had to succeed. So I mustered the courage, and faced a lot of very important people—presidents of large companies and foundations in the world.

C.O.: And with great success.

Ramsey: Well, we were ready to start by 1958. We awarded five research grants during that first '58-'59 year. One of them was to the A.A.S. founder, Aram Glorig, for his sub-committee on Noise of the O. & O., which we supported until 1967. Other grants were to Dr. Edmund Fowler, Jr., to Dr. Victor Goodhill, Dr. James Egan and Dr. Thamasa Stander.

C.O. What was the major thrust of the support?

Ramsey: From the beginning

2nd International Elks Conference

Another highly productive conference on early detection convened in Saskatoon, May 7-9, sponsored again by the Elks Clubs of Canada. In actuality it was the 3rd International Canadian Conference on this theme, as Dr. Hallowell Davis pointed out in his keynote address to the meeting. The first one was sponsored by

Mr. Fox of Toronto, a great philanthropist in the hearing field, and the proceedings appeared as a Supplementum to Acta Otolaryngologica in 1965. But the present meeting is the second sponsored by the Elks Clubs of Canada, who initiated the international concept in 1974 at Halifax, Nova Scotia. The proceedings

were published in 1975.

As Dr. Davis has indicated, the value of such conferences is the immediate dissemination of information that would ordinarily take two years to get into the literature. In Saskatoon the emphasis was on Brain Stem Evoked Response Audiometry (BERA) as the newest and most reliable

means of measuring infants' hearing. The foreign experts who discussed a wide range of approaches to testing infants included: Dr. John Bench of Reading, England; Dr. Mordecai Himmelfarb of Jerusalem, Israel; Dr. Jean-Marie Aran of Bourdeaux, France; Mrs. Lilly Tell of Jerusalem, Israel. North Americans included: Dr. George Mencher of Halifax; Dr. Burton Jaffe, of Boston; Dr. Martha Rubin of New York City; Dr. Don Worthington of Boys' Town in Omaha; Dr. Terry Pictin of Toronto; Dr. Robert Galambos of San Diego; Dr. Maurice Mendel of Santa Barbara; Dr. John M. Moore of Seattle; Dr. Sanford Gerber of Santa Barbara; Marion Downs of Denver and Dr. Hallowell Davis of St. Louis.

infants who had recurrent MEE. If the effusion is incurred for 3 months or more, the conference recommended both medical and educational intervention.

The conference was concerned that medical schools are not educating medical students about the importance of early identification of hearing loss and also the availability of means of testing infants. A strong recommendation was made for schools to incorporate such teaching.

Screening of hearing at 5-7 months of age was recommended for all baby clinics and doctor's offices. The use of noisemaker tests, VRA tests or any other means was urged.

High concern was expressed for the role of the parents in early identification. Family ties are vitally important, so full evaluations should be made early of any suspected child, in order to allay parental anxiety. Parents' concern over a possible hearing loss should occasion immediate audiological referral by a physician, and parents should be involved in all the diagnoses and the educational management plans for the child.

A highlight of the meeting was an occurrence that became the joke of the conference. Dr. Burt Jaffe's seat mate on the incoming plane was a gentleman, to whom he introduced himself, "I'm Burt Jaffe", and the man said "I'm the Canadian Minister of Transportation"—to which Dr. Jaffe replied in an aside, "and I'm the President of the United States". It turned out that the gentleman was indeed the Canadian Minister of Transportation, who later hosted a cocktail party for the Conference participants. The story was regaled with great delight at the party. A picture of the Minister with Jaffe and Coulling is shown herein on page 5.

TOTAL 1978 Research Grants 32

(Please note: The "categories" above represent general labelling for the projects, many of which would fit as accurately under one or two other headings).

A brief summary of each grant project follows.

1978 DRF Research Grants General:

Auditory Deprivation

Richard J. Salvi, Ph.D. State University of New York-Upstate Medical Center. "The Effect of Auditory Deprivation on the Olivary Nuclei" (1st yr).

A study of the electrophysiological effects of the absence of sound for 3-5 months on baby animals, this project concerns a problem of major importance in relation to the factors determining normal or abnormal development of hearing in infancy.

Immunodiagnosis

Lee A. Harker, M.D. University of Iowa. "Immunodiagnosis of Acoustic Neuroma" (2nd yr).

Using the leukocyte migration inhibition assay, the project appears to be establishing a simple but highly accurate method for early diagnosis of Schwann cell tumors, their presence, recurrence and rapidity of growth.

Noise, Ototoxicity

Richard P. Bobbin, Ph.D. Louisiana State University Medical School. "Interaction of Noise with

Two Reversibly Ototoxic Drugs" (1st yr).

A study of the basic mechanism of sensory cell damage after exposure to intense noise and toxic drugs, the project is also investigating the dampening effect of two drugs on noise damage when they are taken before exposure to intense sound.

Vijay S. Dayal, M.D. University of Toronto. "Study of Potentiating Harmful Effects of Low Level Noise & Kanamycin on Guinea Pig Cochlea" (3rd yr).

This project has already determined that inner-ear cell damage occurs after lower levels of noise and of toxic drug dosage than had been realized; the investigator is also seeking to find whether young and old animals are equally vulnerable.

Gregory J. Matz, M.D. University of Chicago. "Progressive Neurotoxicity of Kanamycin" (2nd yr).

The project is developing an animal model for accurate pathological study of early and delayed changes in the cochlea, or inner ear, after exposure to a toxic drug, and for finding whether these changes are associated with reversible hearing loss.

Michael J. Mulroy, Ph.D. University of Massachusetts Medical School. "A Scanning Electron Microscopic Study of Cochleas with Noise-Induced Losses in Sensitivity" (2nd yr).

An ultrastructural study of the hair cells in the inner ears of animals who show permanent insensitivity to narrow ranges of noise after prolonged moderate exposure to those ranges, this project should lead to a precise understanding of one aspect of noise damage upon the cochlea.

James C. Saunders, Ph.D. University of Pennsylvania. "The Physiological Consequences of Noise Exposure in Young Animals" (1st yr).

This project is studying the critical period after birth when the hearing mechanism is acutely susceptible to trauma when exposed to intense noise.

Rehabilitation

Rebecca E. Eilers, Ph.D. Mailman Center—University of Miami. "Tactual Perception of Speech and Speech-like Stimuli: A Sensory Aid for the Deaf" (1st yr).

To enable the development of an effective device that can transmit sounds as vibrations sensed by the skin for people who cannot be appreciably helped by hearing aids, this project builds upon a procedure for transforming speech energy into intelligible

patterns of tactual stimulation.

Sudden Hearing Loss

William R. Wilson, M.D. Massachusetts Eye & Ear Infirmary. "Idiopathic Sudden Hearing Loss. A Prospective Study" (2nd yr).

The investigator has already evaluated 35 patients with sudden hearing loss of undetermined cause, a frightening kind of deafness with no consistent, effective therapy. The large number who are under 40 years reinforces the correlary research into possible viral causes.

Tinnitus

Clarence T. Sasaki, M.D. Yale University. "Tinnitus: The Development of a Neuropsychologic Correlate" (1st yr).

With tinnitus the most maddening, common and poorly understood of all ear disorders, this project aims toward creating an animal model effective for the study of the nature of tinnitus its possible causes, and the most useful kind of treatment.

Virus Infection and Deafness

(Continued on page 6)

Collette

Continued from page 3

DRF has given broad support for all aspects of ear research with major emphasis on nerve deafness. Most often DRF has awarded "seed money" grants to promising young investigators undertaking new research projects. Most of the investigators, usually under age 40, have had no other financial support to speak of when they receive DRF's first grant. (Usually limited to a three year promise of support). By the end of the second or third year of DRF support a high percentage of projects initiated by DRF seed money grants progress

Collette Ramsey in her favorite disguise.

Inter-Noise 78 Proceedings Published

A 1088-page volume, "Designing for Noise Control," has been published and is available to those concerned with environmental noise and its control.

"Designing for Noise Control," the Proceedings of the 1978 International Conference on Noise Control Engineering contains the papers presented at INTER-NOISE 78, sponsored by the International Institute of Noise Control Engineering and organized by INCE/U.S.A. The Conference Secretariat was the responsibility of Noise Control Foundation.

More than 800 engineers and other individuals concerned with noise control attended INTER-NOISE 78 which was the first INTER-NOISE Meeting held in California. The previous six INTER-NOISE Conferences have been held in Washington or overseas. The theme of INTER-NOISE 78 was "Designing for Noise Control."

The 1088-page book of Proceedings, edited by Conference Chairman William W. Lang, contains papers covering all branches of

noise control, in-plant noise control, transportation noise control, instrumentation and analysis techniques for noise control, and building noise control.

One of the highlights of the Conference was a series of five Distinguished Lectures on several aspects of noise control. These special lectures were: "Facts and Values in Noise Control" by Richard H. Bolt; "Noise Reduction by Design" by Richard H. Lyon; "Standards and Criteria for Noise Control" by Kenneth M. Eldred; "Uses of Sound Power Level" by Peter K. Baade and "Impact Noise from Industrial Machinery" by E. J. Richards. These special presentations highlighted the theme of the Conference; the text of each paper has been included in the Proceedings.

Copies of the INTER-NOISE 78 Proceedings are available from INTER-NOISE 78, P. O. Box 3469, Arlington Branch, Poughkeepsie, NY 12603 U.S.A. The postpaid price is \$35.00. Overseas orders must include \$7.00 extra if shipment is to be by air.

The Second International ELK'S Conference

Bob Galambos, San Diego, and Maurice Mendel, Santa Barbara.

Mick Moore, Seattle, with John Bench, England.

Hallowell Davis, C.I.D. and Martha Rubin, Lexington School for the Deaf, N.Y.C.

George Mencher of Halifax and Bob Cooling, Elk's Club of Canada.

THE ISRAELI CONTINGENT: George Mencher (currently on Sabbatical in Jerusalem); Mordecai Himmelfarb, otolaryngologist from Hadassah Hospital in Jerusalem; and Lilly Tell, audiologist from Hadassah Hospital in Jerusalem.

Burt Jaffee, Boston; Bob Coulling, Elk's Clubs of Canada, with The Canadian Minister of Transportation.

Bob Galambos with Mrs. John Bench, England.

Don Worthington of Boy's Town, Omaha; Lynn Brewster, arranger of the Conference; and Mick Moore, Seattle.

Burt Jaffee, Boston, with Jean-Marie Aran of Bourdeaux, France.

Terry Pictin and Canadian representative.

A Minority Report of the Impedance Task Force

(Editor's note: In our last issue we published the Recommendations for Impedance Testing of the Task Force of the Vanderbilt Symposium. A substantial minority of the Task Force (almost 20%) disagreed with the majority vote, and have submitted the following letter to the editor to register this protest.)

Letter to the Editor:

The Task force from the Symposium on Impedance Screening for Children (Nashville, 1977), exerted an enormous amount of time, effort and energy in their formation of Recommendations for impedance screening. However, consensus was not reached on all issues and we believe that

the final recommendations clearly demonstrated the old adage that "... a camel is the result of a committee trying to design a horse". We do recognize that the final product represents many vested interests from several professional points of view concerning impedance screening and ear disease. It is our intent in this letter to the editor to express viewpoints of some members of the Task Force which were not included in, or are at odds with, the final set of "Recommendations From the Task Force."

First, and foremost, we oppose the Task Force statement that "At the present time, and until additional information has been developed, the Task Force does

not recommend the use of impedance measurements for universal (mass) screening on a routine basis for the detection of middle ear disorders in children of any age group". This statement becomes a blatant contradiction when one considers that the Task Force report also states that middle ear effusions are a prevalent condition among infants and children, and that evidence exists that "early treatment may be of advantage in preventing certain unfavorable long-term developmental consequences in some children—". Clearly, the recommendations are phrased in such a way as to act as a deterrent to the early identification and management of this prevalent

disease, it is incongruous that a set of referral criteria and other guidelines for impedance screening are presented by the Task Force, but at the same time identification by impedance screening is explicitly discouraged. It is our contention that this position has been taken, not because the impedance screening procedure lacks validity, but because there is considerable uncertainty about medical management of the identified pathologic condition.

We understand and acknowledge that middle ear effusions are frequently transient and self resolving, a situation which has contributed to overreferral in screening programs. However, at the same time we are of the opinion that sufficient information presently exists to formulate specific referral criteria which would consequently make it viable to utilize impedance screening as a public health measure. While we did not urge the Task Force to advocate impedance screening as an essential screening procedure, we believe it is a reasonable procedure given the appropriate guidelines and referral criteria.

We do acknowledge the fact that additional research is needed before mass impedance screening can be advocated. Much of the data which was considered by the Task Force was obtained "clinically" rather than in screening programs and was, therefore, not truly representative of the population of children for whom screening measures are intended. In addition, the radical change in impedance instrumentation during the last several years promises to result in even more effective screening, but this has yet to be established. Nevertheless, at the same time, we support, rather than discourage, the use of impedance screening as a means of

increasing the wealth of information which would be generated only through a variety of screening programs.

We also fault the Recommendations because there is no category for initial screening failure and referral. The Recommendations state that "... any child failing the initial (impedance) screening should be retested in four to six weeks." We support the concept of monitoring or retesting as an essential component which will minimize over-referrals in impedance screening programs.

However, we do not agree that a child with a "non-mobile" TM or "flat" tympanogram, with an absent acoustic reflex on the initial screen should wait a period of four to six weeks before a repeat test confirms the persistence of pathology. Such findings on initial screen should be cause for immediate referral and medical evaluation. They also should be the cause for implementing more careful hearing testing and appropriate educational considerations.

In summary, we recognize the need for impedance screening guidelines, and the Nashville Symposium certainly provided the appropriate impetus for Task Force discussions. However, we feel that the final recommendations did not reflect the consensus of the Symposium participants. We hope our few words will kindle rethinking of the issues.

(continued from page 4)

Melvin Strauss, M.D. Pennsylvania State University-Hershey Medical Center. "A Clinicopathologic Study of the Relation between CMV infection and Congenital and Acquired Deafness" (3rd yr).

With studies of temporal bones and of umbilical serum specimens, this project will produce important information on a causative relationship between Cytomegalovirus infection and deafness.

Middle Ear:

Physiology

G. O. Proud, M.D. University of

Dues Increase Announced

The AAS Executive Committee recently voted a \$4.00 increase in dues beginning January, 1979, bringing dues to \$29.00 per year. The reason for the increase was increased costs of the *Journal of the American Auditory Society*.

With the ratification of the new By Laws, future changes in dues will be voted on by The Society Membership, rather than the Executive Committee.

Kansas Medical Center. "Function of the Tympanic Plexus Chorda Tympani Nerve as Related to Parotid Gland Secretion" (1st yr).

Examining the effects of stimulation and staining with horseradish peroxidase upon nerves of the tympanic plexus, this project is aimed toward finding a way to prevent or relieve "mistaken regeneration of auriculo-temporal nerve after injury."

Middle Ear Infection and Disinfection

Robert M. Bunsted, M.D. University of Iowa. "The Study of Mechanisms of Bone Resorption in Chronic Ear Disease" (1st yr).

Using immunological and culture methods to study the processes of bone destruction in chronic otitis and cholesteatoma, this project may indicate clinical modifications that could prevent some of the complications associated with these conditions.

Daniel M. Lewis, Ph.D. Ohio State University. "Experimental Otitis Media" (2nd yr).

This project involves the development of an animal model for

Continued on page 7

NICOLET CA-1000...

for evoked response measurements in situations where the use of conventional behavioral audiometry is not practical.

Evoked response measurement protocols are especially useful for patients who are unable to accurately describe their sensory experiences because they are infants, retarded, comatose, suffer neurological disorders or are normal, but anxious.

Auditory evoked response measurements involve the use of click or tone burst stimuli (at various intensities, rates, durations and frequencies) which are used to noninvasively record electrical activity along the auditory pathway.

Some typical applications include:

- Brainstem auditory evoked responses using click stimuli for hearing evaluations, to determine conductive versus sensorineural hearing loss and to localize acoustic tumors, demyelinating disorders and vascular lesions.
- Middle or late latency components measurements using tone burst stimuli to check specific cortical responses over a wide range of frequencies.
- Electrocochleography using click or tone burst stimuli to evaluate conductive hearing loss.

The result of an auditory evoked response measurement is a precise waveform where the elements of interest are the amplitude, latency and morphology under known stimulus conditions giving the clinician a valuable tool for diagnosing hearing problems.

The CA-1000 is a complete portable system including stimulus generators, acoustically shielded headphones, recording electrodes, preamplifier, signal averaging computer with built-in oscilloscope display including accurate numerical readout of latency and amplitude, recorder for permanent records and a convenient equipment cart.

For complete details on the CA-1000 system or to arrange a demonstration please phone or write Nicolet.

Marion Downs Honored in Ceremony

Marion P. Downs, M.A., Audiology Clinical Director at the University of Colorado Medical Center, Colorado General Hospital, was awarded the coveted University of Colorado Gold Medal for recognition of her services to the University. The award was presented to her during the Spring Commencement and was accompanied by the following citation:

MARION P. DOWNS, Associate Professor of Otolaryngology, is an exemplary clinical audiologist who has devoted her life to helping those handicapped by deafness, and teaching those who would be in contact with deaf people to have a better understanding of hearing impairment.

During her outstanding career at the University of Colorado Medical Center Mrs. Downs pioneered, developed and evaluated techniques for testing hearing in children. She is noted internationally for her work in the area of early identification of hearing loss and in infant hearing screening. Her publications and teaching have brought world-wide attention to the importance of early habilitation for deafness, and alerted the medical world to the developmental problems associated with childhood deafness.

Mrs. Downs is an outstanding teacher and prolific writer, and no student of hearing disorders can

Marion Downs

pass through coursework without being influenced by her contributions. Thousands of patients, especially grateful for her concern and wisdom have benefitted from her devoted effort to better their lives.

For recognition as an outstanding educator, clinician, author and progressive advocate for the hearing-impaired, Mrs. Downs has been honored by her professional colleagues and peers. Today, in continued recognition of a warm, sensitive human being concerned with the betterment of life for those handicapped by deafness, it is with great affection and pride that the Board of Regents of the University of Colorado honors Marion P. Downs by awarding her the University of Colorado Medal.

Mrs. Downs holds ASHA certification in Audiology, is a Fellow of the Association and has been very active in state, national and international audiology activities.

Continued from page 6

media, by which to study the relationships between infection and local or systemic immune response with a precision that will enable us to determine the best method for immunization.

Inner Ear:

Auditory Physiology
Alfred C. Coats, M.D. Methodist Hospital (Houston). "Electrophysiological Approximation of the Pure-tone Audiogram" (3rd yr).

The investigators have impressively designed and are now testing an objective audiometer. The program and instrumentation will enable accurate evaluation of patients who cannot respond to the usual forms of audiologic measurement.

Jerry L. Cranford, Ph.D. Baylor College of Medicine. "Role of Auditory Cortex in Higher Association Hearing Functions" (2nd yr).

In this basic research into the role that the brain's ability to associate has in normal hearing perception, the investigators have already noted significant degrees of neural plasticity that have allowed animals without neocortices to learn non-auditory cues to govern their response to tone pulses.

David J. Lim, M.D. Ohio State University. "Tectorial Membrane-Sensory Cilia Relationship" (3rd year).

This study of the development of the tectorial membrane and its

relationship to the inner and outer hair cells in the Organ of Corti has progressed very well, governed by the investigator's intention to clarify the mechanisms involved in sound transduction.

Jochen Schacht, Ph.D. University of Michigan. "Biochemical Mechanisms in Auditory Transduction" (3rd yr).

An effort to define the biochemical element in transduction, in this clarifying how sound vibrations are turned into nerve impulses in the inner ear, the project has already shown, e.g., that pulsed tones increase the labelling of phosphoproteins more than continuous tones do.

David Strelhoff, Ph.D. U.C.L.A. "Acoustic and Electric Biasing of the Whole Nerve Response" (1st yr).

A significant inquiry in the field of cochlear electrophysiology, this project changes the electrical environment of the guinea pig cochlea, to study its effect upon the whole nerve action potential as recorded through intracochlear electrodes.

Cochlea

William E. Brownell, Ph.D. University of Florida. "Functional Differences between Inner and Outer Hair Cells" (2nd yr).

In a project concentrating upon the site in which transduction occurs, the investigator is now concerned with studying the differences in tracer substance uptake in the inner cells and in the outer cells.

Mary B. Meikle, Ph.D. University of Oregon-Health Sciences Center. "An Animal Model for Electrical Stimulation of the Cochlea" (3rd yr).

In this important effort to establish a valid animal model to evaluate—through single-unit responses—electrical stimulation of the cochlea, the investigator has established the difficult guinea pig as a fully suitable model, and has finished mapping the specific zones corresponding to the turns of the cochlea.

Electrophysiology

John D. Durrant, Ph.D. Temple University. "Studies of the Cochlear After-Potential" (2nd yr).

The investigator has already worked with 17 animals, the initial results giving a clearer understanding of the complex make-up of the action-potential; its peak, e.g., is reached at the instant sound has completely stopped, not at the moment it begins to stop.

Embryology and Genetics

Peter Heywood, Ph.D. Brown University. "Selected Ultrastructural Aspects of Inner Ear Development in the Guinea Pig" (2nd yr).

A study (also cytochemical) of certain aspects of cochlear development in the fetus, this project will contribute considerable information on the development of hair cells, their innervation, and the

The first Honors Award of the Louisiana Speech and Hearing Association has been presented to **Dr. Jeannette K. Laguaite** of Tulane Medical Center, who held the position of director of the Center from 1952 until last year. The award is the highest honor bestowed by the 60-member state organization of audiologists and speech pathologists.

The National Association of the Deaf has established an Ad Hoc Committee to study and recommend procedures for the establishment of a universally acceptable symbol for deafness. Suggestions may be submitted to NAD offices at 814 Thayer Ave., Silver Spring, MD 20910, 301-587-1788.

Dr. Elda Dossena, Vice Presi-

dent of Amplaid, U.S.A. Inc., has announced the appointment of Jan De Benedetto as National Sales Director and Mario De Palo as Application Engineer.

Oticon has recently held dinner-meeting seminars as part of a nation-wide educational tour program for hearing health care professionals. **Jorgen Heide**, Director of Technical Sales and Information, presented programs on Hearing Aid Technology; Fitting and Modification of Aids; Research and Development and Product Features. The entire Oticon inside sales staff hosted the seminars and provided support.

The infant teacher training staff of the **Lexington School for the Deaf** announces the availabil-

ity of fellowships for professionals interested in working with deaf infants and their parents. The Specialized Infant Training Fellowship is offered at the Lexington School for the Deaf in New York City to prepare profes-

sionals to work with deaf infants and their families. The five-month, full-time training program focuses primarily on the hearing-impaired child's developing speech, language, and affective development, and on understanding the parent's role throughout the early childhood years. For further information write to Infant Teacher Training, Lexington School for the Deaf, 75th Street and 30th Avenue, Jackson Heights, New York 11370.

Salute . . .

nature of the membrane-bound cells of the vestibule.

William F. Marovitz, Ph.D. Mt. Sinai School of Medicine-New York. "Otic Differentiation" (2nd yr).

This project is studying the development of normal and

abnormal otocysts in the fetuses, in this concentrating on surface antigens, e.g., as possible causative factors in aberrant growth.

Thomas Van de Water, Ph.D. Albert Einstein College of Medicine-New York. "Fate Mapping of the Mammalian Otocyst in Vitro" (3rd yr).

Having completed the time-lapse mapping of the normal mouse otocyst in live culture, the project is now mapping the growth of one kind of mutant otocyst, as a first model for abnormal development; these delineations of the sites of origin of the various sensory structures of the embryonic inner ear provide remarkable evidences for the study of congenital deafness.

Histopathology

Joseph B. Nadol, Jr., M.D. Massachusetts Eye & Ear Infirmary. "Electron Microscopy of Human Inner Ear" (3rd yr).

This electron microscopic study of the temporal bones from people with normal hearing and with various kinds of nerve deafness should provide important ultra-structural information on what actually happens in the inner ear, especially when combined as this is with sound clinical and audiological data for each donor.

Implant

Richard A. Walloch, Ph.D. University of Oregon—Health Sciences Center. "Behavioral Evaluation of Scala Tympani Implants in Cats" (3rd yr).

Having implanted the multi-channel electrodes in the cochleas, the investigator has increased the sensitivity of the behavioral controls on the limits of electrical stimulation and is now concerned with the crucial demonstration of latency differences for changes in frequency in the stimulation.

Neuroanatomy-Neurophysiology
John R. Boston, Jr., Ph.D. Carnegie-Mellon University, University of Pittsburgh. "Receptor Potentials and Neural Response in Acoustico-Lateralis Sensory Cells" (3rd yr).

Aimed at clarifying the effects of noise and drugs on the transduction process as a way toward understanding the neural coding in this process, the project's technical goal is to relate the microphonic responses of hair cells to single-unit responses through a simultaneous recording.

Eileen S. Kane, Ph.D. University of Massachusetts Medical School. "Identification of Neurotransmitters in the Lower Auditory System of Mammals" (1st yr).

A broad, sophisticated study of the problem of neurotransmission and the development of nerve synapse in the cochlea; the project should help us understand how auditory information received in the peripheral cochlea is processed at its nucleus.

Michael J. Lyon, M.A. State University of New York—Upstate Medical Center. "Central Connections of the Stapedius Muscle of the Cat" (2nd yr).

Directed toward locating, enumerating and studying the motor neurons in the brainstem which supply the stapedius muscle in the middle ear, this pro-

HEARING...

Audiotone's dedication to the Hearing Impaired

The Human Ear performs one of man's most demanding functions—Listening. So when a hearing loss affects listening and a hearing aid is needed, only the best is good enough.

Audiotone has made a commitment to produce the highest quality hearing aids possible. To insure lasting performance, only the finest, most durable materials are used. Each component is thoroughly tested before passing a demanding system of quality controls.

Since 1949 Audiotone has served the needs of the hearing impaired. Such technical advances as Audiotone's CUSTOM FITTING and MULTIPLE ADJUSTMENTS hearing aids help the hard of hearing enjoy a fuller, more active life.

And that's something we're very proud of.

A recommendation you can depend on.

Meet Ted Beck DRF's Executive Director

He's the kind of guy you'd like to sit down and have a beer with—or take to a football game. But ask him about Ear Research and he's off and running. In the short time he's been DRF Executive Secretary Ted Beck has learned all about deafness, about what will most help people who are deaf, and about the kinds of information professionals need to fight deafness. And he talks about it with an engaging enthusiasm that stems from a love of people and ideas.

It's his energy that engages people with him—both his physical and mental energy. The ideas keep bubbling up, as he tries them out on you, and you become as rapt with them as he is. During a fairly brief tenure he's produced a top-notch newsletter (the Receiver) and put out some excellent information pamphlets. And kept up a constant flow of announcements and promotional material.

Ted Beck became Executive Director of the DRF in November 1976 after a dozen years as an English professor at the University of Nebraska. Exeter prep school and Princeton University were his schools. For a New Yorker coming home, it was a new career prompted by a family illness, but the thought of a "DRF-kind" of work had started long before.

Corti's Organ asked Ted Beck to fill in these details:

C.O.: What got you interested in hearing?

Beck: When the youngest Beck, after a non-stop sequence of infections, was found to have a substantial hearing loss, Lewis Mack—whom I had known since childhood—wrote that we should see Marion Downs immediately. We didn't; Ed Stivers handled the

Ted Beck

son very well in Lincoln. But from Lew Mack, I heard a full story on hearing specialists and, in 1976, on the DRF.

C.O.: When you joined DRF it had been well established but was attempting to expand in several directions. How did you fit in here?

Beck: I knew something of such growing pains at Nebraska, where I helped start the special residential college at the University and later became its dean. (One of my students is now beginning her ENT residency at NYU).

But the Triological, Otolaryngology, Meniere's disease and hair cells have all been news to me. Thanks to Harry Rosenwasser—DRF Director of Medical Affairs—total ignorance does not last long, not if the Receiver articles are to get safely past the eyes of professionals. And here Wesley Bradley has been a rare tutor and guide.

C.O.: How do you see the challenge to DRF?

Beck: Deafness has been a low spot on the totem pole of public estimation, the public unaware of the frustration known by physicians and audiologists when they meet yet another patient with sensorineural hearing loss.

Part of the DRF challenge is to help in this wakening. Part is in providing a way for professionals and lay people to work together in service, public education and in research support.

I have found two prime virtues of the DRF in its Centurion Club and in its tough scientific objectivity. The first has introduced me to a company of men and women in one field of medicine whose active service for an organization unattached to their hospital or clinic establishes the generosity of their commitment.

The second—the wise governing of the competition for the DRF research grants—has several roots, least visible in the anonymous Scientific Review Committee, most obvious in the quality of the physicians on the DRF Board and in the close relationship the DRF has had for years with the NINCDS at the National Institutes of Health.

C.O.: What is the outlook, as you see it?

Beck: In the last 18 months, ten new directors have joined the DRF Board, a Development Committee—chaired by George Ball, the young president of E. F. Hutton—is mapping new directions and strategies, and

then acting on them, and the DRF is struggling to build state and regional chapters.

In the last year, I've worked with Marion Downs and Gerry English on trying to start a DRF chapter in Colorado, with K.J. Lee and Frank Riccio on the same in Connecticut, and with Mrs. Robert Seamans, Bill Wilson and Harold Schuknecht in Massachusetts. I've worked closely with George Nager—meeting a host of lab directors—on the Temporal Bone Banks Program for Ear Research. Through an office foisted on me I have been very much engaged—with Jim Snow—in the "National Committee for Research," the coalition of voluntary organization and professional societies that supports the NINCDS. And thanks to Jim Spencer and Gene Burton of NAHSA, the DRF—hopefully—will be serving Lions International closely and well through the network of temporal bone banks.

But I see deafness, and otological services and research, most in need of national awareness, public support and public dollars. At the June meeting of the DRF

Board, three new directors were elected: Marion Downs, who represents several fields; Ernest Weymuller, a New York model of the otolaryngologist in private practice who is not distracted from wider service; and Gertrude Galloway, President-elect of the National Association of the Deaf.

The strength of the future for deafness—and for the professionals who serve those with hearing and speech disorders—promises to be in the conjoining of men and women, patients and families and professionals, of organizations, so that one common goal is powerfully sought together.

Dr. David Lilly, a positively brilliant and happy (from his expression) speaker.

Amplaid's International Immittance and Evoked Response Symposia

"The greatest success obtained by the two recent Symposia in Audiology organized by Amplaid" comments A. C. Holland, who opened the works in Milan, Italy as President of Amplifon C.R.S. co-sponsoring these activities, "is probably due to the new formula attempted: combining under one main topic two objective audiometry techniques: research and clinical application, today and in the future."

Hosted by the Amplifon C.R.S., the Amplaid Symposia were held in Milan from May 10th to June 2nd. Dr. David Lilly, of Iowa Uni-

versity, was the guest speaker at the 2nd International Symposium on Clinical Acoustic Immittance Measurements. Standards, research, prediction techniques, the diagnostic value of acoustic reflex measurements and reflex decay were brilliantly presented to a multinational group of experts that contributed to a most interesting and stimulating discussion.

A group of world-known speakers, Dr. A. Antonelli, Milan E.N.T. University; Dr. E. Biondi and F. Grandori, Milan Electroneurology; Dr. J. J. Eggermont, Leiden E.N.T. University;

Dr. C. Elberling, Gentofte Hospital, Hellerup; Dr. G. Salomon, Gentofte Hospital, Hellerup, and Dr. A. R. D. Thornton, Institute of Sound and Vibration Research, Southampton, presented, at the 3rd International Symposium on Auditory Evoked Responses, the results of their research and studies and of their further analysis of auditory electrical potentials recorded both in normals and in subjects of various known pathologies, thus making available the maximum amount of clear-cut differential data for the benefit of the clinical user.

The speakers at the Auditory Evoked Responses Symposium: from left to right: A. C. Holland; Dr. G. Salomon; Dr. A. Antonelli; Dr. F. Grandori; Dr. J. J. Eggermont; Dr. C. Elberling; Dr. A.R.D. Thornton.

Salute...

ject has general importance for our understanding the information developed from impedance audiometry on the role of that muscle and its alterations in otoneurological disorders.

Edwin W. Rubel, Ph.D. University of Virginia. "Acoustic Stimulation and Brain Development" (3rd yr).

This project has made considerable progress in its experiments directed toward finding out how known amounts and frequencies of auditory experience in young animals affects the development of structural and functional properties in the brain stem auditory centers.

Sensori-neural Deafness

Tetsuo Morizono, M.D. University of Minnesota. "Experimental Hypercholesterolemia and Hearing Loss" (1st yr).

The primary aim of this project is to determine the precise nature and degree of high-cholesterol dietary involvement in the development of atherosclerosis and high-frequency hearing loss; it will also provide secure audiologic and pathological data on the possible reversing effects on hearing loss of a low-cholesterol diet after an animal has been fed a high-cholesterol diet for a set period.

Book Reviews

SCIENCE, Vol. 200, No. 4344, May 26, 1978

Are we really going to have a National Health Insurance Plan? What form will it take? Are doctors practicing more defensive medicine because of escalating malpractice suits? What can the government do to control malpractice suits? Is PSRO here to stay? How far is medicine responsible for preventive health care?

These and other relevant questions are answered rationally and intelligently in a special issue of *Science* devoted to Health Care. The editors have chosen their authors and topics selectively to reflect the best opinions available on the current health care controversy. Its relevancy is indicated in an overview showing that the "health industry" accounts for 9% of the gross national product and is one of the three largest industries in the nation. But the likelihood of a comprehensive government-owned and operated system like those in European countries is very low.

What is advocated here is national health insurance which should be an "aggressive buyer of health services" rather than a mere insurer that protects people against the cost of medical care.

For example, the national health plan would seek out, without any barrier of copayment, inexpensive personal health services that have been demonstrated to be cost-effective such as immunizations, pre-natal care, contraception, and various screening tests for groups at High Risk. (Note: one would hope that hearing tests for children AT RISK for hearing loss would be included.) In a contributory plan such as this the fact should be exploited that it is a built-in educational device for getting people to use preventive services. Narrow in scope at first, the preventive services could be expanded after further testing and evaluation. Incentives might be given for non-users of alcohol and tobacco, or to communities that take steps toward preventing illnesses.

Quality assessment of health care is discussed from the viewpoint of Professional Standards Review Organizations (PSRO). The evidence concerning the accomplishments of the PSRO's is in the process of being assembled. A reassessment of those PSRO's already in operation suggests that the utilization control programs of hospitals do occasionally report savings, but that improper accounting assumptions were made which resulted in over-

estimations. About their effect on the health of people nothing can be said as yet. In fact, the Office of Management and Budget would like to cancel the PSRO program for being more costly than it is worth. Califano has won a 1 year reprieve for PSRO's to show if they can be effective.

So far as the impact of malpractice suits is concerned, several studies are cited which do not support the notion that there has been an increase in defensive medical practices, nor does there seem to be a major influence on the cost of care. What is recommended is a medical injury compensation system that would effectively promote positive rather than negative defensive practices. For example, arbitration and automatic systems of compensation are proposed. In addition, effective disclosure methods are suggested which will allow patients to participate more fully in decisions affecting their medical care. Attention should be directed to structuring a fair and equitable system for compensation and patient redress. Once the state of our compensation system for medical injury is improved, there will be no question about "defensive medicine".

These and many other medical issues are cogently covered in

Science's special issue. It may contain more than you'll ever want to know about medicine and government, but it is a magnificent one-shot coverage of the present problems.

Why the Professor Can't Teach: Mathematics and the Dilemma of University Education. Morris Kline, St. Martin's Press. \$10.00

If you have ever railed against the injustice of the "Publish or Perish" dictum, this is your book. Is a good researcher necessarily a good teacher? Does a Ph.D. automatically confer on an individual the wisdom and ability to teach? Is researching requisite to communicating a zeal for knowledge and a spirit of inquiry to students? Kline answers a resounding NO to these questions.

The academic landscape is crowded with ruins, according to Kline—student victims of the craving for prestige on the part of university administrations. So long as the game of research is a battle for survival in the academic scheme, teaching will continue to be of low quality.

Senator Proxmire has revealed that research projects are often entirely ludicrous; few produce

anything new and fewer produce anything significant. The result is "a huge proliferation of barely literate papers about pointless subjects". And even if the subject is relevant, it is rarely made accessible to students.

Kline makes a plea to set scholarship and teaching on an equal plane with research. The professional societies should be reoriented to placing a premium on good teaching rather than on published research. The scholarly journals should consider how to encourage pedagogics rather than pedantics.

Somewhere there must be a happy medium. One of our finest teachers in Audiology, Fred Martin, is also a prolific writer.

He has won accolades from the University of Texas for his enthusiastic and effective teaching; he has published several books and many research reports. But he is an exception to the rule. Medical Schools team with learned doctor-researchers who do not communicate their expertise to students.

Were it not for a few dedicated men and women, students in all undergraduate programs would be even more academically stunted than they now are.

MPD

Pick a stimulus, any stimulus

Generate it, Filter it, Phase-shift it, Limit it, Attenuate it, Mix it, Amplify it, Control it, Monitor it ...

Generate it ... Three low distortion, continuous frequency, Wein bridge sinusoid oscillators (less than 1% total harmonic distortion throughout the 100-10,000 Hz range). Variable frequency "buzz" range, offering separate triangle and square wave outputs. White and pink noise generator. Variable gain microphone/line preamplifier for speech and other complex inputs. Variable gain remote microphone amplifier for Intercom Operation.

Filter it ... Three Active Filter Sets, each with independent high, low and band pass outputs. Each filter set provides adjustable frequency cutoff and selectivity controls spanning 100-10,000 Hz.

Phase-shift it ... 0-180° Variable Phase Shifter featuring frequency independence throughout the audio range. Stimulus Phase Reversal Switch and Buffering Amplifier.

Limit it ... Automatic Gain Control featuring adjustable attack and recovery time. Variable Peak Clipper with adjustable clipping level control.

Attenuate it ... Four calibrated step attenuators featuring rotary thumbwheel control and 0 to 69 dB attenuation in 1 and 10 dB steps.

Mix it ... Two mixer-amplifiers, each providing unity or 20 dB gain summing for three input signals.

Amplify it ... Variable gain output amplifiers for: (1) subject's headphones/stereo sound field demonstration speakers, (2) talkback/monitor headphones, (3) bone vibrator.

Control it ... Two programmable electronic gates featuring adjustable rise/fall times. Computer logic Digital Event Programmer provides precise control over temporal sequencing within an experiment. No external logic circuitry required. Two programmer channels control the Electronic Gates. A third programmer channel provides adjustable delay between test trials and conditions, to permit subject responses. A fourth channel allows programmer control over external devices such as warning lights and buzzers. Probability function generator permits control of stimulus delivery schedule for signal

Monitor it ... Input amplifier peak overload indicator for mic/line signals. Switchable peak/average reading VU meter. Phase test circuit monitors waveform relationship at transducers.

Southern Audiologists Meet

The Seventh Annual Convention of the Southern Audiological Society will be held at the Monteleone Hotel in New Orleans from August 30 through September 1, 1978. The program of technical and scientific papers will be on hearing aids. For convention information, please contact-Kay Vernon, Ph.D., Audiology and Speech Pathology, Veterans Administration Hospital, 1601 Perdido Street, New Orleans, Louisiana 70146.

Boys Town Institute Scientific Dedication

The Communication Disorders Institute of BOYS TOWN in Omaha will be dedicated October 4, 5 and 6 at a special scientific conference entitled "Childhood Communication Disorders: Present Status and Future Priorities". Honored guests will be Dr. John E. Bordley and Dr. Thomas L. Smith.

Dr. Patrick Brookhouser, Director of the Institute, has announced a distinguished faculty that includes well-known international participants: Dr.

Ian Taylor of England, Dr. Jan Sekula of Poland, Dr. Gunnar Liden of Sweden, Dr. Paul Fletcher of England and Dr. Harold Evertson of Denmark. In addition some fifty leading clinicians, educators, researchers and health planners from this continent will be featured speakers.

Attendance at the conference is by special invitation only, due to the limited auditorium seating space.

Burchfield Elected To Better Hearing Institute Directorship

James R. Burchfield, Sertoma Foundation president and practicing Columbus attorney, has been elected to the board of the Better Hearing Institute (BHI), a nonprofit educational organization dedicated to informing the hard-of-hearing and others about hearing loss and available hearing help. The announcement was made today by BHI President Ralph Campagna.

"Jim Burchfield was named to the BHI board because of his concern for people with impaired hearing," said Campagna. "As current president of Sertoma Foundation, past president and 23-year member of Sertoma International (an organization that serves the hearing disabled through development of testing and rehabilitation programs), plus 25 years of working with other charitable organizations, Burchfield brings a wealth of experience to his new position. His appointment will add a new dimension to the Institute's board and a new scope and perspective to BHI programs," Campagna added.

Burchfield is active in numerous professional, social, and civic associations. He has practiced law in the near east side of Columbus since his admission to the Bar for the State of Ohio 29 years ago.

Burchfield received his bachelor's degree in humanities in 1947 from Ohio State University and his "doctor of jurisprudence" in 1949 from Ohio State University, College of Law. He and his wife, Dorothy, have three children.

Collette . . .

Continued from page 4

sufficiently to merit vastly increased support from federal or other sources of funding. By 1960 we saw that one of the most opportune things we could do for otolaryngology was to establish a network of temporal bone laboratories that would guarantee a constant input of temporal bones for study. So after 1961 many of the grants were aimed at supporting existing temporal bone banks and developing new ones.

C.O. That was completely successful, as we now know. The concept of donating temporal bones through DRF's national Temporal Bone Banks Programs for Ear Research, became firmly entrenched throughout the country, and a great fund of information began to become available to professionals. For the first time even audiologists became aware of what temporal bone histopathology could tell them about deafness. It is opening up a new world of knowledge in this entire field and has been hailed by authorities as one of the most progressive steps taken in the development of ear research.

Ramsey: It's been a very exciting 20 years for me, and I expect the next 20 will be even more so. All of the efforts must be accelerated if we are to find answers to the basic mysteries of the inner ear and solutions and prevention of nerve deafness and other inner ear disorders.

Editor's Note: In addition to her accomplishments in DRF, Mrs. Ramsey is a noted sportswoman in golf, swimming and skiing. She has held the Baltusrol Golf Club Championship many times and also enjoys skiing, swimming, jogging and yoga.

NEW

The RA226 has capabilities for speech testing (either live or recorded), air and bone conduction testing, subject response monitoring, test signal monitoring, and continuous two-way operator/subject communications. The RA226 is the only audiometer in this price range to include built-in narrow band masking.

NEW

The RA310 Audiometer Calibrator provides an instrument to allow clinics to perform their own calibrations. Performs all standard air conduction audiometer calibrations, simple to operate, rugged carry around case, can be extended in the future.

NEW

The RA208 Compliance Audiometer is a middle ear analyzer and a monitoring audiometer. Simple to operate, push button selection, stimulus offers pure tones or wide band noise, digital displays for compliance & pressure.

The RA206 Clinical Bekesy Audiometer features automatic or manual testing, bone conduction, narrow band masking, six or twelve frequency testing, recording system, and visual presentation.

The RA115A Clinical Audiometer is a two-channel pure tone audiometer. It performs all tests and has narrow band noise & speech circuitry for live or recorded speech. It has push button selection of eleven discrete frequencies & separate interrupter, gain controls & attenuators.

AN INTEGRATED VESTIBULAR LABORATORY

We solved the "shopping problem" by designing a family of components for a complete, attractive and functionally integrated vestibular laboratory of the quality you have come to expect from Tracoustics.

- **ENG Examination Table** extra wide and manually operated, easily adjusted from sitting to fully reclining positions in 15° steps for complete ENG test battery.
- **Single or dual channel ENG Recorder** and bithermal caloric irrigator with timers for automatic operation from tabletop or mounted in the convenient Tracart, as shown.
- **Specialty cabinet** with storage drawers and electrical panel with suction and pressure pumps. Not shown.
- **Digital Light Bar** with calibration lights, optokinetic and pendulum stimuli.
- **Examination chairs or stools** with manual or pneumatic height adjustment.
- **Otoscopes, lights and surgical instruments** available through TRACOUSTICS.

Call us for more details . . .

Sataloff Elected to BHI Board of Directors

Dr. Joseph Sataloff, prominent Philadelphia ear surgeon and noted authority on occupational hearing loss and hearing conservation, has been elected to the Better Hearing Institute board of directors. The announcement was made today by BHI President Ralph Campagna.

A surgeon, college professor, researcher, consultant, and writer, Dr. Sataloff accepted the new position despite his already heavy schedule. "I have a strong commitment to the work you are doing," Sataloff told BHI. "I am delighted to accept and will do everything possible to help."

Besides his private practice, Sataloff is professor of otolaryngology at Jefferson Medical College, visiting professor at the

University of Maine's summer program, and associate editor of the AMA Archives of Otolaryngology. An expert in the area of noise and hearing preservation, he is consultant to the Surgeon General of the Navy in Hearing Conservation, the Secretary of Labor's Noise Committee, the Philadelphia Department of Health, and to many major industries and labor throughout the United States.

In addition to medical school, Sataloff attended the University of Pennsylvania where he received Master and Doctor of Science degrees. He is a member of numerous professional associations, including the American Academy of Otolaryngology and Ophthalmology, the Otosclerosis

Society, the American Council of Otolaryngology, and the American Otologic Society.

Welcoming Sataloff to the board, President Campagna noted the doctor's important contributions in the areas of industrial deafness and hearing loss prevention. "Dr. Sataloff shares BHI's concern for the millions of American workers who are exposed daily to dangerous noise levels," said Campagna. "Author of three books and more than 100 papers on the subject, Sataloff's knowledge and expertise will help BHI expand its anti-noise programs to inform people working in loud environments about the risks involved, methods to prevent loss of hearing, and available help for

those already suffering from damaged hearing," added Campagna.

The Better Hearing Institute is a Washington, D.C.-based nonprofit educational organization dedi-

cated to informing the hearing impaired, their friends and families, and the general public about hearing loss and available hearing help.

AAS ANNUAL MEETING NOVEMBER 17th SIR FRANCES DRAKE HOTEL SAN FRANCISCO, CALIF.

Program:

TIME

7:30-9:50 a.m. Executive Committee
9:00 a.m. Registration Opens
10-12:00 Scientific Papers
12:00-1:00 p.m. Lunch
1:00-2:00 p.m. Carhart Memorial Lectureship
(Dr. Scott Reger)
2:00-2:30 p.m. Wine Break
2:30-4:30 p.m. Scientific Papers
4:30-5:30 p.m. Business Meeting

The Maico Series K. Choice of performance for mild to moderately severe losses.

The Maico Series K is more than just a collection of behind-the-ear hearing aids. It's an articulated concept of hearing aid design that offers excellent flexibility... an integrated system of complementary hearing instruments.

The Series K consists of three basic instruments — K210: ultracardioid performance, K220: non-directional amplification, K230: ultra high frequency emphasis.

To each of these instruments the following options may be added:

- Choice of telephone switch or...
- User operated Response Selector Switch to reduce low frequency background noise or...
- No external switching.

● Choice of three earhooks to suit the individual ear contour.

● Choice of two standard colors in all versions, light or dark skin tone.

● Either CROS or Bi-CROS available.

Once the desired options have been chosen the performance of the aid may be further adapted with two standard controls: a continuously variable low cut control, and a continuously variable output/gain control.

And, unique to the Series K is Maico's exclusively designed, color-coded, easy-to-feel volume control with indexing that shows the amount of rotation at a glance.

The flexibility, performance, and quality of the Series K are worth investigating. For more information on the Series K, write Maico or call our toll free number, (800)328-6366.

CORTI'S ORGAN

The Official House Organ of the American Auditory Society

Vol. 3, No. 4

October, 1978

The Amer. Tinnitus Asso. Lists Prominent Board Members

The American Tinnitus Association was founded in 1973 by Dr. Charles Unice of Downey, California with these goals: (1) to collect information about tinnitus, (2) to disseminate tinnitus information, and (3) to support research in tinnitus. It is this organization that certifies individuals to do the testing and recommend the maskers for tinnitus sufferers.

As Bob Johnson explains in the interview on page 2, there will be a number of training seminars for Tinnitus certification this year. (See page 2 for a complete list). Others will be announced by the ATA later. For information and for membership, write to: The American Tinnitus Association, P.O. Box 5, Portland, Oregon.

The outstanding individuals who serve on the advisory board of the ATA are: Honorable Del Clawson United States House of Representatives, Washington, D.C.; David D. DeWeese, M.D., Chairman, Department of Otolaryngology, University of Oregon Health Sciences Center;

The Honorable Mark O. Hatfield, United States Senate, Washington, D.C.; Robert W. Hocks, National Chairman ATA, Hocks Laboratories, Portland, Oregon; David N. Plant, 2789-25th Street, San Francisco, California 94110, and; Charles Unice, M.D., 10601 Harley Avenue, Downey, California 90241.

Scott Reger

Scott Reger To Give Memorial Lecture

The annual Raymond Carhart Memorial Lectureship has been awarded to Scott Reger of Iowa. To Reger rightfully belongs the title of First Audiologist in the U.S., for he has been an active auditory researcher and clinician since the early 1930's. He knew and was associated with Raymond Carhart in many audiological activities in the three

decades of Carhart's professional life.

In the 1930's numerous articles on audiological research by Reger appeared in the Journals, and much of his unpublished research was reported at meetings. There are hardly any aspects of auditory phenomena that were not originally investigated by Reger, whether formally published or not.

Reger reported in 1943 on screening programs in the public schools. In 1945 he published the classic manual with Newhart on school screening, and was later (1947) involved with Newby in a report on group audiometers in screening programs.

Reger is a member of Phi Beta Kappa, Sigma Xi, the American Otological Society, the Triological, the American Speech and Hearing Association, and is an Honorary Fellow of the American Academy of Otolaryngology.

It is thus a pleasure for AAS to present Dr. Reger to a generation of audiologists who may not have fully appreciated his immense influence on the field. It will be a real privilege to hear one of the truly Greats of Audiology.

His lecture will begin at 1:00 p.m. November 17 at the Sir Francis Drake Hotel. (See program on page 9).

Bells Are Ringing For Jack Vernon

Many people have been actively involved in the Tinnitus project at Kresge Research Labs in Portland, and an entire national association is focussing its sights on the topic. But it was one man who had the initial vision and the dogged determination to develop this program that would help thousands of sufferers from tinnitus. Modest almost to a fault, Jack Vernon talks about "luck" and "serendipity" as responsible for the success of his program. But those who know say that this most compassionate of men was driven simply by the thought of the possibility of alleviating the distressing symptom of tinnitus that has been rightly termed "maddening".

So it is appropriate that Corti's Organ explore the development of the Vernon approach to tinnitus, and in the process reveal more about this scientist and gentle man. Our interview with him follows:

Q.: How did you first become interested in the problem of tinnitus?

A.: The whole thing started because Kresge Hearing Research Lab is a division of the Department of Otolaryngology and is clinically oriented. We do try to do clinically relevant studies and we felt that we had really bypassed the most common entity that is seen in the practice of otolaryngology, namely, that of tinnitus, long enough and that we should indeed go to work on it. We started out to see if we could develop an animal model that would tell us when the animal had tinnitus so that we would have the proper basis to work with. And that actually, believe it or not, went very well. We had a grant that had been approved and would be funded by NIH, when Mr. Nixon put a moratorium on NIH funds and in that moratorium we lost our lab, we lost our animals, we lost a lot of things. We had Rhesus monkeys trained to make discriminations when there was a tinnitus-like sound present, and when we got them to the point of their discrimination at a 90% correct level, we then switched them over and injected them with sodium salicylate, getting blood levels that were sufficient to produce tinnitus in man. Half the animals had saline and half had sodium salicylate and we didn't know who was who. It turned out that when you tested these

Jack Vernon at Vail.

animals, the animals who had the sodium salicylate indicated that they heard something every time they were presented with the choice, suggesting to us that they indeed had tinnitus. The other group of animals who had saline, half the time they said they heard something and half the time they said they did not. So the data were not quite as crisp as you would have liked. But it was certainly encouraging enough to go on. It was with those data and at that point that we applied for a research grant to study tinnitus in animal models. It was approved and it was to be funded and that's when Mr. Nixon stepped in with the moratorium, so we lost the whole thing. That did a very interesting thing. That put us on the record at NIH as the one laboratory in the country at the time that was studying tinnitus. And we began to get many letters from people around the country. Interestingly enough one of these letters came from this Dr. Charles Unice, who is the founder of the American Tinnitus Association.

Q.: Yes, I understand that Dr. Unice had intractable tinnitus, and heard about what you were doing. What happened?

A.: He came up here and we began testing him without the faintest idea of what we were

AAS Annual Meeting Starts Early On Nov. 17

An unusually large number of submittals of papers at this year's annual meeting has necessitated an earlier start than usual for the program. It will begin at 10:00 a.m. in Sir Francis Drake Hotel.

A large crowd is expected to hear Scott Reger's lecture as well as the large number of excellent reports that will be made. The complete program can be found on page 9.

Editorial...

Now he's got us doing it — saying "tin-night-iss" instead of "tin-it-iss" (we don't trust our printers with diacritical marks). Yes, Jack Vernon has changed a generation of us who were addicted to the old pronunciation of tinnitus. He's been insisting for years that there is only one way to pronounce it, and finally we too capitulated — even before we saw that the latest Webster's lists only "tin-night-iss" as acceptable! So get on the Vernon bandwagon everybody — it's here to stay.

We have a few gripes of our own — for example, we tear our hair and scream whenever anyone says "larnyx" for "larynx". And we fall on the floor and beat our hands when we hear "nucular" for "nuclear". Further tantrums are produced by having the Weber test pronounced "Weber" instead of "Vay-ber", and the Rinne test called "Rinnay" instead of the German "Rinn-uh". But if you want to see us completely disintegrate into little pieces, just try saying "This data is...". Just the thought of it has already spoiled our day. MPD-RJR

The New Tinnitus Team Member . . . Bob Johnson

Since June there has been new activity in the tinnitus Clinic at Kresge Labs in Portland. Bob Johnson is a big man physically, mentally and professionally, and his presence would stir things up on any staff. With his coming the group is launching a large-scale training program that will extend the skills and knowledge of the Kresge group to any professionals who are interested.

In an interview with *Corti's Organ*, Bob explains the directions of the new program and how one can get involved in a tinnitus program.

Q: Tell us how you happened to get interested in the tinnitus work and how you became a part of the team.

A: I always have been interested in the area of tinnitus. However, I didn't actually get involved in it until Jack decided that he should have an audiologist aboard to help him with the tinnitus program, which had expanded considerably

from what it had been in the first couple of years. He called last December and asked me if I would be interested in making a change and joining him up in the Portland area to become involved in this kind of a program. So after flying to Portland and looking at the program I decided to devote at least the next few years in working with the tinnitus program with Jack. It has certainly turned out to be a good professional change on my part. Right now we

Vernon & Johnson try out the masker

are involved in a tinnitus clinic in which Jack and I share the responsibility. Up to this stage we have not only had a clinic for the tinnitus patient but as you know we have also had a training program which meant bringing in anywhere from 4-10 observers a day. These observers were generally either otolaryngologists, audiologists or hearing aid dispensers. The program up to this point has been one in which the person observes what is going on in the clinic — an informal type of a program where much of the time was spent answering questions of the observers and trying to supply information. Both Jack and I have felt that this distracted both from the observer program and from the clinical program, in that what we were trying to do is to give time to both elements and actually probably not spending as much time as we

Random Thoughts On Hearing Aid Fitting (While Shaving)

Kenneth W. Berger
Speech and Hearing Clinic,
Kent State University

Most of the world's religions and numerous other groups have found value in meditation. Meditation provides a means of reflecting on past events and of letting one's thoughts wander through possible future actions, while briefly blotting out the din of the workaday world. My non-theological meditation period is each morning, while shaving with an ancient three-headed electric razor. Without casting aspersions on the products of Messrs. Grason and Stadler, this old razor masks environmental sounds more efficiently than their costly model 1701 audiometer.

In addition to masking by the razor, the time spent shaving is an excellent period for meditation inasmuch as it requires minimal concentration to the task at hand, that chore having been repeated so often as to become automatic. By now I've shaved 13,870 times (based on 365 days per year times 38 years) give or take a few, since a stubbled chin was acceptable while camping out, but on a few special occasions, especially in my younger days, an extra shave in the evening was deemed advantageous. At any rate, a number of random thoughts about hearing aid fitting have rambled through my mind while shaving and a few of these, for whatever their worth, are shared with the reader.

What A Hearing Aid Is Not

A typical textbook definition of a hearing aid is something to the effect that it is a wearable electronic amplifier, specifically designed for assisting those with impaired hearing. That definition may be correct, but it does not indicate how the assistance is accomplished. One might falsely assume, for example, that the hearing aid is curative or alters the wearer's auditory mechanism in some manner. A more complete definition of a hearing aid would also mention that it responds to incoming acoustic signals, modifies them, and conveys them to the ear. The modification and efficient delivery of those signals will, ideally, enable the wearer to better use them. The main point is that the hearing aid doesn't change or replace any part of the auditory mechanism of the wearer; it merely delivers the modified acoustic signal to the ear.

If one accepts the preceding statement it seems to follow that the hearing aid is not a prosthesis. A plastic or metal strut can be used to replace a diseased stapes and, therefore, is a prosthesis. An obturator may be used in the case of a cleft palate, and is a prosthetic device. However, the hearing aid meets neither the dictionary nor the medical definition of a prosthesis. To consider the hearing aid a prosthetic device only confuses the issue and can impede the progress of scientific hearing aid fitting.

The Federal Food and Drug Administration has recently ruled that the hearing aid is a medical device. Thus, legally the hearing aid is now so classified, by regulation rather than by legislation.

The reasons for the F.D.A. classifying the hearing aid as such seem obvious and I have little quarrel with their motive. However, except for narrow legal purposes the hearing aid is not a medical device. Rather, the hearing aid is an option (a) when medicine or surgery cannot correct the hearing problem, or (b) when the individual chooses not to have medical or surgical treatment that might correct the problem. Only after medical and surgical treatment have been dismissed as alternatives should a hearing aid be considered.

An analogy on this point may be worthwhile. Analogies are often of assistance in argumentation, to confirm one's biases, perhaps because analogies are seldom totally analogous and also since they are so abundant that one may be found to be approximately appropriate to any argument. Consider the balding middle aged male. (On that subject I am an acknowledged expert). He can seek the advice of a skin specialist regarding medication or even surgery to alleviate his problem. Should the dermatologist conclude that medical treatment and surgery are inappropriate the individual might consider purchasing a toupee. The toupee would seem to be no more of a "medical device" than a hearing aid despite its more nearly meeting the definition of a prosthesis than a hearing aid.

One day while trying to make certain my graying sideburns were of equal length I began meditating about medical devices. In the process of shortening the right side I recalled some writers referring to the pure tone audiometer as a "medical audiometer". The purpose of this distinction, evidently, is to sully the audiometer name as inappropriate outside medical use. The pure tone audiometer, now commonly calibrated to ANSI (1969) standard, of course, is used within the broad medical diagnosis of hearing disorders. In addition to diagnostic value, medical as well as non-medical, results obtained with it may be used for purposes of prognosis, prediction, confirmation, and comparison, by unaided and by aided measurements. One might even venture to use the "medical" audiometer to produce simple melodies. For example, with it one can approximate the first five tones of the **Star Spangled Banner**. Such would be facetious, but the possibility of seeing this non-medical use of the audiometer on the Gong Show is frighteningly real.

Consider the tuning fork. This was invented in 1711 by John Shore to Assist musicians in tuning their hautboys and zithers. (Remember the name John Shore and 1711 so as to impress your friends the next time the topic of conversation turns to trivia). It is still used by musicians for the same purpose. A century later otolaryngologists found the tuning fork useful for testing hearing. Now, are otolaryngologists using a "musical device"? If Carlo Ponti spins his spaghetti on the spoon with a tuning fork should he be required to join the musician's union or be sued for practicing medicine without a

license? The point, now well beyond 20% distortion, is that to call the pure tone audiometer a "medical" audiometer is to capriciously restrict, in advance, the usage to which it is put.

Hearing Level and Sound Pressure Level

Meditating about the audiometer leads rather directly to hearing level (HL) and sound pressure level (SPL). The measurement and charting of auditory behavior may be on the basis of either, and each has its advantages as well as disadvantages. Wernicke's area can't differentiate HL from SPL, so the choice between the two is really that of the operator of the test device and those who will use the resulting data. Let's consider another analogy. Suppose on a frigid winter morn you go outside and note that one thermometer reads -32° Fahrenheit, and another thermometer reads 0° Centigrade (or Celsius). Regardless of the thermometer you are no colder, or warmer, by using one than the other, unless you choose to be the victim of your own conditioning to numbers. It may be noted that converting dB SPL to dB HL, or vice versa, is considerably more simple than the translation from Fahrenheit to Centigrade, although there is a different conversion factor for each frequency. It would also appear to be purely personal preference whether one wants good hearing to be at the north end of the chart and poor hearing at the south, or the reverse, or even change the chart to read horizontally or diagonally.

Beep Beep, Sh Sh,
or Clunk Clunk

In measuring human hearing and the effect of amplification, the chosen test signal needs careful consideration, and its characteristics clearly understood. Numerous test signals are available to the clinician. The most commonly used test signals are undoubtedly pure tones. A bounteous research and clinical literature has been published involving pure tones. In determining the usefulness of a hearing aid to a given hearing loss, and especially in testing the results of amplification, the use of pure tone stimuli is often harshly criticized. The criticisms are usually twofold: a continuous pure tone signal is likely to set up standing waves in anything less than an anechoic chamber, and the level will vary substantially within the test room.

Surely we should not expect a junior in Speech Pathology and Audiology (much less someone with a coveted ASHA certificate in audiology) to employ a continuous pure tone in free field clinical testing. Continuous pure tone signals may well set up standing waves, and their level does seem to vary more than some other signals within a test area. The latter is a minor problem inasmuch as the signal should have been calibrated to one particular location in the test room, and we will warn the client not to walk, waltz, or wander aimlessly around the room during testing.

Pulsed tones are considerably more trustworthy than

continuous pure tones for free field testing. However, unless the test room is well sound treated standing waves may still be set up. That is, theoretically an outgoing pulse may be met precisely in phase with sound reflected from a hard surface, in which case the intensity of the combination will be 6 dB greater than the original. If the outgoing pulse is met precisely out of phase with a reflected sound (assuming no absorption) in combination should cancel each other, resulting in no sound, although in fact neither condition can be realistically achieved. Interactions other than perfectly in phase or perfectly out of phase result either in less than 6 dB increase or a reduction to less than total silence. More worrisome than standing waves is that the client must be advised to not move the head during testing, otherwise test data are invalid. A rigid client head position during free field testing, except perhaps in localization research, seems to be important regardless of the test signal.

Warbled tones are slightly more acceptable in audiology circles than pulsed tones for free field testing. Journal editors and thesis committees seem more satisfied when warbled tones are used even though they may produce momentary standing waves at a frequency where the pulsed tone would not.

White noise is a rather good signal for free field testing. Its use is sometimes criticized in that as one looks at this stimulus on an oscilloscope there are random blotches. Since white noise is, by definition, random, this picture is not unexpected. Whether the human ear can detect the occasional blotch seen high or low on the oscilloscope is problematic, and we don't fit hearing aids to oscilloscopes. The main disadvantage to its use is that, like music or speech, white noise obscures frequency information.

Narrow band noise appears to meet most of the requirements of a signal for free field test purposes. Its major disadvantage is that if there is a large precipitous drop between two test frequencies the filter skirt may not permit accurate testing. This problem is virtually overcome if narrow band noise is used for both unaided and aided testing. It has been argued that narrow band noise rapidly fluctuates several decibels, plus and minus. This is true, but presents no real difficulty, because the ear will respond to the highest variation of the noise, and one can readily calibrate the dial to that level.

A damped sine wave has been reported to be useful in hearing aid fitting, although it presents the same problem as narrow band noise in the case of a precipitous configuration. (Note how cleverly the latest "in" word in audiology was sneaked in at the end of that sentence). More competent writers often use the word configuration twice in the same sentence. At present only one manufacturer is known to make available an instrument to emit assorted damped wave train signals, but such signals can be produced in the laboratory with appropriate apparatus. Further-

more, one might then tape record the stimuli and play them back through existing audiometric equipment should the cost of a damped wave train apparatus be prohibitive to a given budget.

To date only the most rudimentary psychophysical data have been published on the damped wave train. Presumably this type of signal permits more reliable testing than pure tones in rooms with minimal sound treatment. One might speculate that the damped wave train will be found to have diagnostic value in comparison with pure tone signals. We need to keep an open mind to the possibility that damped wave trains, or modulated complex tones, or some other signal may be more appropriate for aided testing than pulsed pure tones, warbled pure tones, or narrow band noise.

Hearing Aid Evaluation

The traditional hearing aid evaluation, modified, mangled, and maligned over many years, has served its purpose historically. But, it has outlived its usefulness. At its worst the hearing aid comparison procedure probably permitted the clinician to discard the least effective of the pre-selected hearing aids. In retrospect, however, hearing aid comparison procedures undoubtedly retarded the scientific fitting of hearing aids inasmuch as the results of comparisons are for the most part unresponsive to anything less than major changes in electroacoustic characteristics, earmold modifications, tone control changes, tubing alterations, and filters of various sorts. The memory of the late Raymond Carhart, the Father of Audiology, is not enhanced by continued use of a time consuming procedure that has been shown to have inadequate reliability and validity.

At this point in time, those involved with hearing aids need to clearly describe their goals in fitting. The more vague and subjective the goal the more likely it will be achieved but without recognizing how or why. The more specific the goal the more one is open to sniping criticisms. The goal, and the method of reaching it, should be based upon the best available research evidence. Where research data are unavailable we can fall back on clinical experience and logic, and if none of these are readily available or apparent on a particular point we may use arbitrary numbers. Even arbitrary factors have the value that they provide something specific against which to test, compare, and alter.

We are overdue in setting up specific procedures and testable hypotheses for hearing aid fitting, rather than groping through another two decades of "fit and try". In broad outline the procedures would include: (1) a clearcut determination of hearing aid candidacy, (2) choosing a test signal considered most valid and reliable for the purpose intended, (3) deciding on the precise goals of the fitting, (4) specifying generically the electroacoustic factors which might best achieve

Briefly, Books

PEDIATRIC AUDIOLOGY, Ed. Frederick N. Martin, Prentice-Hall, Inc., Englewood Cliffs, N.J., 1978.

The reader will find this text's chapters highly organized in their presentation of material. Previous research is reviewed objectively and new areas of diagnosis are presented theoretically and practically. A comprehensive discussion of development in the infant and the child is well done. **Pediatric Audiology** talks about management of the child in the medical office as well as in the public school setting.

Professionals working with this population, whether in diagnosis or habilitation will find **Pediatric Audiology** a most useful text.

Lynne R. Anderson

AUDIOLOGICAL ASSESSMENT Ed. Darrell E. Rose, Prentice-Hall, Inc., Englewood Cliffs, N.J., 1978.

Audiological Assessment is updated and indispensable to the student of audiology. "Otolologic Assessment and Treatment" is a much needed chapter especially to clinicians not familiar with ENT procedures. Illustrations throughout the book are extremely well done. Current advances in evaluation are presented but based upon the foundation of an understanding of sound anatomy and physiology of the ear, and basic pure-tone testing techniques. The new HAIC standards for hearing aids are discussed at length.

Although some topics are mentioned only briefly, a well-referenced bibliography completes each chapter. **Audiological Assessment** is an in-depth reference text.

Lynne R. Anderson

American Council of Otolaryngology's "Job Information Exchange Service" adds audiologists

The American Council of Otolaryngology's "Job Information Exchange Service" is now accepting listings from audiologists who are seeking employment. This service, which has been coordinated by the ACO for the past six years, was previously limited to otolaryngologists plus physician assistants and military technicians in otolaryngology.

Because otolaryngologists frequently hire audiologists for their private practice, hospital and university staffs, the new category for audiologists was added as a service for the ACO membership.

The "Job Information Exchange Service" provides an exchange of employment information for the specialty. The ACO publishes job listings quarterly and sends this information to its membership of nearly 4,000 otolaryngologists throughout the U.S. Listings are kept current and are available upon request between editions. Audiologists interested in participating should contact Job Information Exchange Service, The American Council of Otolaryngology, 1100-17th Street, N.W., Suite 602, Washington, D.C. 20036, or call (202) 659-4591.

Noise Control

The 1979 National Conference on Noise Control Engineering will be held at Purdue University, West Lafayette, Indiana USA on April 30 to May 2, 1979.

The conference is sponsored by the Institute of Noise Control Engineering/USA and the R. W. Herrick Laboratories, Purdue University. The conference is organized by the R. W. Herrick Laboratories. The General Chairman is Professor Malcolm J. Crocker and the Program Chairman is Professor J. W. Sullivan.

The theme of NOISE-CON 79 is Machinery Noise Control. Several different sessions will be held in which both invited and contributed papers will be presented. The sessions will include but not be limited to papers on industrial machinery, engines, pumps, compressors, home appliances, and components on vehicles (mufflers, fans, etc.). Not included within the scope of the conference will be aircraft noise, noise from complete vehicles and community noise. Suggestions on special sessions are welcomed.

Contributed papers: Each session in the Conference will consist of invited and a limited number of contributed papers. Contributed papers will be selected by review of long abstracts (maximum 1000 words and up to one figure and 5 equations if needed). The deadline for receipt of these abstracts is December 15, 1978.

Prior to NOISE-CON 79 on April 26-28, 1979 there will be a special seminar on machinery noise control.

For more information on the conference or seminar, please write:

NOISE-CON 79
116 Stewart Center
Purdue University
West Lafayette, Indiana 47907
Telephone: (317) 749-2533

Abstracts should be mailed as soon as possible to:

Professor J. W. Sullivan
Program Chairman
Ray W. Herrick Laboratories
Purdue University
W. Lafayette, Indiana 47907
Telephone: (317) 749-6345

Professor Sullivan can also send further information on submission of abstracts if required.

Murphy's Law

#5

There is nothing sadder than a great idea whose time has not come!

Noise Control Engineering Begins 6th Year of Publication

NOISE CONTROL ENGINEERING, the technical journal of the Institute of Noise Control Engineering (INCE) has, with Volume 11, entered its sixth year of publication.

The bimonthly journal, edited by Professor Malcolm J. Crocker of Purdue University, is the only magazine published in the United States which prints refereed articles concerned exclusively with noise control.

Bells Are Ringing . . .

Continued from page 1

doing. I can remember hammering on him, beating on him, doing all kinds of things for one whole morning and as I look back on it now I just shudder. Then we took him out to lunch and we brown-bagged it, sitting there by a fountain. Suddenly he got up and walked away from us. After a while I got up and asked if he was alright and he said shh, shh, shh, I can't hear my tinnitus because of the waterfall of this fountain. And that is when the whole idea of masking fell into place. We couldn't put Chuck by the waterfall for the rest of his life but we could put waterfalls in his ears, and so that was the beginning of the tinnitus program.

Q.: You said that at first you had the wrong idea about what masking would do.

A.: I sure did, I thought masking with tinnitus would be like any other masking, but it isn't. Indeed, all of the rules and the laws, going back to early work, just did not apply in the case of tinnitus. For example, if one has a band of noise, a physical band of noise, and you try to cover that up with a pure tone or mask it out with a pure tone, you're going to have a terrible time doing it. It takes an enormous amount of intensity. In the case of noise-type tinnitus it is very easily covered by the pure tone, provided of course, you select the proper pure tone. You can also do it in reverse. So there are many ways in which tinnitus does not obey the laws of masking at all and the most telling one to me was that I thought: if one had tinnitus and you introduce a second sound, that those two sounds would seek a common level that was about half way below the tinnitus and the patient would wind up listening to two sounds, but at much less intense levels than the tinnitus alone. Somewhere I've actually got that statement in print. Well, that is not at all true, that's not what happens at all. Indeed one has to go all the way up to the top of the tinnitus to cover it up. So you are substituting another type of sound for the tinnitus, rather than doing anything that is like a true masking. Masking is really a bad word and I'm apologetic for having put it into the literature, but I think it's too late to try to change it now. Professor Feldmann in Munich called it "inhibition" and indeed we coined the term "residual inhibition" in honor of his work.

Q.: You have really introduced a

new concept and a new phenomenon in the "residual inhibition" idea. How do you define it?

A.: Residual inhibition is a continuation of the masking effect once the masking sound has been removed, and that turns out to be one of the most exciting things that's ongoing with our program right now. It occurs when you properly mask the tinnitus. Let us just take an example. Suppose somebody has tinnitus at a relatively pure tone of 3500 Hz. If one takes a 3500 Hz tone or a mellow band of noise centered at 3500 Hz and masks the tinnitus out for one minute and then takes away the masking sound, the tinnitus will usually be gone, and indeed would be gone in 78% of our patients, for about 30 or 40 seconds after that and gradually would return. And that absence of tinnitus after masking is what we call residual inhibition.

Q.: Is it a linear effect if you mask for 2 minutes and get a corresponding period of inhibition?

A.: That's a very important comment that one must make to patients. If you make the demonstration to patients the automatic thing that pops in their mind is "what if I mask all day long?" No it is not linear. We don't know the laws of residual inhibition and we're studying it to determine those now. There is some tendency for the period of residual inhibition to increase as you increase the length and the intensity of the masking experience. However, I don't think that that is the key. For example, we have five, six or may as many as a dozen patients who are getting very long periods of residual inhibition. For example, there is a lady here in town who puts on her maskers at 8:00 in the morning and wears them until 10:00 and then she is free of tinnitus, totally free of tinnitus until 4:00 in the afternoon. Then she puts the maskers back on and wears them until she goes to bed. We have a patient in Spokane, Washington who gets up and masks while he is shaving, dressing and going to work—maybe a total of an hour—then he has twelve solid hours of no tinnitus. He has had a twenty year history of tinnitus. Some of these people are asymptomatic for very long periods. But one has to say to the patient, please don't expect that as part of your relief program. The only relief that you really should count on and expect is that which you experience during the masking itself.

Q.: You have identified 5 different

types of effective masking protocols, is that true?

A.: We started out with only 1, and remember I was at least 180 degrees off course on this thing. I thought that all we needed to do was get a band of noise into the ear and really the only requirement is that it not go down very far into the speech frequencies because you don't want to tear up speech for the patient. They've got enough trouble without that. So we have a behind-the-ear unit that would start no lower than 2000 Hz and then go on up from there. That may sound like a bad choice but it turns out that a very high percentage of tinnitus is above 2000. Indeed, I think in our sample of 513 patients, 78% of them are above 2000 Hz, and that majority has tonal tinnitus rather than noise. So it seemed to make sense to do it that way. However, we very quickly ran into a situation where the original wide-band masker going about 2000 or 1800 Hz to 5000 Hz, simply did not cover a lot of people, mainly those who were above 5000 Hz. Then we started emphasizing to the industry that we needed maskers that go higher. They did find a new transducer, that was being produced in Holland, rather than the one that is typically produced by Knowles' here in Chicago. And the new transducer would go very easily to 7000 and occasionally you would find it going beyond that. So they developed for us what we call the high frequency masker, running from about 2000 to about 700 Hz. We have continued to emphasize the need for high frequency and very recently Audiotone started producing a high frequency masker that we ought to

those goals, (e) testing the client with the hearing aid to confirm how well the goals were reached, (f) accomplishing items a through e in as little client time as possible, with as few client return appointments as possible, and with as little investment in apparatus and instruments as possible, yet without sacrificing accuracy, and (g) being open and amenable to modifications in our fitting procedures as new evidence and new technology become available.

Now for a dash of after shave lotion, and off to the workaday world.

Continued from page 5

call super high or something. It starts around 2000 and some of them go up to 14,000, some of them to 10,000, some of them to 12,000 and indeed about three or four weeks ago we covered up a young patient who had tinnitus at 15,000 Hz. That's one of the highest we've ever seen and yet we could successfully cover up his tinnitus: he is now going back to school, after quitting, and is now in Law School to complete his professional career. In addition to those three maskers, there is a low frequency masker that starts at about 1000 Hz and goes downward. We don't see much low frequency tinnitus because we ask that only severe cases be referred here. I think that low frequency tinnitus tends not to be a severe form. Usually if anybody has residual hearing left over it's usually in the low frequencies and there is plenty of low frequency ambient noise around, so that low frequency tinnitus tends to get

masked out pretty much as a normal consequence. But we do see it. Out of our 513 patients, I think we've seen 11 or 12 that have tinnitus below 1000 Hz. The fourth one is a combination unit, a combination of a hearing aid and a masker. That unit was really invented for us by one of our patients, who literally picked up a masker and a hearing aid, put them together with rubber bands and a y-tube, and stuck the thing behind his ear. His ear stuck out about 90 degrees to his head, but he got his tinnitus on that side under control. Then when this combination instrument was developed as a consequence of that, he among others is wearing what amounts to be 4 units.

Q.: What are the output levels of these aids?

A.: The top level of all the maskers has been 85 dB, the bottom level is about 40 dB. There are

some people whose hearing is so depressed that you can't get to them with 85 dB. We have one experimental model that is a power unit that puts out 112 dB. We have not had much success with that with patients who are really hard of hearing, by plugging the ear canal and putting a lot of energy in there. Harry Zimmerman at Las Cruces, New Mexico really invented this procedure, occluding the ear and then putting the tube through the occluding mold to get a lot of energy into the ear. He has been successful with some patients and so copying his lead we tried to do the same thing here. One particular patient we have been working with over three years. We still have not been able to relieve her. She's one of those tragic post-stapedectomy cases that had a viral infection in the ear.

Q.: What's the average intensity level of the tinnitus that you've measured?

A.: The sensation level is about 5-10 dB, not as loud as I thought it would be. I had thought that severe tinnitus would be very loud, but that's not true. Even severe tinnitus is usually no more than 5-10 dB. The loudest I've seen was a patient with around 50 dB, but that is most unusual. It is very interesting when you have properly identified the pitch and then you pick that frequency and come up with that sound, at the point where the patient hears it, it nearly masks it out. That's really what you'd like to have.

Q.: What's in the future?

A.: I think that you can see that the next generation of maskers is going to be a prescription affair. For example, visualize an audiogram where the patient has no hearing loss out to 2000 Hz, then at 3000 Hz they're down to 60 dB. And then their tinnitus is stuck out there at 4000 Hz. Then you broadcast a band of noise from 2000 to say 5000. In order to get enough intensity to cover up the tinnitus where the hearing is bad, there's so much intensity where their hearing is good that they really can't tolerate the masker. You see we are defeating the masking purpose by flooding them in their clear area. Therefore, what one wants, as I see the next generation of maskers, will be one that has a very steep skirt on it, steep skirts on both side, and a very narrow band, maybe only 5 or 10% band, that is centered right on top of the tinnitus and then I'll bet you'll be able to run the gain at sensation level of 5 or 10 dB and you won't put anything down in the clear area. That would just be the way to go. We've got a study going right now that asks what kind of sensation levels you need at

various frequencies. If you take the frequency that's right on the tinnitus it only requires 5 dB or maybe even less sensation level. As you use frequencies below that the necessary levels get higher and higher and higher. And indeed, you might be using as much as 60 or 70 dB. It's another one of those cases that's just the reverse of what the usual masking situation is like. By the way Wegel had tinnitus. He wrote a fascinating article on tinnitus where he matched his and then he was able to produce beats with it. Indeed, we saw three patients in whom we could produce beats with an external sound against their tinnitus. Davis and his group were studying acoustic overload during the war and they commented that their tinnitus and the fact that they could not produce beats the way Wegel had and so discredited his findings. It is just a rare phenomenon, but it can be done.

Q.: Why do these particular people who come to you have such great problems with their tinnitus when it's usually quite a low sensation level?

A.: Well, I think severe tinnitus is the third worse thing that can happen to you. I think severe retractable pain is the worst thing. It's interesting that two anesthesiologists from New Zealand named Good and Melding were working in a retractable pain clinic. One of the things they decided to do was use massive doses of IV lidocaine, a topical anesthetic and they were indeed controlling intractable pain for a lot of people. One particular day they had a man in with low back pain for which nothing could be done and they gave him the injection and asked him how is your back pain and he said "just the same—it didn't help it at all—but you did take away my tinnitus." So that got them thinking about that possibility and they indeed started treating tinnitus patients. And they found with medication the tinnitus would temporarily go away. They also started giving Tegretol to these people and they found that those that had responded positively to lidocaine also positively responded to the Tegretol. There was only one thing wrong with the tegretol—one runs the danger of aplastic anemia. So Tegretol is no solution. But other drugs may be

CLINICAL APPLICATION OF AUDITORY EVOKED POTENTIALS

November 8, 9, and 10, 1978

The Division of Audiology and Speech Pathology, Department of Otolaryngology and Maxillofacial Surgery of the University of Cincinnati Medical Center will sponsor a conference entitled "Clinical Application of Auditory Evoked potentials" on November 8, 9, and 10, 1978. Featured speakers will include two authorities on this subject, A.R.D. Thornton from Southampton, England, and Claus Elberling from Copenhagen, Denmark. Topics under discussion will include both audiological and neurologic application of brain stem responses. This will be primarily a didactic course, although practical demonstration of several commercially available evoked response systems, as well as training in electrode techniques, will be available.

Tuition for the course, to be held at Stouffer's Inn in Cincinnati, will be \$100, \$125 for physicians, and \$60 for students. Inquiries should be directed to:

1979 EAR SURGERY COURSE

JANUARY 28, 1979

TAMPA, FLA.

Dr. Harold F. Schuknecht, T. Manford McGee, J. Brown Farrior and Mansfield F. W. Smith will give a course in EAR SURGERY in Tampa, Florida at the Holiday Inn Central (\$24-\$30) on Sunday, Monday, Tuesday, Wednesday & Thursday AM, January 28-February 1, 1979.

This is an intensive four day course covering Myringoplasty, Tympanoplasty, Mastoidectomy and Stapedectomy.

29-9 CME Credit Hours.

For details write to: Southern Foundation, OBH, c/o J. Brown Farrior, M.D., 509 Bay Street, Tampa, Florida, 33606.

The Maico Series K. Choice of performance for mild to moderately severe losses.

The Maico Series K is more than just a collection of behind-the-ear hearing aids. It's an articulated concept of hearing aid design that offers excellent flexibility... an integrated system of complementary hearing instruments.

The Series K consists of three basic instruments — K210: ultracardiod performance, K220: non-directional amplification, K230: ultra high frequency emphasis.

To each of these instruments the following options may be added:

- Choice of telephone switch or...
- User operated Response Selector
- Switch to reduce low frequency background noise or...
- No external switching.

• Choice of three earhooks to suit the individual ear contour.

• Choice of two standard colors in all versions, light or dark skin tone.

• Either CROS or Bi-CROS available.

Once the desired options have been chosen the performance of the aid may be further adapted with two standard controls: a continuously variable low cut control, and a continuously variable output/gain control.

And, unique to the Series K is Maico's exclusively designed, color-coded, easy-to-feel volume control with indexing that shows the amount of rotation at a glance.

The flexibility, performance, and quality of the Series K are worth investigating. For more information on the Series K, write Maico or call our toll free number, (800)328-6366.

Book Reviews

Yanick, Jr., Paul and Freifeld, Stephen F., Editors. **The Application of Signal Processing Concepts to Hearing Aids.** New York: Grune & Stratton, (1978), 240 pp. Reviewed by Hal Weber, Director, Speech & Hearing Services, Colorado Department of Health Denver, Colorado

This book consists of a collection of essays representing some of the proceedings of the First Symposium on the Application of Signal Processing Concepts to Hearing Aids, sponsored by the HEAR Foundation in September 1977.

The scope of the subjects addressed in the 14 chapters include: distortion found in the cochlear damaged ear; auditory perception in the normal ear and effects of noise on speech communication; critical review of current hearing aids; electroacoustical dimensions of hearing aids and current measurement practice; review of the Master Hearing Aid, including current available models, advantages and practical limitations of each, and guidelines for the design of the "Ideal" Master Hearing Aid and/or Universal Hearing Aid; review of signal processing techniques for the hearing impaired person. (Signal processing is defined by one contributor as the process of transforming the signal parameters so that to the hearing impaired the signal received at the cochlea is the same as an unprocessed signal would be to the normal listener). Application of existing technology for promising new signal processing approaches are presented such as multi-channel compression circuitry for the patient with greater cochlear recruitment in the high frequency range of the hearing aid then for the lows; the design and use of micro computer hearing aids; and, although it would seem to have limited clinical value at this time, the development of a mathematical model which accurately predicts the sound spectrum developed at the tympanic membrane in both real and artificial ears.

The final three chapters address the special problems in audiological assessment and medical diagnosis and treatment of the patient with cochlear hydrops. The discussion is apparently presented to caution clinicians against misinterpreting symptoms such as fluctuating hearing sensitivity and reported "fullness in ears" to be otitis media. However interesting, this discussion seems somewhat out of place with the remaining chapters.

Since the chapters were originally independent presentations at the symposium, it is understandable that some common concepts and topics are discussed by several contributors. Three of the chapters are revisions of oral presentations which were given extemporaneously from notes. In these chapters, the authors were afforded the opportunity to make direct references to statements made by previous speakers. This reader found the discussions of common topics by several contributors to be refreshing, informative and broadening of understanding of the issues rather

than viewing these discussions as simple redundancy.

The expressed intent of the book is "to provide useful information to members of the hearing health care team concerned with the improvement of rehabilitation procedures in the area of sensorineural deafness". It proposes "to set forth important observations while emphasizing practical new ideas that are available to provide compensatory signal processing for persons with sensorineural hearing loss".

The intent has been fulfilled.

Alpiner, J.G. **Handbook of Rehabilitative Audiology.** Baltimore: Williams & Wilkins, (1978), 267 pp.

Reviewed by:

Janet M. Zarnoch

This book represents the most comprehensive handbook of adult rehabilitative audiology. Alpiner has done an excellent job of combining his wealth of knowledge on the subject with his unique ability to provide useful, practical clinical information for the practicing audiologist. In addition, five other contributors have provided their insight and expertise in the area of adult rehabilitative audiology. Chapter 11, the final chapter very appropriately deals with the direction of future research in this area of rehabilitation.

Alpiner provides the reader with a concise, yet very complete view of literature, as well as state-of-the-art. Perhaps one of the most valuable aspects of this text is the reproduction and explanation of various diagnostic tests currently available to assess communication function in the adult hearing impaired population. Of particular note is the attention paid to a special population of hearing-impaired adults, namely the geriatric. Alpiner generates considerable discussion on this special group and also presents a scale of communication designed specifically for use with geriatrics.

This handbook is a much needed, and welcome addition to the literature and will serve as an excellent source of reference. This text is recommended reading for all persons concerned with the identification, assessment, and rehabilitation of hearing loss in adults.

Impedance Screening for Middle Ear Disease in Children. Edited by E. R. Harford, F. Bess, C. D. Bluestone, J. O. Klein. Grune &

Stratton, pp. 303, 1978.

Reviewed by:

Jerry L. Northern, Ph.D.

This text is actually the proceedings from an international symposium held in Nashville, Tennessee in June of 1977 co-sponsored by Vanderbilt University Medical School and Maternal and Child Health Services. The book contains 24 papers and four comprehensive state-of-the-art papers. The material is divided into six sections including background material of middle ear disease in children, and current research on the use of impedance measurements for screening infants, preschool, school age and special populations of children. The initial chapter in this text contains the important

Recommended Guidelines for Impedance Screening for Children compiled by a Task Force of 28 experts from the fields of audiology, otolaryngology, pediatrics and epidemiology (see *Corti's Organ*, April, 1978). These guidelines are needed by numerous clinicians, school programs and other agency efforts involved in mass hearing screening programs which include impedance measurements.

This text is outstanding and a worthwhile purchase for all professionals involved with impedance screening. The quality of the papers is excellent and much new material is included in print for the first time. The collection of papers dealing with impedance in infants is especially valuable. Although many texts based on symposium proceedings fail to meet expectations, this collection of papers on impedance screening in children represents a substantial contribution to the hearing field.

Katz, J. (Ed.) **Handbook of Clinical Audiology**, Second Edition. Baltimore: Williams and Wilkins (1978), 623 pp.

Reviewed by:

Janet M. Zarnoch

The second edition of this book takes the place of only one other text, and that is the original *Handbook of Clinical Audiology*. Once again, Katz has generated an outstanding collection of chapters dealing with traditional areas of testing and rehabilitation, as well as new developments in the field of clinical audiology.

The book is divided into eleven major sections covering the following areas: Nature of the Problem, Conservation of Hearing, Basic Evaluation, Differentiation of Cochlear and Retrocochlear Dysfunction, Evaluation of Central Dysfunction, Evaluation of Pseudohypacusis, Physiological Tests of Auditory and Vestibular Function, Evaluation of Young Children and the Elderly, Management of the Hearing Impaired, Hearing Aids, and Communication Training. There is a total of 49 chapters, 27 of which appeared in the original text, that reappear in the second edition with revisions and updates. The remaining 22 chapters are composed of original new material. Forty-three contributors, experts in diverse areas of audiology, make each chapter a valuable learning experience for graduate students, teachers, and audiologists, otologists, speech pathologists, and other allied health professionals.

Aside from excellent coverage on new developments in the field, there are definite improvements in some of the areas previously covered in the first edition. Of particular value are the chapters dealing with Otology, Neurology, and General Medical Considera-

tions as well as the two chapters on Acoustic Impedance Principles, and Testing. These particular chapters cover a wide range of clinically useful information and are written on an understandable level. In addition, the chapters dealing with pseudohypacusis, management of the hearing impaired, and hearing aids are very well written and informative. The chapters which discuss traditional site of lesion testing are complete and well defined. The section of the text entitled "Physiological Tests of Auditory and Vestibular Function" would be more informative and current had a separate chapter been added on brainstem evoked response audiometry, rather than incorporating BSER into the Electroencephalic Response chapter.

Furthermore, recognizing that more and more audiologists are beginning to play an integral part in the vestibular evaluation of the dizzy patient, it would have been very appropriate to include a state-of-the-art chapter covering such procedures as the Romberg Test, both clinical and computerized, as well as rotational testing.

This book is a definite must for every audiology student, teacher and practicing clinical audiologist. By far, it presents the most comprehensive review of relevant topics in audiology at the present time. Those professionals who current own Katz's first edition would find it well worth their while to invest in the second edition.

New Team Members

Continued from page 2

should have with either group. Therefore, with the added interest in the training program throughout the country, a decision was made to change the way in which the certification program was run. Rather than have everyone come to Portland, we will go out on the road and certify groups of individuals much like what was done for impedance or what is now being done for brain stem audiometry. In the very near future, hopefully starting in January, this will be accomplished. We recruited Jerry Northern to help us set up a program in which he will also be actively involved. In addition to Jerry, people here at Kresge, and audiologists and otolaryngologists throughout the United States will participate in the training program.

Q.: Whom do you expect to take advantage of these workshops?

A.: These workshops will be primarily for otolaryngologists, audiologists and hearing aid dispensers. The object of the workshop is to teach the masking procedures to members of these three disciplines who may be interested in starting a tinnitus program of their own. The courses will involve evaluation and management of the tinnitus

patient. These workshops will be held throughout the United States in the larger metropolitan areas. There has been a lot of interest in this program and we already have a list of people from many different areas. We found that the AAO was very interested in our program and we also will be represented at ASHA if audiologists want to contact us there.

Q.: Where will you be?

A.: We will be at the special interest tables instead of having a professional exhibit there. Sunday I will be at a table for the American Tinnitus Association and they can get information there. They also can get information by writing to the American Tinnitus Association, P.O. Box 5, Portland, Oregon 97207. There is also a number to call 503-248-9985.

Q.: When and where will these workshops be held?

A.: The plans are to hold the workshops on Thursday evenings from about 7:00-10:00 and the next day for about 7 hours, from approximately 9:00 a.m.-5:00 p.m. At the end of that time people will be certified and have access to the dissemination of instruments through the A.T.A. Also, otolaryngologists will be eligible to receive

credit under the AMA classification and the hearing aid dispensers will get credit through the Hearing Instruments Institute. Tentatively we have a schedule worked out where we will begin here in Portland in January, go to Washington, D.C. in February, be at the Vail Conference in March, and then April in Boston, May in Chicago and Philadelphia in June. The reason we made the decision to go to the east coast is that a lot of the activity through the observer program has been with people from the west coast. So a lot of people from California, Oregon, Washington, Idaho, have already come to Portland, and the main emphasis of the initial part of the program will have to be on the east coast.

Q.: What do you see as the future for the Tinnitus Clinic?

A.: As far as what's going to happen in the future we have already begun several research projects and we have talked to many of the people who are involved in research projects. There is so much to learn about tinnitus but with the interest which has been developed over the past few years in this area, we are hopeful that many people in all three disciplines will become actively involved in the program.

Happy Attendees at the 13th Otology-Audiology Workshop at Vail Institute, standing left to right: Linda Blane, Tom Norris, Marsha Simons, Dr. and Mrs. David Hanson, Paul Yanick; and seated, Kathy

Research Report

James Kreul at California State University at Chico is working on a grant from the Office of Education (HEW) entitled "Evaluation of a Method of Hearing Screening of Infants." The work grew out of the previous clinical and laboratory experience gained through a project initiated by HEW with him while he was at SRI. The test stimuli were selected and calibrated at that time and a series of initial studies were conducted and reported. The TV tape recordings of 50 infants were recorded by Dr. Robert Sandlin and his co-workers at the Speech, Hearing and Neurosensory Center in San Diego under Kreul's direction at that time.

The proposed project is designed to evaluate observer's ability to identify stimulus-response chains for infants exposed to auditory stimuli.

The technique of video recording provides material which can be used for objective analyses of an observer's ability to identify a stimulus-response chain. Establishing this chain is

fundamental to disciplines having roots in the behavioral sciences.

The advantages of using a recorded event for analysis are:

First, it permits evaluation of the judgment that a response occurred without confounding that judgment with a priori knowledge that, in fact, a stimulus was presented. This demonstrates objectively the judge's ability to note a response. Second, it permits judgments of the same stimulus-response set by several judges or by the same judge on several occasions, thereby providing estimates of inter- and intra-judge variance. Third, it allows for the determination of behavioral changes associated with the test stimuli. And fourth, the recorded material may be used for training observers to recognize responses that may both lead and mislead a judge to associate a behavior response with the test stimuli. It allows for the objective determination of those behavioral responses associated with stimuli at different age levels.

13th Colorado Otology- Audiology Workshop

The 13th Colorado Otology-Audiology Workshop will be held at **The Mark at Lionshead, Vail, Colorado, March 3-10, 1979.** Theme: **THE EAR.** A distinguished faculty including: Ray Battin, Ph.D., Moe Bergman, Ed.D.,

LaVonne Bergstrom, M.D., Charles Berlin, Ph.D., F. Owen Black, M.D., Richard Bobbin, Ph.D., Robert Brummett, Ph.D.,

Jean R. Causse, M.D., Peter Dallos, Ph.D., Willard Fee, Jr., M.D., Michael Glasscock, M.D.,

Siemens introduces two new hearing aids more versatile, simpler-to-set than ever before.

So simple and versatile, you can actually
adjust the critical hearing controls while your client
is wearing it. All it takes is a screwdriver. Two specially
designed behind-the-ear hearing aids make
it possible.

What's more, you'll find the settings for response
curve, maximum power output and compression
ratio large, positive and independent. Easily
adjustable. More accurate because all controls stop
at either end of the spectrum.

Your customers benefit

The 24 PP-AGC-I, with its very high gain and

its input compression feature, is ideal for those
with serious hearing loss and significant tolerance
problems.

And in our 22W-AGC-PC, we add significantly
to speech discrimination with the broadest range
(200-7600 Hz) in our ear level history.

Any Questions?

To get full details on Siemens new, versatile
hearing instruments, write or call: Siemens
Hearing Instruments, Inc., 685 Liberty Avenue,
Union, New Jersey 07083. (800) 631-7965.

Siemens Hearing Instruments, Inc.

This tamper-proof cover
protects your critical settings.

Easily-adjustable, independent
settings:
Maximum Power Output
Compression Ratio
Response Curve

OTM Switch and
Volume Control.
They both work in the
same direction. Prevents
accidental turnoff by user.

Impulse Noise Standards Needed, Concludes 3rd ICBEN Congress

Report from Freiburg
W. Dixon Ward, Foreign News Letter

Development of an acceptable standard to limit exposure to impulse and impact noise appears to be the most pressing problem we now face, agreed members of the Noise and Hearing Team of ICBEN (International Commission on the Biological Effects of Noise) during the Third International Congress on Noise as a Public Health Problem held at Freiburg im Breisgau, West Germany, on Sept. 25 through 29. Data relating hearing loss to steady noise exposure are now adequate to allow us to specify what exposure limit will restrict hearing to losses at audiometric frequency X to less than Y dB in Z percent of the exposed population, so that most arguments in this area have become quibbling over what values of X, Y and Z "should" be used (for example, read the editorial in the August 1978 issue of S/V). However, the field of impulse noise enjoys no such advanced development. Present exposure limits that merely put a ceiling on the instantaneous pressure of pulses from firearms and devices such as explosive bolt drivers, or the impact noise developed by forging machines, thus ignoring their duration and spectral characteristics, are clearly incorrect. The present USA limit of 140 dB, for example, puts cap guns some 20 dB over the top.

ICBEN is composed of eight Teams that collectively cover the effects of noise (alone or in combination with other baneful influences) on hearing loss, communication, physiological and psychological function, task performance, sleep, and community attitude. Each Team is composed of up to 12 experts in the area concerned, no more than two of whom can be citizens of the same country.

The formal goals of ICBEN are to encourage international cooperation in the study of the biological effects of noise, to promote communication among research scientists, governmental agencies, industrial workers and managers, and others regarding these effects, and to stimulate the exchange and dissemination of information about them. The informal (original) goal is to secure funding for quinquennial Congresses. At these Congresses, each Team reviews the progress, if any, in the past 5 years, gives short synopses of current activity, and discusses the direction that, in their opinion, research should take in the immediate future.

Impulse noise is not, of course, the only problem in the area of noise and hearing. However, it was apparent that little progress has been made in some directions since 1973, when the previous Congress was held in Dubrovnik, Yugoslavia. For example, no breakthroughs seem to have occurred in attempts to predict susceptibility to noise-induced hearing loss or to differentiate hearing losses caused by long-term exposure to steady noise from that caused by acoustic trauma, disease, or aging. Nor has a magic elixir been found that will reduce auditory damage, although encouraging results were reported by R. Bobbin of Kresge South (New Orleans) using AOAA (amino oxyacetic acid) and by Dave Lipscomb with inhaled carbogen (95% oxygen, 5% carbon dioxide).

The lack of correlation, in experimental animals, between the condition of hair cells and the behavioral threshold continues to puzzle all North American investigators. This has led to a search for measures of auditory ability that are more sensitive to slight physiological damage than the pure-tone threshold, a search that is, unfortunately, thus far unsuccessful.

In his review of the Hearing Team presentations, Ross Coles (ISVR, Southampton, UK) stressed the need for studies (1) to test the validity of using only A-weighting to rate noise hazard, (2) to determine the interaction between hearing loss, ear protectors, and response to warning signals, and finally, in agreement with a recommendation of mine, (3) to determine the true incidence of hearing loss in random samples of the population of a country accompanied by a thorough history-taking, so that, by eliminating from this sample all persons with significant industrial noise exposure, one can obtain an accurate estimate of the amount of hearing damage caused by non-occupational noises and by diseases, drugs and industrial chemicals. Coles also discussed the practical problem of getting workers to wear ear protection. A dramatic increase in their use was produced by a program that involved asking workers to wear protectors on one day and not on another, measuring the auditory fatigue on both days, and then showing each member the effect on his own thresholds.

A persistent theme that appeared in several Team presentations was the possible link between noise exposure and hypertension, a relation suggested by the early research of the Chairman of ICBEN and the organizer of the Congress, Gerd Jansen (Mainz, Germany). Paul Knipschild (Amsterdam) reports a greater incidence of hypertension in high-noise (65-70 dBA) than in low noise (55 dBA) areas, measured directly in one study, and inferred from sales of drugs for hypertension in another, and Sheldon Cohen (Oregon) found higher blood pressure in school children near Los Angeles International Airport. On the other hand, Alex Cohen (NIOSH, Cincinnati) found no relation between Hearing Levels and

hypertension per se in workers in a paper-making plant. It is clear that work in this area should be expanded.

The Sleep, Performance and Noise in Wildlife Teams are still struggling mightily to show any long-term or indeed persistent effects at all. For example, gradual adaptation of responses to noise during sleep was found by George Thiessen in Ottawa, Canada, but not by Muzet and Ehrhart in Strasbourg, France. Furthermore, Vallet and Gagneaux (Bron Cedex, France) showed that results obtained in the laboratory are not always confirmed when responses of test subjects are recorded in their own houses. Although the majority of ICBEN members seem still convinced that noise must have some effect on sleep and task performance, the degree of this is obviously still unclear.

By contrast, the Community Reaction Team has no trouble showing that annoyance is engendered by noise. Unfortunately, the degree of annoyance, although to some extent dependent on a host of know factors, is still so unpredictable in the specific individual that only group tendencies can be relied on. Indeed, measurement of annoyance itself is such a difficult problem that most investigators in the Congress were content to merely divide respondents into two groups—the "highly annoyed" and the remainder. In my opinion, the most interesting development in this area was the demonstration by J. B. Ollerhead (Loughborough, UK) that the 10-dB nighttime "penalty" used in the USA for calculating annoyingness is probably far off the mark. Instead of a 10-dB penalty for noises occurring between

10 p.m. and 7 a.m., as calculation of our Ldn dictates, his study suggests that we should attach only about a 5-dB penalty to noises between 6 p.m. and midnight or 1 a.m.—the TV-viewing hours (among other activities)—with the rest of the night left unpenalized.

As there were no parallel sessions, business took so much of our time—usually at least 10 hours a day (IRS take notice)—that the only social event was a banquet-dance on the last night of the Congress. However, this typical Schwarzwald festivity made up in quality for the lack of quantity, and proved that Munich is not the only place to find Gemutlichkeit during the last week in September.

At the business meeting of ICBEN, the Team Chairmen and Co-Chairmen adopted a formal constitution and elected new officers for the next 5 years. Jerry Tobias, member of a well-known piano duo, was elected Chairman; Henning von Gierke will be Co-Chairman, and Jan van den Eijk (Netherlands) the Secretary-Treasurer. The proceedings of the Congress, to be edited by Tobias, Jansen and myself, will appear as an ASHA monograph by, we hope, next spring.

The next Congress is planned for 1983, perhaps in Turin, Italy, or somewhere in France. It is hoped that firm plans can be made within a couple of years, so that perhaps next time we may be able to secure premission from Russian authorities to let some of their citizens out the country for a week; although we had invited several Russian scientists, and they had accepted, apparently a year (actually, well over a year) is not enough time to get through the Soviet red tape.

Bells Are Ringing . . .

Continued from page 6

developed specifically for tinnitus. Biofeedback has also been reported to be successful in treating tinnitus.

Q.: Why would patients accept masking? Why would patients object to their internal sound and yet accept an external sound?

A.: To many patients and to many physicians it does sound like a weird state of affairs. I have listed three reasons why I thought masking was indeed quite acceptable to the patient. And they were, first, that it was an external sound an uninteresting sound and we can routinely shut off external sounds when they are not interesting to us. And if we can cover up a patient's tinnitus with an external sound he will automatically ignore his tinnitus, something that is very hard to do normally, such as in severe tinnitus. Secondly, most of the tinnitus is in high pitched tones, shrill, piercing, screeching high pitched sounds—acoustically that is quite unacceptable. We cover that up with a band of noise and it is much more acceptable, much more pleasant and easier to take than that piercing tone. Then the third reason, which is psychological, is that for the first time it gives the patient an element of control over his tinnitus. By adjusting the balance of the masking sound they have control over their tinnitus which they have never had before.

A recommended bibliography on tinnitus is as follows:

THE SECOND SYMPOSIUM ON THE APPLICATION OF SIGNAL PROCESSING
CONCEPTS TO HEARING AIDS

March 23-24, 1979

SPONSORED BY: Pennsylvania State University, Speech Pathology and Audiology Dept.

CHAIRMAN: Paul Yanick Jr., M.A.

THEME: Rehabilitation of Sensorineural Hearing Loss

SPEAKERS:

This symposium is intended for all members of the hearing health care team concerned with improvement of current hearing aid fitting and post-fitting procedures. Practical application of the latest research on hearing aids and rehabilitation will be emphasized. Topics include: post-fitting counseling and assessment of communicative function, micro-processor based signal processing, speech spectrum relationships to the impaired ear, critical band

measurements for use in hearing aid fittings, binaural hearing, metabolic and allergic dysfunction in sensorineural hearing loss, practical application of the latest research at C.I.D., new circuit design concepts for future hearing aids, and electrostimulation of the cochlea as a non-invasive approach to rehabilitate sensorineural hearing loss.

New Institute Hearing Help Booklets Offer Hope to Nerve Deafness/Tinnitus Sufferers

WASHINGTON, D.C., (October 9, 1978) "Nerve Deafness and You" by Gale Gardner, M.D., and "Tinnitus, or Head Noises" by Norman Lee Barr Jr., M.D., F.A.C.S., new booklets now available from the Better Hearing Institute, help dispel myths and provide much needed information

on two major hearing disorders affecting more than 40 million Americans.

Sponsored by a special supplemental grant from Knowles Electronics, Inc., the attractive, and easy-to-read booklets should be very helpful to members of the hearing health

team in their public information efforts. Both brochures can be used by otologists, otolaryngologists, general practitioners, hearing aid dispensers, audiologists, schools, service clubs, and others for distribution in waiting rooms, mailings, at speaking presentations, in displays, and so forth.

"Nerve Deafness and You" describes the disorder, the hearing process, warning signs, corrects common myths and misinformation, and explains what to do and where to go for help.

"Tinnitus, or Head Noises" covers the magnitude of the problem, causes, and treatment, including medication, hearing aids, and tinnitus masking devices.

"BHI" feels these new booklets—the first in a series of brochures to be developed by the Institute—greatly enhance our efforts to inform the hearing impaired and others about hearing disabilities and what to do about them," said BHI Director Joseph Rizzo. "Topics currently underway," he added, "include the hearing aid, conductive disorders, noise-induced hearing loss, and prevention."

"Nerve Deafness and You" and "Tinnitus, or Head Noises" are available for \$10 per 100 from the Better Hearing Institute, 1430 K Street, N.W., Suite 600, Washington, D.C. 20005. (See order form). Single copies are free on request.

The Better Hearing Institute is a nonprofit educational organization dedicated to informing the hearing impaired, their families and friends, and the general public about hearing loss and hearing help.

Continued from page 7

Gerber and his colleagues at the University of California at Santa Barbara have written a text on infant audiometry in which they attempt to provide a comprehensive review of the dilemmas we all face in defining, identifying, and alleviating the effects of hearing loss in children. This team should be acknowledged for assuming such an overwhelming undertaking. As stated in Gerber's own words "...at first I had thought to write the entire book myself. ... then I decided to solicit contributors and looked about for the most qualified people. ... I am very proud that these people turn out to be my own colleagues at the UCSB Speech and Hearing Center."

There are 16 chapters in this book beginning with 4 chapters covering epidemiology and pathology of hearing loss, high risk conditions, and auditory development. The next 7 chapters deal with behavioral and physiological tests of auditory function. The remaining 5 chapters discuss the consequences of hearing impairment in such areas as speech, language, social, and emotional development.

The topic of physiological testing techniques is very well covered in this text, particularly the chapter on Electroencephalic Tests of Hearing written by Maurice Mendel, Ph.D. The chapter on behavioral testing techniques seems to be lacking in information and specifics. The book emphasizes physiologic measures in the area of testing children, when in fact it is behavioral techniques and not physiologic measures that are most often used clinically. It would have been valuable to include more information on how various behavioral techniques are utilized in practical application.

The chapters dealing with the consequence of hearing loss add a great deal to this text in terms of gaining a greater understanding and compassion for what the implications of hearing loss really are.

The well-done photograph on the first page of the book shows a

happy, smiling infant undergoing brain stem evoked response audiometry (but the leads aren't connected...). However, many of the other photographs throughout the text are poorly reproduced, and provide little additional information e.g., the photograph on page 91 showing a duck sitting on a speaker.

This text will serve as a source of obtaining an overview of hearing in children. However, the audiologist will need to supplement this text with other more complete writings on the subject.

Staab, W. J. Hearing Aid Handbook. Blue Ridge, Pa.: TAB Books, (1978), 327 pp.

This "easy to read" handbook provides a description of hearing aids in general, hearing aid components and their functions, methods of measuring and expressing hearing aid performance, ear mold coupling systems and their effects, servicing and maintenance of hearing aids, special amplification devices, as well as a chapter on "the decibel".

The book provides a complete review of the current status of amplification as it applies to hearing aids. The diagrams, tables and pictures are numerous, easy to read and supportive of the text.

The 334 page book is ideal for the library of anyone dealing with hearing aids. The text goes into more detail concerning hearing aids than what is usually covered by most formal training programs, information pertinent to the proper handling of hearing aids and their accessories. The author points out that in no way is the text intended to serve as a guide to the application of a hearing aid to specific pathological conditions or hearing losses. Rather, the purpose of the book is "to provide information about the contemporary hearing aid for the individual who has more than a passing interest in the electrical amplifier as it is used to serve the hearing impaired population".

"IV INTERNATIONAL SYMPOSIUM ON ACOUSTIC IMPEDANCE MEASUREMENTS"

Lisbon, Portugal, September 26-27-28 / 1979
(Calouste Gulbenkian Foundation)

The topics of the Symposium will include:

- 1) Impedance screening in children
- 2) Tympanometry
- 3) Acoustic and Non-acoustic reflexes
- 4) Eustachian Tube evaluations
- 5) Other applications of acoustic impedance measurements

The Symposium will be divided into:

-Lectures	40 minutes
-Exposures	20 minutes
-Free papers	10 minutes
-Round tables	

The following invited guests will be present:

J Barajas (Spain), DN Brooks (UK), VonCamp (Belgium), Djupesland (Norway), Alan Fedlman (USA), G Frey (France), M Gersdorff (Belgium), J Holmquist (Sweden), Niemeyer (West Germany), G. Linden (Sweden), A G Moller (Sweden), J L Northern (USA), T Marulo, A Bosatra (Italy), T Brask (Denmark), and I Eliachar (Israel), F Olaizola, Alaminos (Spain), Orozimbo Costa, Otacilio F, D Menon (Brasil).

Languages: the working languages will be: Portuguese, English, Spanish and French.

CORTI'S ORGAN

The Official House Organ of the American Auditory Society

Vol. 4, No. 1

January, 1979

A Feast of Auditory Science Features Annual Meeting

Program Chairpersons John Sinclair and Terry Grekin presented a rare offering of scientific papers at the annual AAS meeting in San Francisco. Members agreed that it was the most stimulating program of the Society's 5-year existence. There was something for everyone in the recondite of offerings. And Sinclair, as he introduced the speakers, added a lively wit that gave a special flavor to the meeting. John and Terry are to be highly commended for their excellent conducting of the entire program. Abstracts of many of the papers are to be found in this

issue and others will appear in later issues of Corti's Organ. A number will be published in full length in the *Journal of the American Auditory Society*.

President Blair Simmons presided at the brief business meeting of the Society. The minutes of the meeting are on page 6.

At the conclusion of the business meeting Evelyn Inn of Hawaii presented President Simmons with a Hawaiian lei and the traditional greeting.

President Simmons Leaves Office

As of this month President Blair Simmons turns the reins of office over to Sam Lybarger. He joins a distinguished, if small, group of ex-prexies: Aram Glorig, Dix Ward and Geary McCandless. At this time Corti's Organ would like to thank Blair for his responsive and responsible handling of the office. Whenever he was requested to submit or report an article, or to respond to some apparent need in the organization, he did so promptly and effectively, with sensitivity, judgment and humor. It is rare in a man with such demands on his time to give complete attention to this type of organization, but perhaps he is just illustrating the 2nd corollary of Murphy's Law: "If you want anything done, ask the busiest man to do it".

So we are going to ask Blair again and again, to contribute his talents to this Society. That's the way to get things done.

Reger Charms New Generation At AAS Meeting

Scott Reger

Scott Reger, who was a Complete Audiologist long before many of his listeners were born, intrigued an audience of younger scientists with fascinating tales of the early days of audiology. In accepting the Carhart Memorial Award at the AAS annual meeting in San Francisco he gave a truly memorable address to the more than 200 members in attendance. He disclaimed having been the First Audiologist in the U.S., despite the fact that his writings appeared in the early 30's. Cordia Bunch, he insists was a true audiologist even before Reger began to practice.

President Blair Simmons introduced Scott Reger with amusing sidelights of Reger's life. A picture of Reger's office showed an enormous number of manuscripts piled upon each other, none of which was ever published. In those manuscripts probably reposed more knowledge than any single audiologist now can boast. Simmons also mentioned Reger's great love for classical music, resulting in his wiring his large home so that high fidelity stereo reception could be obtained in any room in

(Continued on page 2)

Sam Lybarger, New President Of AAS

Sam Lybarger

In January the new president of AAS, Sam Lybarger, takes office for the year of 1979. Lybarger has devoted a lifetime to the hearing aid industry, and is highly respected in acoustic scientific circles for his contributions to the raising of standards in the auditory prosthetic field. A modest, low-profile type of person, Lybarger is known as one of the hardest working members of any committee or council he has served on. AAS has benefited from his advice and guidance on the Executive Committee and from his thoughtful suggestions in compiling the new By-Laws of the organization. The membership should know more about this fine human being who is our new president. A review of his accomplishments shows that he was a real pioneer in the field of hearing aid engineering, having originated innovative designs that are now considered standard features for hearing aids.

Sam Lybarger was graduated from Carnegie-Mellon University with a B.S. in Physics. A native of Pennsylvania, he had in grade school become interested in electronics through the crystal radio, precursor of the vacuum tube radio. By high school he was a ham radio operator, presaging his life-time preoccupation with electronics.

During two summers of his college years he worked in the Radio Receiver Labs of Westinghouse. The last summer he was employed part time by E.A. Myers and Sons, the

company which later became the Radioear Corporation. His association with this company was to continue for 50 years, so he celebrates in February 1979 a golden anniversary with Radioear. He was permanently employed there following his graduation, chiefly in hearing aid engineering and design.

Lybarger holds 22 patents which were awarded on a master hearing aid design, dated 1938. This certainly pre-dates any other Master Hearing Aids in the industry. In 1946 he was awarded a patent for a magnetic microphone, and produced commercially the first hearing aid with a magnetic mike. In that same aid was the first telephone pick-up in a wearable hearing aid, pre-dating by eight years the use of telephone pick-ups by other makes of aids.

For many years Lybarger served Radioear as its president and retired in 1973 from that post. Since then he has been active in consulting work related to the field. His professional organizations, in which he is still busily participating, include:

Tau Beta Pi, honorary engineering fraternity
Acoustical Society of America—since 1932
International Audiology Society
Institute of Electrical & Electronic Engineering (Senior Member)
Audio-Engineering Society: Fellow
American Auditory Society:

DE REI ERRATA

An informal house organ like Corti's is bound to come up with more printing errors than are found in more formal journals. Published off the top of the heads of its two editors, and bounced back and forth between Denver and Dallas, a great many typos and other errata are committed in the process. But there are some that can be ascribed only to human error. Some people call it carelessness.

One such error is the misprinting of the dates of two important meetings in the *Calendar of Events*. The 2nd International Symposium on Otitis Media with Effusion, Columbus, Ohio and the International Symposium on the Hearing Impaired Child, are on May 9-11 and May 17-19, respectively. Not in April, as shown in the *Calendar*. This error can be ascribed only to the growing senility of the senior editor, who is at some indeterminate point between the age of consent and the age of decay. At this stage of life, details

Reger Charms . . .

(Continued from page 1)

the house. Reger received resounding ovations both before and after his lecture.

Reger described the beginnings of audiology in the laboratories of the University of Iowa. There Reger worked with Seashore, one of the great early scientists concerned with sensory phenomena. In that laboratory the recruitment phenomenon was first observed and recorded, even though Fowler was the first to report it in the medical literature in 1938. And Reger also gave his version of the origins of the term "Audiology". Raymond Carhart figured largely in those origins, and Reger spoke at length of Carhart's great contributions to the field. But it is impossible to reproduce Reger's classical accounts of those early days. Readers will have to await the publication of the entire address in a forthcoming issue of the *Journal of the American Auditory Society*.

Following the address President Simmons presented Reger with the Carhart Award:

the plaque, shown here, and a \$500.00 check. The Society members agreed that it was a great honor to have Reger as their featured speaker and awardee.

Following the day's program an informal dinner party was held at one of the Chinese restaurants so that members could become better acquainted with this distinguished scientist and delightful raconteur.

Carhart Plaque

Letter from England

By Imre Friedmann

Dear Editors,

I have begun writing this letter in Israel but I have now returned from that beautiful and sorely tried country. Memories abound of wonderful Jerusalem always in the focal point of events affecting the entire world. Whilst the leaders argue, the men in the street of various races and nationalities seem to be getting on well together. Notably they sit or stand side by side in the usually overcrowded buses racing through the narrow streets of Jerusalem or on the motorways. These buses seem to have an unlimited capacity and an apparently unending stream of passengers can be absorbed. I have been travelling on one of these horrors every morning and we raced to the famous Hadassah Medical School where I have worked in the very busy and friendly Department of Pathology of my good friend Sam Laufer. He was the President of the recent 12th Congress of the International Academy of Pathology held in Jerusalem in September 1978. A notable and very successful event

are not attended to with the same meticulous devotion as they were in the hot flush of youth.

But the junior editor, full-blooded and able-bodied, pulled off the real boner-of-the-year. Following an excellent report by Jim Kreul of a serious and important research project in process, this editor placed a filler stating "A research project that is not worth doing at all is not worth doing well". Well, Jim, we apologize for this unfortunate juxtaposition. We just didn't see it, in our haste to get the issue to its final printing.

But we assure you that each issue of this bloomin' paper is a labor of love. We enjoy every inch of it. Even the Errata.

—MPD/RJR

which has attracted world-wide attention.

I have found much interesting material on the pathology of the ear and the sections confirmed my own observations on the principal pathological features of otitis media and its complications. The Department of Otolaryngology has been my other home and its staff under Professor Feinmesser has joined the pathologists at my lectures on the 'Pathology of the Ear and Nose'. I have much enjoyed. Perhaps so has the audience because they have most kindly sent me a beautiful book by Chagall on his famous Jerusalem windows. These are attracting thousands of tourists to the Synagogue of the Hadassah Medical Centre with its twelve stained-glass windows designed by the great Chagall. Symbolizing the twelve ancient tribes of Israel in glorious colours, they are among the most inspiring and beautiful examples of 20th century art.

It was a privilege meeting with your old friend, the renowned audiologist, Lilly Tell whose work on deaf children is so well known.

The visitor is attracted by the sad memorial of the Nazi Holocaust, the Yad Vashem, and the survivor cannot rid himself entirely of a sense of guilt. This melancholic place is separated from another, the Military Cemetery, by the peaceful and beautiful Herzl Park where lovely Israeli children have been playing in the brilliant sunshine oblivious of the dark political shadows.

The prevailing mood has remained one of hope and fear and this writer could not help remembering the Munich crisis in 1938 when another small country 'nobody knew or wanted to know about' had occupied the stage of history. Perhaps Israel will be more fortunate!

Sam Lybarger . . .

(Continued from page 1)

Past Executive Committee Member and President, 1979

Lybarger has been one of the most active contributors to the Audiometric Standard field and to the Hearing Aid Industry, in the capacity of presiding officer and committee member in various groups. He was President of the Hearing Aid Industry Conference (HAIC) from 1967 to 1969 and of the Hearing Aid Foundation from 1975 to 1977.

His greatest and most effective scientific contributions have been in the area of standards. Since 1945 he has been active in establishing both audiometric and hearing aid standards. He helped to write the first hearing aid measurement standards in 1945, as a member of the Standards Committee of the American Hearing Aid Association (the first trade association). This standard was the first of its kind in the world.

In 1951 Lybarger became a member of the American Standards Association's writing group that was responsible for establishing the first audiometric standard, the Z-24.5. Since then he has chaired all the writing groups that have produced this country's hearing aid standards.

Retirement from the presidency of Radioear seems to mean even more activity for Lybarger in scientific groups. He is presently chairman of two working groups of the American National Standards Institute (ANSI): Working Group S3-48 and

Working Group S3-43. The latter is concerned with the calibration of bone vibrators. He was appointed to these working groups as a member of ANSI's Committee on Bioacoustics, S-3.

Lybarger is also presently an active member of Working Group 6 of the International Electrotechnical Institute's Technical Committee 29. This group is concerned with hearing aid standards.

Among Lybarger's over 25 publications are chapters in Katz's *Handbook in Audiology*, in Donnelly's *Interpretation of Hearing Aid Technology*, and in Frisina's *Bicentennial Monograph on Hearing Impairments*. Most of his articles, in the technical journals here and abroad, are concerned with Hearing Aid Measurement, Ear Mold Design, Hearing Aid Standards, and Bone Conduction measurements. In addition, he has given countless talks on these subjects before various organizations.

Lybarger lives in McMurray, Pennsylvania, which is 16 miles SW of Pittsburgh. He is married to the former Alberta Myers with whom he has a son, Edward, who has a retail hearing aid sales offices in Pittsburgh. Edward works on sales exclusively for audiological clinics and medical schools.

Hobbies for Lybarger include his greatest love, hearing aids, and as a close second, photography.

Some news from England. The Hearing Research Institute of the Medical Research Council is alive and active as so well described by its Director, Dr. M.P. Haggard in the *Journal of Laryngology* who ends his report on a philosophical note accepting that 'the delays between inception of planning in

1976 to effectiveness in 1979-80 have conferred benefits as well as frustrations'.

Finally back to you. Wintersport and Otolary seem to go hand in hand. Your pioneering symposia in Vail seem to have been copied by others in the USA and in Canada. How I envy you all.

Corti's now has Advertising Manager

Terry Stark, an attractive audiologist from the Cajun state of Louisiana, has accepted the post of Advertising Manager of Corti's Organ. Terry is very enthused about her new responsibilities and has started a

campaign to increase advertising in the publication. So, you potential advertisers, don't be surprised if you hear from her soon. Her address is: Terry Stark, 2121 Line Avenue, Shreveport, La. 71104.

Terry Stark

New Journals Proliferate

Three major journals are appearing almost simultaneously in the auditory spectrum: An American Journal of Otolaryngology, an American Journal of Otolaryngology and an International Journal of Pediatric Otorhinolaryngology. Each in its way has some unique aspects that fill voids in the otolaryngology field. As each will include a great many articles relevant to the auditory field, it is important for AAS members to be acquainted with the purposes and editorial policies of these new publications.

The International Journal of Pediatric Otorhinolaryngology. Editor-in-Chief, Professor Robert J. Ruben, The Albert Einstein College of Medicine.

Aims & Purposes

There is a need to bring together the many different contributions in the field of pediatric otorhinolaryngology. At the present time, the scientific and clinical reports concerning infants and children are to be found in a large number of different journals in different disciplines. As a consequence of this, much of the information concerning otorhinolaryngological disorders of infants and children is either delayed in its application or, in many instances, is not known to those who can best utilize the new findings in the delivery of health care to infants and children. Furthermore, there is a special need for a publication of advances in the area of pediatric otorhinolaryngology. Many of the habilitative medical and surgical interventions will affect the child throughout his or her entire life. What is done for the infant or child, especially in the area of communicative disorders, will have far-reaching and substantive influence throughout the course of the person's life in terms of linguistic and cognitive development. The long-term effects of interventions is also true of other areas, e.g. in laryngology. There will be, by means of the International Journal of Pediatric Otorhinolaryngology, a way to make readily available the significant advances in the field so that their utilization may come about without delay by all those involved in pediatric otorhinolaryngology.

The purpose of the International Journal of Pediatric Otorhinolaryngology is to concentrate and disseminate information concerning prevention, cure and care of otorhinolaryngological disorders in infants and children.

These disorders include those which are in whole or part due to developmental, degenerative, infectious, neoplastic, traumatic, social, psychiatric, and economic causes. The Journal will publish the clinical and basic contributions in all of the areas of pediatric otorhinolaryngology. This includes medical and surgical otology, bronchoesophology, medical and surgical laryngology, medical and surgical laryngology, medical and surgical diseases of the head and neck, and diseases of communication, including voice, speech,

and language disorders. All original contributions will be reviewed by recognized national authorities competent in the area. The editorial board will then act upon the reviewer's recommendations. From time to time there will be contributions which will be invited by the editorial board. These contributions will bring together information which is of importance to the pediatric otorhinolaryngological community, so that they may better carry out their work in the creation and application of new knowledge to the delivery of health care of otorhinolaryngology in infants and children.

Editorial Policies: The International Journal of Pediatric Otorhinolaryngology actively encourages contributions from the many disciplines concerned in the area. The editorial policy of the Journal will be such as to provide useful information for all the areas of pediatric otorhinolaryngology which include general pediatrics, neonatology, community medicine, otorhinolaryngology, public health, audiology, speech, linguistics, developmental pediatrics and pediatric neurology. Individuals in all of these areas are invited to submit articles and/or suggestions to the Editorial Board of the Journal. All contributions and correspondence should be sent to the Editor in Chief, Professor Robert J. Ruben, Professor and Chairman, Department of Otorhinolaryngology, The Albert Einstein College of Medicine, 1300 Morris Park Avenue, Bronx, New York 10461.

The American Journal of Otolaryngology

Ed: Michael Glasscock, M.D.
Nashville, Tennessee

Aims & Purposes:

This journal proposes to be clinically oriented in all its aspects. It will be aimed at the clinical otologist, audiologist, neurotologist, and neurosurgeon. Because of its clinical nature, scientific papers will be accepted only as they apply to clinical practice.

The Journal will be published quarterly in January, April, June and October. Its Editor, Dr. Glasscock, has appointed an Editorial Board of 29 otologists, audiologists and neurosurgeons. Barbara Bryant will be the Managing Editor.

Editorial Policies:

This journal is unique in that it will have regular features in which either submitted papers or invited papers will be printed. These features include:

- A Forum Section: for readers to write in and give opinions about articles, or to discuss subjects that are controversial in the field.
- A Residents Forum: with submitted or invited articles by residents.
- A Section on Instrumentation.
- A Historical Section with an article on an early person or technique in the field.
- A Case Report in every issue.
- A Doctors' Discussion Section: this will feature a tape from the regular doctors' discus-

sions of the Otolaryngologic Medical Group. Clinical Cases are covered, with the attending physician's analyses.

Submittals should be sent to: American Journal of Otolaryngology, c/o Dr. Michael Glasscock, 1811 State Street, Nashville, Tennessee 37203.

American Journal of Otolaryngology. Editor-in-Chief, James B. Snow, Jr., M.D., University of Pennsylvania School of Medicine, Philadelphia. Publisher: W. B. Saunders.

Aims and Purposes: This Journal is aimed at otolaryngologists, audiologists, speech pathologists and other related disciplines. The Editorial Board is composed of Otolaryngologists, Audiologists, Speech Pathologists, Anatomists, Physiologists, Pathologists and Biochemists. Both basic and clinical research articles will be solicited, and its interest lies largely in research reports.

Editorial Policies: Original articles are solicited, and there are also other sections of note:

- Review articles on Basic Science or clinical topics on an invited basis.
- Abstracts of non-otolaryngologic literature.
- Book reviews of all relevant topics.
- Correspondence
- Editorials

Submittals of papers should go to: James B. Snow, M.D., 3400 Spruce Street, Philadelphia, Penn. 19104.

New England Medical Center Sponsors Workshop

The Communication Disorders Seminar Series sponsored by the Speech, Hearing and Language Center of New England Medical Center Hospital will be sponsoring two full-day workshops for audiologists.

On April 27, 1979, Laszlo Stein (Director, Siegel Institute, Michael Reese Hospital), will be presenting a workshop entitled "Brain Stem Evoked and Other Electrophysiological Tests" (workshop 9:00 a.m.-5:00 p.m.).

On June 22, 1979, Sanford

Gerber (Professor of Audiology, Coordinator of Speech and Hearing Science, University of California) will be presenting a workshop entitled "Infant Testing (Audiology)" (workshop 9:00 a.m.-5:00 p.m.).

For further information and registration material please contact Hubert Gerstman or Sharon Weiss-Kapp, New England Medical Center Hospital, Speech, Hearing and Language Center, 185 Harrison Avenue, Boston, MA 02111; (617) 956-5300.

Proceedings of past conferences are available

The Institute of Noise Control Engineering has sponsored a series of International Conferences on Noise Control (the INTER-NOISE series) and a series of National Conferences on specialized topics in noise control (the NOISE-CON series). To date, seven International Conferences (one each year, 1972-1978) and three National Conferences ('73, '75, '77) have been held. INTER-NOISE 79 will be held in Poland in September of 1979 and NOISE-CON 79, with the theme "Machinery Noise Control," will be held at Purdue University in

West Lafayette, Indiana on April 30-May 2 1979.

A limited number of copies of all of the Proceedings of past Conferences are still available, including the Proceedings of the International Conferences held overseas in Copenhagen in 1973, Sendai (Japan) in 1975 and Zurich in 1977.

Information on the contents of each volume, prices, airmail surcharges and other information may be obtained from the Institute of Noise Control Engineering, P. O. Box 3206, Arlington Branch, Poughkeepsie, NY 12603 U.S.A.

Clinical Applications of Brainstem Auditory Electric Response Testing at a Children's Hospital

Kenneth M. Grundfast
Thomas J. Fria
Victoria Bartlina
Diana Sabo,

Univ. of Pittsburgh School of Med.
Pittsburgh, Pa.

Experience with the use of the brainstem auditory electric response (BSER) test utilized for 239 children over a two year period has been reviewed. The children tested varied in age from one month to 18 years, but most were 6 months to 6 years of age.

The majority of children were referred for BSER testing by pediatricians, otolaryngologists, and audiologists. Comparatively smaller numbers were referred from neurologists, school personnel, and speech pathologists. About half of the children were referred for BSER testing because behavioral audiometric tests could not be done, or because equivocal behavioral results were obtained. These children, together with infants referred because history or physical findings indicated a significant risk for hearing loss, comprised 61% of the population tested. The remaining 39% of the children underwent BSER testing to aid in localizing a site of lesion; to document, quantify and serially assess sudden sensorineural loss; to determine the effect on hearing of an observed otitis media with effusion; or to detect a possible impairment in hearing associated with meningitis or autism.

In reviewing the total experience, it is difficult to make a bold and definitive statement about the usefulness of BSER testing at a hospital for children. Rarely did the BSER test, itself, establish a diagnosis that could not have been ascertained by some other method. Rather, the BSER provided supplemental, adjunctive and confirmatory types of information. The BSER test seemed to be most useful in the situations where it was most difficult to acquire any objective assessment of a child's hearing, CNS function, or both. Also, it appears that the BSER test has merit in the diagnosis of ill defined neurologic disorders.

That is, the combination of BSER testing with such other objective neurologic tests as manometric esophageal motility studies, visual evoked response tests, and electrical tests of balance and posture control may add to the relative significance of BSER findings. The collective analysis of findings on several different types of tests can give a picture of localized brainstem pathology, isolated auditory system involvement, or generalized central nervous system malfunction caused by delayed maturation or degeneration. In summary, when a multiplicity of concurrently occurring problems makes diagnosis and management difficult, then BSER testing may be able to provide needed information at least about the integrity of one sensory system and a portion of the central nervous system.

Threshold Prediction Based on Motor Reaction Time

Clifford C. Olsen
Central Michigan University
Mt. Pleasant, Mich.

Reaction time procedures have evolved from animal psychophysics where it is particularly difficult to obtain a specific behavioral response to a supra threshold stimulus that is independent of a reinforcement schedule or other variables. As is often the case, the experimental design influences the animal's report of the stimulus more so than the sensory input itself (Moody, 1970). Reaction time, however, tends to covary with stimulus changes without any specific training. Variations in response latency change in a lawful manner with respect to changes in stimulus intensity. The latency with which a simple motor response occurs in reaction to acoustic stimuli has been shown to be a valid index of the loudness of such signals. Application of this technique to generating equal loudness contours is well documented (Stebbins and Miller, 1964; Stebbins, 1966; Pfingst, Hienz, Kimm and Miller, 1975). The present investigation sought to predict auditory threshold sensitivity directly from the function relating signal intensity to reaction time.

Normal hearing subjects were seated in a sound treated booth wearing the standard audiometric earphone arrangement. They faced a display light panel and a telegraph key and were instructed to depress the key upon the onset of the "ready" light. Depression of the key initiated a random time interval followed by the onset of a tonal stimulus to the right earphone. A subject's task was to release the key as quickly as possible upon tone onset. RT then became a measure of the latency between tone onset and key release. Monaurally presented stimuli of the 250, 1000 and 4000 Hz were randomly presented in 5 dB steps between 100 and 0 dB HTL.

The reaction time functions obtained from 30 normal hearing adults displayed no frequency effect. The function is best described as a negatively accelerating hyperbolic curve where reaction time increased with decreasing signal intensity. The data can best be represented by an equation of the form: $Y = aXb + C$ where Y corresponds to signal intensity, X to reaction time, and C is a constant corresponding to asymptote. The traditional plot of latency and intensity is such that latency is scaled on the ordinate and intensity along the abscissa. If these axes are reversed it is found that the reaction time function reaches an asymptote as a hearing level corresponding to auditory threshold. The invariance of these functions across normal listeners prompted the question: Will the intensity-latency function likewise reach an asymptote at a hearing level corresponding to threshold in the hearing impaired ear? To test this, intensity-latency functions were obtained from 10 hearing-impaired adults (non conductives) at three test frequencies.

Based solely on intensity-latency functions, threshold sensitivity of the hearing impaired ears was then predicted. Threshold predictions varied by no more than + 10 dB from the value obtained audiometrically. The significance of these predictions lies not in the accuracy of the predictions per se but that the reaction time function displays an invariance across the normal hearing and most sensorineural ears that enables the prediction to be made. Obviously, the same threshold information could be obtained from a reaction time trial by noting simply the signal intensity where a listener ceases to respond.

Since the intensity-latency function is characterized by an asymptote corresponding to threshold it seemed logical that in an individual feigning a hearing loss the reaction time function would not reach an asymptote. Accordingly, it was found that the intensity-latency functions obtained from three malingerers did not asymptote, most likely because the listeners ceased to respond to signals beneath a certain intensity level; not however corresponding to auditory threshold. Similar functions were obtained from normal listeners instructed to "fake a hearing loss."

In the final analysis, the clinical application of this particular reaction time procedure appears limited. The elaborate instrumentation needed, the practice required of naive listeners and the availability of established tests for non-organic contribute to the procedure's restricted clinical utility.

As a research tool, latency-intensity functions continue to provide information about auditory processing. In the CMU laboratory we are attempting to apply reaction-time data to the prediction of the hearing loss using the same rationale that is used to predict hearing loss from the acoustic reflex; namely the differential loudness summation evidenced from noise and tonal stimuli. If reaction times are sensitive to noise-tone loudness differences we may be able to predict hearing loss from a comparison of reaction time differences between broad band noise and tones from normal hearing and sensorineural listeners.

Application of reaction time to the study of issues in speech perception, loudness growth, fatigue recovery processes, and recently to the study of monaural loudness adaptation suggest that the study of reaction time as it relates to acoustic events may have increased significance in the future.

Hearing Loss Following Meningitis

Ulf Rosenhall
Goteborg, Sweden

Purulent meningitis is one of the most common causes of acquired sensorineural hearing loss or deafness in childhood. A retrospective study was initiated at the department of Audiology, Sahlgren's hospital, Gothenburg, Sweden. In order to study this

type of meningitic hearing loss.

Our files were searched for all cases of meningitic hearing loss tested at our department since the 1950s. We found altogether 68 individuals, mostly children, with hearing loss which could be related to purulent meningitis (Fig. 1). About half of the patients, 35 in number, had suffered from Haemophilus influenzae meningitis. Twelve had had Meningococcal meningitis. In 1 case the etiological agent was Staphylococcus aureus and in 3 cases the bacterium was unknown.

Concerning the Haemophilus influenzae cases, severe hearing loss was rather common, but remnants of hearing were usually present. Total deafness affecting both ears was only seen in five cases.

Also, after Meningococcal meningitis, a majority of the cases had some residual hearing, and in some instances the hearing loss was only slight.

Pneumococcal meningitis, on the other hand, showed a gloomy picture: Out of 12 patients with hearing loss following this dreaded disease 9 were totally deaf.

A large number of cases altogether 21 patients, had unilateral hearing loss or deafness with normal hearing at the opposite ear.

Also, many patients with slight or moderate hearing loss in one ear, exhibited severe hearing loss or deafness at the other ear. Characteristically, many of the patients with auditory sequelae after meningitis have asymmetrical hearing loss with one better and one worse ear. The pure tone thresholds often have an irregular saw-toothed appearance. Sometimes there are quite considerable differences of the hearing at neighboring frequencies, and some cases show a steep hump of normal or nearly normal hearing at 2000 or 4000 Hz.

In eight cases the meningitic hearing loss improved in one ear or in both ears between one to nine months after the disease. In some instances this improvement was considerable, in others only moderate.

The opposite condition, deterioration of hearing, was also observed in some instances. In five cases such deterioration was noticed about six months after the disease. In most of these cases hearing loss was already observed soon after the disease, and this hearing loss eventually grew worse. One patient however, had normal or nearly normal hearing directly after Haemophilus influenzae meningitis. The hearing rather suddenly dropped about half a year after the disease, and the hearing has remained constant since then.

In five additional cases the hearing fluctuated in one ear or in both ears up to 2½ years after the disease. Three of these cases had had Meningococcal meningitis and two Haemophilus influenzae meningitis.

To conclude, all children who have had meningitis must be checked with audiograms after recovery. The hearing tests

should be repeated half a year and one year after the disease in order to reveal cases with delayed hearing loss.

If a hearing loss is observed soon after the disease, the patient must be controlled repeatedly with audiometric tests, and a hearing aid should not be fitted until the hearing has stabilized.

Tests That Never Should Have Been Ordered

Darrel L. Teter
Denver, Co.

The purpose of this paper is to alert the professions involved in providing tests of the auditory system as to problems the author sees in his daily activities as a working audiologist. The paper attempted to point out that in recent years the audiometric tests battery should have changed and should have allowed for more efficient evaluation of the patient with less time and less cost expenditures. This major change has been attributed to the influence of impedance audiometry and the amount of information it can yield relative to conductive components, cochlear hearing loss, and retrocochlear hearing loss. The author attempted to point out that we have failed to design our test batteries to include the tests that return the most information and to exclude those standard tests of several years ago which do not yield any additional information, and cost the audiologist and otologist time and energy and the patient money.

Specifically, the use of routine standing test batteries that include SISI Audiometry, SAL Audiometry, PB Rollover, and or such tests as Bone Conducted Speech and Bekesy Audiometry. Emphasis was placed upon a logical review of our standard test batteries, the time necessitated by those batteries and the logic of including tests that yield little information relative to the patient's auditory status.

The author wished to express a desire that we should carefully review our tests, the cost incurred by the patient, and the educational programs designed to equip an individual to provide quality, audiometric services at reasonable fees. The presentation was made orally and no written paper is available.

Pitfalls in Pediatric Audiologic Evaluation

Irving Shapiro
Los Angeles County Harbor
UCLA Medical Center

It has been suggested that the fitting of hearing aids to infants with sensorineural hearing loss prior to eight months of age may result in the remission of the hearing loss and lead to normal hearing. If the application of hearing aids is delayed beyond eight months of age, no such remission is observed.

The purpose of this paper was to report on the progression of minimal response levels of normal hearing infants; describe three infants who were initially diagnosed as having sensorineural

(Continued on page 5)

Abstracts . . .

(Continued from page 4)

hearing loss who later demonstrated normal hearing; and to discuss these findings as possible causes for the misunderstanding of the effect hearing aids have on sensorineural hearing loss.

The results of the study confirmed that normal-hearing infants respond to auditory stimuli at greater than adult norms and regular reductions in response level are seen as a function of developmental age.

It was also shown that infants with misdiagnosed conductive hearing loss, and normal-hearing "non-responders" who are developmentally delayed, may give erroneous impressions of the effectiveness of amplification in sensorineural hearing loss.

It is felt that the conclusion that sensorineural hearing loss can be resolved with the use of hearing aids is based upon the misinterpretation of normal hearing response levels in early infancy and the lack of adequate testing to rule out middle ear involvement.

Measurement of Central Auditory Processing Skills

Gerald Miltenberger

Barbara Corbin

John Cobb

Gerald Dawson

Harvey Bunce III

University of Texas

Medical Branch

Galveston, Tx

One hundred subjects between the ages of six and nine years were included in this study. The subjects were from three cultural backgrounds: 1) Anglo-American, 2) Mexican-American and, 3) Black-American. In all, five central auditory processing (CAP) tests were administered to each subject. Three of the tests, as described by Willeford (1976) consisted of 1) a dichotic listening task involving sentences of related content, 2) identification of monosyllabic words which have been sent through an electronic filter which is set to pass only those frequencies below 500 Hz, with a rejection characteristic of 18 dB per octave for those frequencies above 500 Hz, and 3) binaural identification of spondaic words with the low band-pass segment (500-700 Hz) of the word presented to one ear while the other ear is simultaneously presented with the high band-pass segment (1900-2100 Hz) of the same word. The fourth test in the battery was a time compressed speech task as described by Beasley et al. (1976) wherein the Word Intelligibility by Picture Identification (WIPI) test is utilized. As in the study by Beasley, the words presented to our subjects were time-compressed to 60% of original time. The final CAP test included in the battery for this study consisted of a shortened form of the original Staggered Spondaic Word (SSW) test, developed by Katz, Brunt (1972). Young (1977) reported on the utilization of the SSW test with learning disabled children wherein the stimulus items were reduced forty to twenty.

The major purpose of the study was to determine the degree to which any one of the five CAP

tests might be predictive of any one of the remaining tests. The highest correlation between any two tests was less than .5, indicating that no test is able to explain more than 25% of the variability in any other test. Therefore, it is recommended that in the assessment of central auditory processing skills of children that, at least, the five CAP tests described in this study be utilized.

The Reliability of the SSI in Hearing Aid Evaluations

R. D. Madory

T. H. Townsend

Hearing Clinic

Central Michigan University

The reliability of the Synthetic Sentence Identification test for purposes of evaluating hearing aids of the same category on sensorineurally impaired listeners was examined. Each of ten subjects was tested on two occasions with four different post-audicular aids at five message-to-competition ratios (MCRs). Data averaged across MCRs were analyzed by calculating the correlation coefficient, which was $r = 0.75$. Also, the standard deviation (S.D.) of the test-retest differences was found to be 7.8%. At the MCR (-10) alone it was 16.2%. When considering differences in scores among aids of two S.D.s as significant, in no instance was significance achieved for the data averaged across MCRs, and for only one subject was an aid eliminated across test and retest sessions at MCR = -10. The "acoustic windows" in the competition were regarded as partially responsible for the lack of reliability of the procedure; a multitalker babble may improve the repeatability of the test. Subjectively, based on subjects' impressions, the procedure was complimented.

The Effects of Continuous V. Pulsed Signals on Acoustic Reflex Decay

Gail Harsch

David Klodd

Kim McCracken

Steven Horwitz

St. Lukes Med. Center.

Chicago, Ill.

Previous studies have noted that acoustic reflex decay to a continuous pure tone is frequency dependent. In normal hearing subjects, little if any decay is present at 500 or 1000 Hz as compared to considerably greater amounts for 2000 and 4000 Hz tones. However, less information is available about reflex decay to pulsed pure tones. The investigation of Blood (1976) reported significantly greater contralateral reflex decay to continuous 2000 and 4000 Hz tones as compared to a pulsed signal with a 1 sec. duration and a 50% duty cycle. The purpose of this investigation was to determine if the contralateral and ipsilateral threshold and decay properties of the acoustic reflex were similar for continuous and pulsed tones.

Ten young normal hearing individuals with normal otoscopic examinations and normal tympanograms served as subjects. Acoustic reflex measurements were also made on a patient with a confirmed acoustic neuroma.

Acoustic impedance measurements were performed on a Grason Stadler 1723 Middle Ear Analyzer and an Amplaid 702 Acoustic Impedance Meter. The Amplaid 702 provides a continuous tone for both contralateral and ipsilateral modes. On the Grason-Stadler 1723, a continuous signal is available only in the contralateral mode. A pulsed signal (46 msec on, 64 msec off) may be selected for either the contralateral or ipsilateral mode. Acoustic reflex thresholds and decay measurements (at 500, 1000, 2000, and 4000 Hz) were obtained for all five reflex modes on the two instruments.

In the normal hearing subjects, acoustic reflex thresholds were small, with individual values usually within one 5 dB step. Acoustic reflex decay measurements were not always similar for the 5 reflex modes, however. There was no significant difference in contralateral reflex decay at any frequency for continuous tones delivered on the Amplaid 702 or the G.S.-1723. Comparing the contralateral continuous and contralateral pulsed signal on the G.S.-1723 there was no significant difference at 500 or 1000 Hz, but at 2000 and 4000 Hz contralateral continuous decay was significantly greater. At all frequencies, contralateral continuous decay on the Amplaid 702 was significantly greater than contralateral pulsed decay obtained on the G.S.-1723. Finally, ipsilateral continuous reflex decay on the Amplaid 702 was also significantly greater than ipsilateral pulsed decay on the G.S.-1723 for all four frequencies. In general, our normal hearing subjects often showed greater than 50% reflex decay to a continuous tone but little or no decay to a pulsed tone at 2000 and 4000 Hz.

We also observed the lack of acoustic reflex decay to a pulsed signal in a patient with a left sided acoustic neuroma. In this patient, with contralateral continuous stimulation of the left ear on the Amplaid 702 and G.S.-1723, there was greater than 50% reflex decay at 500 Hz, and 100% decay at 1000 and 2000 Hz. However, at these same frequencies there was no reflex decay to a pulsed signal in testing contralateral and ipsilateral reflex decay on the G.S.-1723. Ipsilateral continuous decay on the Amplaid 702 produced an increase in compliance (which we interpret as an artifact) and hence decay measurements could not be analyzed. In view of these data, when interpreting acoustic reflex decay measurements, the audiologist and physician must be cognizant that pulsed and continuous reflex activating signals do not yield the same results.

Effects of Probe-Ear Canal Pressure and Seal on Acoustic Reflex Magnitude

Roger A. Ruth

Debara L. Tucci

Ernest R. Nilo

University of Virginia

Medical Center

Charlottesville, Va.

Measurement of AR growth has recently been offered as a means

of assessment of seventh cranial nerve function in patients with Bell's palsy. These procedures have proven more sensitive to efferent reflex pathology than the mere observation of presence or absence of the AR or measurement of its absolute threshold level. The apparent superior sensitivity of AR growth in assessment of neuromuscular disorder raises the possibility that the same measure may be more easily influenced by subtle changes in the status of the middle ear or the integrity of the probe seal. Thus while accuracy of AR threshold is apparently unaffected by these manipulations, this may not be the case with measurement of reflex growth and other dimensions of the AR.

The present study was designed to determine the influence of relatively small pressure changes in the external ear canal on measures of both threshold and growth of the AR. In addition, the effects of a non-sealed probe tip on these same reflex parameters were studied.

Acoustic reflex thresholds (500, 1000, 2000, 4000 Hz and WBN) and growth function (4, 8, 12, 16, 20 dB re: AR threshold for 500 Hz only) were measured in one ear for each of 20 normal hearing individuals. Initial data were obtained at the point of maximum compliance, and then at the following pressures (in random order) relative to this point: -120, -60, +60, +120 mm H₂O. These same parameters were studied in 10 of the subjects following disruption of the probe seal.

Acoustic reflex thresholds for the tonal stimuli were found to cluster around 84 dB HL when measured at the point of maximum compliance, whereas average reflex threshold for the noise stimulus was 19 dB lower. For the most part, as ear canal pressure was increased or decreased relative to maximum compliance, reflexes were seen to vary similarly, demonstrating a small but systematic increase in AR threshold. Loading of the tympanic membrane by means of pressure variations had no significant effect on the relative difference between pure tone and noise AR thresholds. Regardless of the nature of the reflex eliciting stimulus, absence of an air tight seal had little consequence on threshold of the reflex.

Analysis of reflex amplitudes as a function of stimulus intensity revealed a significant truncation of the growth pattern measured during the application of a relatively mild positive or negative canal pressure. As expected, the greatest depression of AR magnitude occurred in the presence of plus or minus 120 mm H₂O canal pressure. In light of the relatively minor reflex threshold shift produced by these same

pressures the growth functions appear to be disproportionately reduced. For example, a positive pressure of 120 mm H₂O produced a five dB mean threshold increase and a corresponding 80% reduction in relative reflex magnitude at plus 20 dB.

The reflex growth patterns generated at static pressure values of plus and minus 60 mm H₂O were severely truncated. The no seal condition exhibits a reflex magnitude pattern which initially is parallel to that obtained at the point of maximum compliance but which diverges and tends to approach saturation at higher stimulus levels.

These findings indicate that caution should be exercised during the measurement of reflex growth to insure both proper maintenance of desired canal pressure and sufficient canal-probe coupling.

An Investigation of Blooming in AGC and Peak-Clipping Hearing Aids

William G. Ely

James R. Curran

Anthony J. Becker

Maico hearing Instruments

Mpls., Minn.

The phenomenon of "blooming" in the response of a hearing aid has recently begun to attract attention in the literature. No one has yet offered a precise definition of blooming in hearing aids, but it appears that a consensus understanding has surfaced. It suggests that blooming appears in the low frequencies, i.e., as the input signal increases in intensity, a greater amount of amplification occurs in the low frequencies in relation to amplification at higher frequencies. Non-blooming aids maintain a constant frequency response shape at all levels of input, from 50 dB to 90 dB SPL. See illustration below.

This study investigated the phenomenon of blooming, using measurement techniques designed to identify its cause, and its presence or absence in various hearing aids. It has been suggested that blooming appears in peak clipping aids and output compression aids, but not in input compression hearing aids. Therefore, one peak clipping aid, two output compression aids, two input compression aids, and one combination input/output compression aid, with approximately similar gain and output values were evaluated for signs of blooming.

Measurements were performed using a Bruel and Kjaer 1/2 inch condenser microphone, 2607 measuring amplifier, and 2010 heterodyne analyzer. A Bruel and Kjaer 1901 tracking frequency

Inside every large problem is a small problem struggling to get out.

Minutes of the American Auditory Society

San Francisco, California
Date: November 16, 1978
Place: Conrad Hilton Hotel
Time: 7:00 p.m. to 11:20 p.m.
Members Present: Dave Dolowitz, Marion Downs, Bruce Graham, Earl Harford, J. Donald Harris, Gil Herer, Norma Hopkinson, Susanne Kos, Sam Lybarger, Ross Roeser, Hiroshi Shimizu, F. Blair Simmons, W. Dix Ward, Laura Ann Wilber.
Invited Guest: James Jerger
Members Absent: James Benitez, Leo Doerfler, Fred Linthicum, Merle Lawrence, Geary McCandless.

1) President Simmons opened the meeting at 7:05 p.m.

2) The minutes of the 1977 Executive Committee meeting in Miami, Florida were presented and discussed. There were no revisions.

3) The income and disbursement statement for the period January 1 through October 31, 1978 were presented and discussed.

4) A list of 68 persons who had submitted complete applications for membership during 1978 was presented. The list included applicants' names, highest degree held, city and state of residence, and the names of the two members sponsoring the applicant. There being no objections, all 68 applicants were approved for membership. The names of those accepted as members will be published in the January issue of Corti's Organ.

A list of 15 individuals with incomplete applications was reviewed. Additional sponsors were needed for 14 of the 15 applicants. Members of the Executive Committee identified six of the individuals pending membership and offered to support their applications. These six new members will be added to the 68 names to be published in the January issue of Corti's Organ.

The names of any applicants with completed applications before January 1, 1979 will be sent to the Executive Committee by mail for approval.

5) Blair Simmons was selected for program chairman for the 1979 annual meeting to be held in Dallas in September in conjunction with the American Academy of Otolaryngology.

After discussion, the 1980 meeting location was chosen to be Los Angeles, in November in conjunction with the Fall meeting of the Acoustical Society of America.

6) The name of an individual was submitted for the 1979 Carhart Memorial Award. The Secretary/Treasurer will contact him and, if he accepts, the Society membership will be informed through Corti's Organ.

7) Jim Jerger arrived and presented information regarding a movement that is being made to form an Institute on Communicative Disorders. A committee of about 25 persons has had two separate meetings this year to work out details. Dr. Jerger was appointed to be a liaison between various groups, such as AAS. It was stated that the purpose of his appearance at the meeting was to request support, in principle, for this concept.

After considerable discussion a motion to write a letter of support

was tabled, provided that Executive Committee members receive a fact sheet that is being prepared by members of this movement and a copy of the motion by December 19, 1978; each member responds individually, providing his/her thoughts on the issue, to the Secretary/Treasurer by January 7, 1979; and responses of each member be sent to all members of the Executive Committee before February 1, 1979. The final vote will be taken by March 15, 1979.

8) Laura Wilber was selected as President Elect 1979.

9) Susanne Kos was selected as Assistant Secretary.

10) Dix Ward was selected to be on the nominating committee to replace the seven members of the Executive Committee up for election. The seven members are: James Benitez, Leo Doerfler, David Dolowitz, Gil Herer, Norma Hopkinson, Hiroshi Shimizu, Laura Wilber.

11) Ross Roeser was reappointed as Secretary/Treasurer for 1980.

12) At the 1977 meeting of the Executive Committee, a subcommittee was formed to explore the possibility of having AAS sponsor a national meeting. Several alternatives were presented at the current session and it was decided to limit the alternatives available for the Executive Committee to discuss in September 1979. Bruce Graham and Norma Hopkinson are co-chairmen of the committee.

13) Marion Downs and Ross Roeser reported on Corti's Organ. It was decided to continue publishing one promotional issue per year, with the exception that it be the April issue which has the directory of the membership for the year.

It was pointed out that there is a need for an advertising manager for Corti's Organ. Since there was no immediate solution to identifying such a person, it was decided to place an announcement in the January issue to solicit a qualified member to fill this need.

The remaining time was spent discussing the Journal of the American Auditory Society. No specific motions or policies were formally adopted.

The meeting adjourned at 11:20 p.m.

Date: November 17, 1978

Place: Sir Frances Drake Hotel

Time: 8:30 a.m. to 9:45 a.m.

There was no change in the members present or absent from the November 16th meeting.

1) President Simmons called the meeting to order at 8:30 a.m.

2) Discussion of the Journal of the American Auditory Society continued from the November 16th meeting.

Dr. Harris expressed public appreciation to the following Section Editors:

Dr. Phillip Bellefleur
Dr. William Cooper
Professor Marion Downs
Dr. Allan Goodman
Dr. A. Bruce Graham
Dr. Norma Hopkinson

AMERICAN AUDITORY SOCIETY INCOME AND DISBURSEMENT STATEMENT For Period January 1, 1978 - October 31, 1978			
	Income	Disbursements	
Cash on Hand Checking Account 1-1-78			\$ 1,086.44
Cash on Hand Savings Account 1-1-78			12,392.95
Membership Dues	\$18,435.07		
JAAS Allowance	2,000.00		
Interest on Savings Account	295.85		
Sale of Advertising-Corti's Organ	985.00		
Convention Registration	136.00		
			21,851.92
TOTAL INCOME			\$35,331.31
Equipment		\$ 132.12	
Supplies		256.07	
Postage-Office		511.48

Dr. Robert W. Keith
Dr. George Lynn
Dr. Thomas Porter
Dr. William Rintelmann
Dr. Jay Sanders
Dr. Hiroshi Shimizu
Dr. John Sinclair
Dr. Richard Sweetman
Dr. W. Dixon Ward

The following motion was made:
"Dr. J. Donald Harris continue as the editor of the Journal of the American Auditory Society and that the membership offer support and take individual responsibility for the journal and that an otolaryngology oriented associate editor be appointed" Passed.

A second motion was made:
"Blair Simmons be made a member of the Editorial Policy Board" Passed.

Several options were presented to stimulate the submission of manuscripts to the Journal. Among these suggestions were that:

A) The Journal publish a review of audiology.

B) To publish an occasional tutorial paper or a review of a particular topic.

The following motion was made:

To "Invite members of the Executive committee or other interested persons to nominate articles in foreign language journals to appear in the Journal of the American Auditory Society and that the criterion for selection should be that the article appeal to at least two groups within AAS." Passed.

3) The status of the life membership category was discussed and possible ways of altering the By-Laws were suggested. However, no formal motions were made.

The following motion was however made:

"In view of his service on the Executive Committee, David Dolowitz be accepted to Life Membership." Passed.

The meeting adjourned at 9:45 a.m.

Respectfully Submitted,
Ross J. Roeser, Ph.D.
Secretary/Treasurer

Katz Presents Workshops

The University of Wyoming, Department of Speech Pathology and Audiology will be hosting a three day workshop on the SSW and CES (Staggered Spondaic Word and Competing Environmental Sound) tests on May 3, 4 and 5, 1979. The workshop

will be presented by Dr. Jack Katz.

For information and registration contact: Ben J. Koperski M.A., Department of Speech Pathology/Audiology, University of Wyoming, PO Box 3311 30 Ross Hall, Laramie, WY 82071. (307) 766-6426.

CHABA Covers Infant Testing

In an unusual angling of topics for the Committee on Hearing and Bioacoustics and Biomechanics (CHABA), almost an entire morning of its November meeting was devoted to infant hearing testing. The meeting was held at the beautiful new Boy's Town Institute in Omaha. Brain Stem Evoked Response Audiometry for infants was covered by Hallowell Davis, Donald Teas and Robert Galambos. Davis described his identification of thresholds in four frequencies in a one hour testing session. Teas discussed the abnormal latencies in infants and their gradual emergence to normal values. Galambos also described the emergence of normal latency periods in infants, stating that by one year the latency reaches adult values.

George Mencher described the application of a High Risk Register for identifying deafness. AAS's president Blair Simmons reported on the Crib-O-Gram in detecting deafness in the newborn nursery.

Other outstanding papers were given by two past AAS presidents, Aram Glorig and Dix Ward. Glorig gave a classic review of the literature on the effects of noise on man. He stated that the studies on physiological effects of noise exposure are contradictory and difficult to evaluate. On the whole the studies are inconclusive. Dix Ward discussed impulse and impact noise, which are two different categories of exposure. The effect of impulse noise can be measured by total energy, he said.

Other significant papers on noise were given by such people as Karl Kryter, who reported on the Freiburg conference, where the conclusion was that the study of health effects of noise exposure is a primary research need. David Lim described experiments with infra-sound (1 to 28 Hz). He showed that infra sound can cause damage to the cochlea, particularly at 170 dB.

Stephen Gray contradicted reports that noise levels cause Birth Defects, Low Birth Weight and Lowered fertility. He stated that there is no reason to suppose that noise has a direct effect on the fetus. Animal research is the only method of investigating this subject.

multiplier was used to synthesize tape playback signals with the 2307 servo controlled level recorder.

All measurements were made in a seven by five foot walk-in anechoic chamber. KEMAR was centered in the chamber 1 meter from the speaker. The substitution method was used in obtaining responses from the hearing aids, where KEMAR is replaced by a reference microphone located at the center of the head on a line between KEMAR's ears. A tape recording is made of a swept frequency pure tone signal necessary to produce a flat spectrum at the reference microphone with KEMAR removed, thereby holding the input signal constant across frequency at the plane of KEMAR's ears. With KEMAR re-positioned, the tape is played through the amplifier and speaker, and the curves obtained show the response of the aid, including the effect of hearing aid microphone position, the ear mold, ear canal resonance, plus pinna, head, and body baffle. A standard acrylic, well sealed mold was used in conjunction with the new, large KEMAR ear. After measurements were completed using a swept pure tone signal as input, a broad band, flat spectrum white noise was used to analyze the blooming behavior of the instruments when a continuous level, broad band signal was employed as input.

Results with the pure tone signal input showed that blooming can appear to be present in peak clipping, output compression, input compression, and combination input/output compression hearing aids. The presence of blooming in compression aids is an artifact of the swept pure tone measurement procedure. Since

the commonly used test procedures utilize a slowly swept or fixed frequency pure tone input, each higher frequency is measured at succeeding intervals in time. Under these conditions, compression aids will act as time varying amplifiers having different gains at different distances in time due to the unique interaction of input level and the AGC amplifying characteristics. The threshold of compression in most AGC circuits is frequency dependent, often being higher at low frequencies and lower at the higher frequencies. Therefore, if the amplitude of the 500 Hz input signal is held constant, and the level is below the threshold of compression, no automatic reduction in gain will occur. At 2000 Hz, where the gain is higher, the same input level may fall above the threshold of compression and an automatic reduction of gain will occur for that frequency. The net result, in a family of frequency responses developed using pure tones, is that the aid will appear to have more gain in the low frequencies as compared to the high frequencies as input levels are successively increased. In addition, the amount of blooming can be exaggerated by the presence of harmonic distortion products, particularly in instruments utilizing peak clipping output limiting.

When a wide spectrum random noise was used as the input signal, it was found that only the peak clipping instruments showed evidence of blooming, and neither the output compression aids, the input compression aids, nor the combination input/output compression aid gave evidence of blooming under this measurement condition. It can be

shown that whenever the level of a broad band noise becomes high enough to exceed the threshold of compression, the instantaneous frequency response of a compression aid will remain constant over the range of applicable input levels. It was concluded on the basis of these measurements, that the most accurate description of an aid's performance with reference to blooming, is provided by results obtained using broad band input signals, rather than swept or fixed frequency pure tone measurement techniques.

A Comparison of Custom In-The-Ear Hearing Aids

M. Richard Navarro
and Peter B. Ivory
McFarland Clinic
Ames, Iowa

Custom in-the-ear (ITE) hearing aids constitute approximately 35% of the annual hearing aid market. Many audiologists are reluctant to recommend such units for a variety of reasons. For example, it is not feasible to have four or five custom units built for each patient in order to carry out a comparative hearing aid evaluation. Furthermore, many audiologists are still under the impression that custom ITE units are appropriate only for those individuals with mild hearing loss. The situation is compounded by the number of custom instruments available and by claims made by differing manufacturers. The stated advantages of the ITE include: a) Advantages of the pinna; b) Cosmetic Appeal and; c) Custom-fitted amplification. The absence of a standardized fitting approach as well as the number of manufacturers posed

intriguing questions regarding the nature of commercially available custom-fitted amplification.

The purpose of this study was:

- 1) To compare custom ITE hearing aids provided by different manufacturers;
- 2) To utilize custom ITE in the fitting of moderate/severe hearing loss.
- 3) To compare binaural versus monaural ITE fittings;
- 4) To identify possible subjective benefits of the ITE hearing aid over more conventional behind-the-ear hearing aids.

Standard audiometric data on one 30 year old male patient who possessed a bilateral moderate to severe sensorineural hearing loss was provided to five hearing aid manufacturers. Each manufacturer provided a pair of custom all ITE hearing aids (one for each ear). All but one of the manufac-

identification of one hearing aid manufacturer which provided the best performance for this patient. In fact, the best hearing aid provided up to 60 dB of in-the-ear gain for a 3000 Hertz warble tone. This gain was 30-40 dB greater than any other hearing aid and may reflect the combined effect of ear canal resonance and the hearing aid system. Both the warble tone threshold and the acoustic reflex thresholds agreed in identifying one manufacturer's hearing aid as the best for this patient. The total summed ranks for all measures as shown in Table 1 reflects this division of the hearing aids tried.

Subjective comments on each unit revealed substantial differences between hearing aids in

	Audiotone	Dahlberg	Hearing Aid Ranking Maico	Starkey	Zenith
Discrim. Quiet	48.5	68.5*	55.0	40.0	58.0
Discrim. Noise	67.5*	37.0	59.5	67.5*	42.5
Warble Tone	51.5	55.0	50.0	35.0	78.5*
Acoustic Reflexes	33.5	38.0	37.0	20.5	51.0*
Total	201.0	198.5	201.5	163.0	230.0*

* = hearing aid of choice using this measure.

turers was told that the hearing aids would be evaluated in the Center for Communicative Disorders using a battery of tests. Each manufacturer was asked to build binaural instruments and to provide the same data they normally would to their own hearing aid dealers.

Each hearing aid was submitted to the following clinical test battery in an attempt to evaluate the differences between hearing aids: sound field acoustic stapedial reflex measures with warble tone stimulus (monaural only); sound field warble tone thresholds; speech discrimination articulation curves, plotted from ten to sixty decibels sensation level in quiet and noise (S/N=0). Before any testing began, however, the patient wore each hearing aid for a period from one week to four months. This forced the patient to have considerable experience with each unit. At the end of the test sequence, he was asked to provide subjective comments on each unit.

The amount of data generated required that a ranking procedure be used to compare the performance of each hearing aid for each test. A rank of 1 was assigned to each hearing aid which provided the poorest performance for that measure while a rank of five was assigned to each hearing aid which provided the best performance. The ranks for each condition were then summed for each hearing aid to derive a composite ranking for that condition as well as for all conditions.

In general, the speech discrimination measures in quiet were not particularly revealing as they were too similar across hearing aids while the discrimination scores in noise were too variable to allow the selection of one hearing aid as the best hearing aid for this patient. The warble tone threshold and acoustic reflex threshold data, however, allowed

term of sound quality, accessibility to volume controls, and telephone switches, elimination of wind noise, and usefulness of the telephone coil.

Table 1. Composite summary of rankings for five hearing aids based on four clinical measures.

This study evaluated the efficiency of five pairs of custom in-the-ear hearing aids with a patient who possessed a moderate to severe sensorineural hearing loss. The results of four clinical measures of hearing aid usefulness revealed that in-the-ear instruments can be used with good success with a moderate to severe hearing loss. Most importantly, however, the results demonstrated clear differences between hearing aids which were custom fit to a given hearing loss. The most significant conclusions of these data is that one cannot assume that the best amplification possible has been fit just because the unit has been custom built. Each hearing aid demonstrated benefit to this patient under one condition or another. Because of this variability: it is a questionable assumption to state that any given hearing aid is an appropriate fitting unless it has been submitted to a variety of tests. In all likelihood, this patient may have answered affirmatively to the question "Does the hearing aid help you?" for each hearing aid. Yet, these results clearly show that "help" assumes different proportions with different hearing aids. Any given patient will never know how good he might hear with a different hearing aid unless he tries that hearing aid.

It must be pointed out that the actual ranking of any given hearing aid for this one patient cannot be generalized to the population at large. With this in mind, we stress that the low performance with this patient for any given hearing aid does not imply that any given manufactur-

er offers a poor quality instrument. It merely points out that substantial differences in hearing aid/ear interactions do exist and that the word "custom" when used with hearing aids does not mean "best."

Treating Tinnitus With Electromyographic Feedback

Thomas E. Borton

Walter H. Moore

Sandra R. Clark

Auburn University

Auburn, Alabama

Our purpose was to study the relationship between EMG activity at the frontalis muscle site, and behavioral severity ratings of tinnitus and annoyance. More specifically, our intent was to examine the covariation of behavioral severity ratings with decreases, as well as increases in EMG activity, using biofeedback procedures in a single adult female subject with intractable tinnitus. A second purpose was to assess the generalization both between and within sessions of treatment effects.

The subject in this investigation was a 60-year-old female with a unilateral hearing loss. The hearing impairment was of sudden onset and was reportedly accompanied by severe ringing tinnitus.

Tinnitus and Annoyance Ratings. Two ten segment scales were constructed to permit the subject to rate first, the severity of her tinnitus, and second, the degree to which she was annoyed by it. The subject recorded tinnitus and annoyance magnitude ratings throughout the course of the investigation upon awakening, and each hour thereafter until bedtime, as well as before and after each session.

Psychoacoustic Measurements. Once during each phase of the investigation, two aspects of the subjects' tinnitus were measured. First, the pitch of her tinnitus was estimated. Second, the stimulus most similar to her tinnitus was presented to the normal ear at a minimal intensity level. A loudness balancing technique was utilized which required the subject to match the "loudness" of the stimulus in her normal ear to the "loudness" of the tinnitus in her impaired ear.

A Grass ink-writing polygraph was used to simultaneously record three types of data: 1) the raw EMG signal, 2) the average integrated signal, and 3) the cumulative integrated activity as a function of time.

Miniature electrodes were applied over the frontalis muscle sites using standard procedures. The subject was seated in a comfortable chair in a sound attenuated chamber out of view of the instrumentation.

Each session was divided into five-minute segments with about three minutes between segments. Each session was comprised of from five to seven five-minute segments, and was separated by at least 24 hours.

Phases of the investigation were designated as baseline, treatment, or follow-up. To evaluate generalization between and within treatment sessions, we began and ended each session with a five-minute segment of no feedback. During treatment segments, the subject's task was to keep the broad band noise associated with EMG activity off

During following-up and baseline segments, no feedback was provided to the subject with regard to her EMG activity. Feedback criteria were systematically increased or decreased using a progressive shaping procedure.

The data were analyzed using a "double reversal" type of signal subject experimental design. Contingent auditory feedback resulted in a gradual and consistent decrease in frontalis EMG activity. This decrease became relatively stable as treatment progressed, when compared to baseline levels. The high levels of EMG activity during pre- and post-session baseline segments for the first three treatment sessions stood in contrast to those in later sessions of the first treatment phase. Further highlighting the effects of auditory feedback. This generalization of decreased EMG levels between and within sessions clearly demonstrated that the subject could control frontalis EMG activity in the absence of auditory feedback after she had sufficient training. Such findings were anticipated and were not new.

However, analysis of the behavioral severity ratings of tinnitus and annoyance revealed that post-session ratings were always less than pre-session ratings during the baseline phase, despite the absence of auditory feedback. A similar pattern of severity ratings occurred during the first treatment phase. Further, no substantial difference in absolute magnitude was observed between tinnitus and annoyance severity ratings made during the baseline phase and those made during the initial treatment phase. In fact, the lowest severity ratings for both tinnitus and annoyance occurred during the first baseline session in the presence of the highest EMG activity levels.

Psychoacoustic measurements of the subject's tinnitus made during the first baseline and treatment phases were compared. No predictable changes were noted. We held frequent conversations with the subject throughout the course of the investigation. About half-way through the first treatment phase, she began to report a change in her "coping strategies." She also reported such feeling states as "establishing a kind of communication union; a feeling of security; completion; happiness; peace; and joy." At one point, she reported feeling that she was "in control."

A unique feature of this investigation was the introduction of a reversal phase. That is, an attempt was made to actually increase the subject's frontalis EMG activity by presenting broad band noise until EMG levels were above a pre-selected microvolt level. During this phase, auditory feedback resulted in substantially increased EMG activity levels. During the first session of this phase, post-session tinnitus and annoyance severity ratings were, for the first time, greater than pre-session ratings. However, this trend did not continue. In fact, a pattern indistinguishable from that seen during the baseline and first treatment phase reappeared. No essential change in the subject's psychoacoustic description of tinnitus was noted. Finally, this reversal phase occasioned reports from the subject of such

feeling states as "... a thought track rather than an experience not euphoria." These comments stood in contrast to those made during treatment phases designed to decrease the subject's EMG activity levels.

Following the reversal phase of the investigation, a baseline phase was re-introduced. During this period, EMG activity patterns became somewhat erratic. They were typical of those seen during extinction procedures, and they likely resulted from confusion of the subject's internal response criteria. Behavioral severity ratings maintained their usual level and pattern, and no change in psychoacoustic judgements of tinnitus were noted.

Subsequent to this baseline phase, a second and final treatment phase was introduced. An immediate decrease in frontalis EMG activity was observed as soon as auditory feedback was re-introduced, accompanied by a change in behavioral rating patterns or in psychoacoustic judgements of tinnitus.

Finally, follow-up baseline data were collected at three and six week intervals after the last treatment session. All of the findings during this follow-up period were similar to those observed during the final treatment phase.

In summary, our procedures were effective in manipulating EMG activity, but the resulting changes in EMG levels were not systematically related to the subject's severity ratings of tinnitus and annoyance.

Second, the psychoacoustic judgements made by this subject showed no predictable change from one phase of the investigation to the next. For a number of reasons, we believe these kinds of measurements may be inappropriate for assessing treatment effects when treatment is directed toward the modification of psychological reactions to tinnitus.

Third, while some might be intrigued by the notion that reduced EMG activity promoted reduced anxiety, increased blood flow to the cochlea and, therefore, reduces the severity of tinnitus, this idea derives no support whatever from the results of this investigation.

Finally, despite the lack of a systematic relationship between EMG activity and behavioral ratings of tinnitus and annoyance, and despite a meaningful change in the subject's psychoacoustic description of her tinnitus across the phases of this investigation, she did report the development of psychological strategies which were associated with both increases and decreases in EMG activity. Given the controls of this investigation, the outcome observed might best be explained as a "placebo effect." Nevertheless, it is logical to assume the presence of some independent variables, which are empirical in nature and are common to the and possibly other methods of treating tinnitus, which could be isolated and controlled experimentally. These variables should be identified. Until they are, the indiscriminate use of EMG biofeedback procedures for the routine clinical management of persons who suffer from tinnitus should be discouraged.

Hearing Loss Patterns
in Sick Newborns
Blair Simmons
Stanford Univ. Med. Center
Stanford, Calif.

Graduates of Intensive Care nurseries have an impressively high incidence of deafness, 1:62 live discharges. We deafened 22 of these babies before discharge by using an automated hearing screening system. Their medical records and the records of 70 control babies were reviewed and compared for probable risk factors. In general, the hearing loss babies seemed sicker than the controls. Their hospital stay was twice as long as the control group. Anoxia, as reflected by low APGAR scores, was 7.6 times more common in the hearing loss group. Foetal distress, complicated deliveries, and hyperbilirubinemia seem to be key ingredients in most deafness. Anoxia later on, as reflected by the diagnosis of respiratory distress syndrome, made little difference. Uncomplicated prematurity, or the use of ototoxic antibiotics are irrelevant features.

The results of this on-going study testify strongly in favor of hearing screening in ICU Nurseries.

Auditory Fusion in Infants
A Behavioral Means of
Assessing
One Aspect of Central
Auditory Function

Wesley R. Wilson
and
Allan Diefendorf
University of Washington
Seattle, Wash.

Existing behavioral procedures used in the assessment of central auditory function have not been effective in testing children under five to six years of age. In fact recent data showing the wide dispersion of scores obtained on children under 10 years of age suggest difficulties in interpretation for children between five and 10 years of age. Among the problems in application of the existing procedures with children are the dependence on language as well as the memory load imposed by the measurement task. This paper described a procedure which is not dependent on language as the response mode and which minimizes and controls memory load.

Fusion of two segments of a speech sound presented dichotically into a single percept requires fusion of the dichotic parts in the central auditory system. The task involves teaching infants to respond when they hear a specific speech sound and not to respond to any other signal. The response used is a head turn coupled with visual reinforcement for correct responses.

The signals used are computer generated speech tokens as well as computer generated formant segments of the same speech-sound tokens. The formant segments are selected so as to allow correct identification of the speech sound when they are combined but not provide enough information to be recognizable

when presented singly.

The infant is trained to respond to a selected speech sound under didactic presentation while not responding to other speech sounds or the single presented formants. Once the infant has demonstrated success at this level, the presentation mode shifts to both didactic and dichotic. If the infant responds correctly when the two formant components of the target speech sound are presented dichotically, he/she has demonstrated central fusion of the formant signals. Failure to respond correctly to the dichotic fusion task while successfully responding to a monaural or didactic fusion would suggest a breakdown in central fusion.

This paper reported on work completed to date on young infants and provided a video demonstration of an eight-month-old child. It was suggested that the same task could be modified to assess other aspects of central auditory function.

Behavior Changes Associated with the Resolution of Middle Ear Effusions

William P. Potsic
Roger R. Marsh
Elliot J. Gursky
Childrens Hospital
of Philadelphia
Philadelphia, Pa.

Children having middle ear effusion were judged by their parents to be less obedient and harder to control than were children who were free of middle ear effusion. When members of both groups were re-examined 6-12 weeks later, those having normal middle ears on both visits had no change on the behavioral indices. Those children who had middle ear effusion on the first evaluation showed improved behavior, as judged by parents, whether or not they had responded to treatment of the serous otitis. These data suggest that diminished auditory acuity does in fact lead to behavior changes, but that parent and child adjust to alterations in behavior and acuity in the interval between the first and second examination.

The Effect of Early Onset of Otitis Media on Educational Achievement

Virgil M. Howie, M.D.
Norma J. Jensen
James W. Flemer
Milton b. Peeling
Stanley Meigs
University of Texas
Medical Branch
Galveston, TX

Otitis media has recently been established to be more prevalent than anyone ever believed. Development of modern electronic techniques in detecting otitis media makes it important to know whether or not otitis media is needed of any great importance in terms of the child's total life potential. The following study was designed to test the effects of acute episodes of otitis media occurring in the first eighteen months of life on subsequent educational achievement. Two groups of children were collected from practices of the three participating pediatricians

comprising 72 pairs. The pairs were made on the basis of one group having zero attacks of otitis media the first eighteen months of life being observed from birth by the pediatricians and the second group having three attacks of otitis media observed in the first eighteen months of life. Each pair was matched with another from the second group by birth dates, within a six week period excluding the birth year, sex, occupation of the father, and his professional, technical skill, semi-skilled and unskilled, and by the school attended in the Huntsville school district, and the year of testing, that is, whether they were tested in the third or sixth grade. The tests used to compare the two groups of students were the SRA test or Science Research Associates Test for academic achievement. This test was chosen because all children in the Huntsville school system are given this test at sometime. Sample areas are directly related to academic subjects. The test has good reliability across school years. The test yielded values for reading, language arts, math and a composite score. Comparison of the mean along with the standard deviation and standard error reveal that the one-tailed t-test reveal that only the composite score was significantly different in favor of the students having had no episode of otitis media in the first eighteen months of life. The math approach significance but at only a 10 probability level. Language arts and reading, although the mean was apparently six months above the mean of those having three episodes of otitis media was not found to be significantly different due to the wide standard deviation. This study of patients seen in Pediatric practice from 1959 to 1963 with tests being made at the third and sixth grades in Huntsville school system simply adds one additional piece of evidence to the fact that early onset of otitis media is significant in a later school achievement.

A Review of Transneuronal Changes of the Auditory Central Nervous System as a Consequence of Auditory Defects

Robert J. Ruben
Albert Einstein
College of Medicine
Bronx, NY

During the last three decades there have been numerous investigations revealing a consistent pattern of transneuronal changes of various portions of the central auditory nervous system which have been associated with either anatomical defects in the peripheral auditory apparatus (cochlear and/or acoustic division of the VIII nerve), or with reduction of auditory stimulus to the cochlea (auditory deprivation). The changes are essentially consistent from species to species, and qualitatively similar regardless of the type of peripheral deficiency which was effected. These will be reviewed in this report.

The anatomical changes may or may not have implications in the care and habilitation of hearing

deficits in man. As will be seen from the data, certain broad characteristics of the resultant central auditory nervous system changes are known in various species. Whether or not the same changes occur in man and how they might manifest themselves is unknown. It is hoped that one effect of this review will be to provide a basis to ask critical questions in the area of human audition and neuropathology.

The data which is now available suggests certain hypotheses. These are:

1. The earlier in development of an animal that there is an anatomical loss of the inner ear and its nerve, the greater the anatomical effect will be on the central auditory pathways.

2. Anatomical loss of the inner ear and its nerve or auditory deprivation during the immediate postnatal period in the rodent and the cat will result in changes in the primary and second order auditory nuclei of the brain stem.

3. The anatomical effects of auditory deprivation in the newborn mouse are, in the main, irreversible.

There are still a large number of open questions concerning the physiological and behavioral effects of these changes. Furthermore, there is almost no data concerning the effects on the thalamus and the cortex in either the chick, the rodent, or the cat. Another area in which there is a need for more information is to correlate the developmental stage of the inner ear and the time which the auditory deficit is made with the developmental stage of the central nervous system. The mouse, for which there is a large body of data, does not develop a mature inner ear in regard to anatomy and physiology until about the second week of postnatal life. The mouse brain is likewise immature until about the 20th day of postnatal life. The inner ear in the chick, rat and the cat also mature before the central nervous system. There is a similar pattern of development in man, in that the inner ear appears to be mature, anatomically and physiologically, at birth and perhaps as early as the 7th or 8th

month of gestation, whereas the central nervous system may not be mature until after the first decade of life. Yet it is known that the physiological responses of the brain stem in man to sound appear to reach its maturity between the 12th and 18th month of age. The characteristics of these different rates of maturation and their effect on the consequence of the various auditory deficits, either due to anatomical lesions or deprivations, or the central nervous system in terms of anatomy, and ultimately, physiology and behavior.

Synopsis of Paper-Overview of Objective Hearing Tests

Derald E. Brackmann
Foundation of Otology
Los Angeles, Calif.

The importance of early identification and treatment of hearing impairment is becoming increasingly apparent. Ideally, positive identification of the degree of impairment should be made by age six months and rehabilitation with amplification begun. Newer objective audiometric tests may make this ideal practical in the clinical setting.

Early identification of hearing impairment includes the cribogram and impedance testing. If either or both of these tests indicate normal hearing, it is unlikely that hearing impairment exists. On the otherhand, any abnormality in either of these tests requires thorough evaluation including brainstem electric response audiometry.

Threshold for detection of brainstem responses to a broadband click is an indication of the hearing thresholds in the three to four kHz region. In cases of flat

Southern Audiological Society Meets

The Seventh Annual Convention of the Southern Audiological Society was held at the Monteleone Hotel in New Orleans, August 30 through Sept. 1, 1978. The program of technical and scientific papers featured Dr. Paul Guth, Dr. Michael Pollack, and Dr. Lindsay Pratt.

Officers elected for 1978-79 were President John C. Cooper (Texas), President-Elect—Carl W. Asp (Tennessee), Secretary-Treasurer—William H. Andersen (South Carolina), and Member-at-Large—Thomas O. Davidson (Tennessee).

The 1979 meeting of the society will be held in Savannah, Georgia, September 5-7, 1979.

Sentac Meets in Santa Barbara

The annual meeting of the Society for Ear, Nose and Throat Advances (SENTAC) in Children was held at the El Encanto Hotel in Santa Barbara December 8-10, 1978. The new president, pediatrician Robert Kramer announced several changes in SENTAC policy. Papers presented at this meeting will be published in the new Journal of Pediatric Otorhinolaryngology, edited by Robert Ruben, past president of SENTAC.

Almost the entire section on Audiology and Otology was devoted to the problems of early otitis media in infants, and on the measurement of hearing and auditory problems in infants and children. Some of the key papers are abstracted below.

Article Review

Developmental And
Psychoeducational Sequelae of
Chronic Otitis Media

By:

Peter W. Zinkus
Marvin L. Gottlieb
Mark Schapiro

in *Am. J. Dis. Child*-Vol 132, Nov.
1978
pp. 1100-1104

This article presents compelling evidence that severe and recurrent otitis media in early life has a long lasting effect on the language and educational development of children between the ages of 6 and 11 years. This study manages to avoid some of the problems of other studies in this field such as possible differences in intellectual or socioeconomic levels. Tests were administered and scored by persons unaware of the otitis media history of the children. Forty children (average 8.5 years) were selected from a larger group referred for comprehensive evaluation because of academic underachievement. Their scores on the Wechsler Intelligence Test for Children-Revised were compared, purely on the presence or absence of documented evidence of severe and continuing otitis media during the first three years of life. All children were from white, middle class backgrounds. Those suspect for prenatal, perinatal, or post-natal CNS injuries, as well as those with severe behavioral or emotional disorders were not included in the study. Children with visual perceptual dysfunctions were also not included, nor were those with IQ's below 85.

The following defects were observed in the 18 children with severe early otitis media at the P. 95 level of confidence when compared with the 22 non-otitis children: **Developmental** — acquisition of a 4-10 word vocabulary, ability to formulate and utilize sentences of three or more words; **Intelligence Testing** — worse on both verbal and non-verbal segments, but these overall scores were strongly influenced by subset scores dependent on auditory processing skills (mental arithmetic, auditory sequential memory, concept formation); non-verbal skills were reduced only by those tests involving auditory and language processing skills. **Academic Skills** — worse scores on word decoding and spelling skills.

The following parameters were among those not different for the two groups: **Developmental** — walking and motor skills; **Intelligence Testing** — general fund of knowledge, expressive vocabulary, pure visual processing tasks, analytical reasoning; **Academic Skills** — intelligence as related to reading level, arithmetic computation skills.

Though all children were referred for suspected academic difficulties, the actual test performance on word recognition, spelling and arithmetic were equivalent or above grade level in some cases. This occurred in 13 of the 22 otitis cases but in only 3 of the non-otitis children.

SCIENCE and Sex

As most AAS members know, the senior editor of *Corti's Organ* is an ardent advocate of the Equal Rights Amendment. Just to remind readers of the urgency of ERA I have gleaned some interesting items from recent issues of *SCIENCE* and from *Natural History*, for your edification. Did you know for example, that Broca (of Broca's area) was one of the worst of all male chauvinists? And did you ever really question why Nature in her great wisdom created two sexes as a necessary condition to evolution? *SCIENCE* did. So from the pages of these austere journals—

The Evolution of Sex. John Maynard Smith. Cambridge University Press, New York, 1978. Cloth \$21.95; paper \$6.50. Reviewed in *Science* (by Egbert G. Leigh, Jr.), 202:1274-5, 1978.

The reviewer of this book finds it pleasant, even charming, rich with interesting asides. It is a book for biologists steeped in the wonder of evolutionary processes, but for others it is fascinating for even attempting to answer the philosophical question of why there should be two sexes in most of the animal and plant kingdom, instead of one — or three? Smith demonstrates first that sex facilitates evolution, and then theorizes as to how it is maintained.

Historically, it was thought by Fisher that the only use of sex is to enable the simultaneous fixation of favorable mutations. Sex and recombination seemed to indicate a stream of favorable mutations and a genetic system organized to facilitate natural selection. But it seemed mathematically impossible to quantify the advantage of sex and how much it benefited the individual and the species.

Smith feels that the root of the problem is the "50% cost of sex": most populations spend as much effort on male as on female functions, whether in raising as many females as male offspring as in gonochores, or in spending as much effort seeking to fertilize the eggs of others as making eggs, as in hermaphrodites. A theory of anisogamy explains why sperm are so much smaller than eggs. "Why one gamete should sit and wait with the baggage while the other travels fast and light to seek her out." The sperm is the object of a competition that rarely increases the number or quality of offspring. The cost of sex is the offspring that are sacrificed by the wasted effort of this competition.

The cost of sex can be overcome, providing the genotype or the environment is changing. An illustration from Williams proposes that in trees, where many seedlings from few parents compete for a gap sufficient for one adult, a sexual parent with different offspring has as many chances as it has offspring of producing the best genotype there. An asexual parent with identical offspring has only one chance at the gap, however many seedlings it leaves there.

Smith agrees with Fisher that sex allows a mutant to be tested in many genotypes and to be selected according to its average contribution to fitness rather than

according to the fitness of the genotype where it came from. So sex does facilitate evolution. But Smith is not so certain as to what maintains it.

Smith shows that selection favors sexual species of animals. Few asexual forms are found in the tropics, where plants and animals run coevolutionary races with predators and competitors. There seems to be an advantage accruing to recombination if a gene enhancing it were closely enough linked to a new favorable recombinant to hitch a ride on it. For example, alleles increasing mutability "hitch rides" from the spread of new favorable mutants to which they are closely linked. Mutator alleles can make mistakes, but a mistake kills only one mutator, while a good mutant can spread its mutator through a population. This aspect argues for the efficacy of small selective differentials.

Well, we never said sex was easy to understand, but we're glad that someone out there is trying to figure out how it all started. We're not going to rib you about this.

Marion Downs.

Women's Brains: Stephen Jay Gould. In *Natural History*, Oct. 1978, pp. 44-50.

The science of anthropometry was used by prominent scientists in the 1800's to make devastating attacks on women's intelligence. No other than Paul Broca (1824-80) devoted untold effort to demonstrating that brain size accounted for the inferiority of women, blacks, and apes. Broca's conclusions were based on the larger brains of men in modern societies and on a supposed increase in male superiority through time. On over 400 brains at autopsy he calculated an average weight of 1,325 grams for males, 1,144 for women, or 14% difference. But this great scientist made no attempt to measure the effect of the height differences, stating that body size cannot account for the entire difference because "we know, a priori, that women are not as intelligent as men". (When modern scientists reexamine his data and correct for height, age, degenerative processes and body build, the true difference comes close to zero). But Broca used his data on women's brains to apply to other groups: blacks, poor people, criminals, children as well as women were all denigrated by the measure of brain size. "Men of the black race have brains scarcely heavier than women" stated one of Broca's disciples. This led to claims that anatomically and emotionally, both women and blacks were like white children—and that white children, by the theory of recapitulation, represented an ancestral (primitive) adult stage of human evolution.

The argument for the increasing differences between men's and women's intelligence was based on the measurements of 13 pre-historic skulls found in L'Homme Mort Cave. Broca described only 99.5 cc difference between these male and female brains as against 129.5 to 220.7 in modern days. Using these data

and Broca's other findings, one of Broca's chief disciples, Gustav Le Bon in 1879 published a vicious attack on women: "All psychologists who have studied the intelligence of women recognize today that they represent the most inferior forms of human evolution and that they are closer to children and savages than to an adult, civilized man. They excel in fickleness, inconstancy, absence of thought and logic, and incapacity to reason. . . . The day when, misunderstanding the inferior occupations which nature has given her, women leave home and take part in our battles; on this day a social revolution will begin, and everything that maintains the sacred ties of the family will disappear." (Sound familiar Phyllis Schafly?)

In 1961 at the Anthropological Society of Paris Broca won acclaim for his statement: "In general, the brain is larger in mature adults than in the elderly, in men than in women, in eminent men than in men of mediocre talent, in superior races than in inferior races. . . . There is a remarkable relationship between the development of intelligence and the volume of the brain."

The wonder is, with this background, how we have ever gotten to the point where we can now state: "Gentlemen, it is no empty rhetoric to say that women's battles are for all of us."

State of California

This document is a Technical Report submitted from the Hearing Aid Dispenser Examining Committee of the State of California. It attempts to develop a standard by which hearing aids can be measured on hearing impaired individuals which would yield criteria sufficient to differentiate between acceptable and non-acceptable fittings. On the whole, this reviewer believes that the authors have succeeded admirably in demonstrating that such a standard is indeed possible.

A review of the literature shows that it is pointless to defend further the value of speech stimuli as reliable, repeatable measures of hearing aid function. It is obvious that accurately measurable acoustic signals should be employed. In the place of speech signals, narrow-bands can yield the best results in sound field, as they are effective in smoothing the sharp peaks and valleys introduced into response curves as a function of acoustic reflection.

The signals of choice are bands of random noise the width of a critical band with a roll-off characteristic of 32 dB per octave or greater at 500, 1000 and 2000 Hz. (Steeper roll-off characteristics will be required for individuals with hearing loss contours greater than 32 dB per octave).

A quiet room is recommended in which the ambient noise on the "B" scale will be 50 dB-B or less. This should not interfere with threshold measurements of the signals selected.

Measurements at the location of the head should be taken in sound pressure level (SPL), not re: audiometric zero. Subjects should be placed nine inches from the sound source. The tests with the aids should include:

- Initial setting of a MCL when a 60 dB SPL shaped speech noise signal is presented in a sound field.

- Aided threshold measurement of narrow bands. (Unaided thresholds having been obtained)

- Aided tolerance levels, presenting the narrow bands in 5 dB steps from 70 dB to 90 dB maximum.

- Harmonic distortion measurements of the aids.

- Minimal acceptable acoustic gain should be at least 30% (PdB 30) of the unaided value for narrow bands measured at 500, 1000, and 2000 Hz.

- No tolerance problem should be reported in the 70-90 dB range of presentation of the narrow bands.

- Harmonic distortion should not exceed 25% total distortion when the gain curve at 500, 1000 and 2000 Hz is relatively flat (+3 dB).

The authors tested their standard on seventeen adult individuals ranging in age from 3 to 81 years, who had been habitual users of hearing aid amplification for at least one year.

- On the tolerance level assessment, 8 ears failed at one or more test frequencies, 8 on the retest.

- On the PdB 30 criterion, 1 ears failed at 500 Hz, 12 failed at 1000 Hz and failed at 2000 Hz.

- On the harmonic distortion test 7 failed at 500 Hz, one at 1600 Hz.

The opinion of the authors was that the recommended standard was reasonable even in view of the failure rate evidenced by the study. The magnitude of the differences between the various measures were small, and it was felt that any of the hearing aids could have met the standard with proper adjustments. They therefore recommend that hearing aids be subjected to mandatory performance standards such as these.

There is no question that accurate measurement standards are sorely needed, and that the procedures outlined here have been well thought out. The authors are to be commended for taking a strong stand against the use of speech stimuli in the evaluation of aids, and for producing realistic alternatives. It is hoped that they will think through the weakest link in the process: that of the setting for MCL, which as described depends on the subjective judgment of the wearer of the aid. Once this hurdle is overcome it would seem reasonable to begin to make such standard measurements mandatory.

hearing impairment, the click is a good indicator of the entire audiogram. On the other hand, with a steeply sloping loss, click evoked brainstem potentials will overestimate the degree of hearing impairment. Conversely, when low frequency loss predominates, click-evoked brainstem responses may indicate normal hearing when, indeed, a significant loss is present.

At the Ear Research Institute the technique of derived brainstem potentials using high-pass masking has been used to solve the frequency specificity problem.

The brainstem response to a broad-band click is first recorded and stored in the computer. The procedure is then repeated in the presence of 8 kHz high-pass masking noise. The resulting brainstem response represents the contribution from the entire cochlea except for the 8 kHz and above region, that portion which was masked by the high-pass noise. The second response is then subtracted from the first response and the brainstem response which arose from the 8 kHz region and above portion of the cochlea results. This procedure is repeated with successively lower cutoff frequencies of the masking noise. Octave-wide contributions from the cochlea to the brainstem response are thus recorded. Early experience with this technique indicates that it may be possible to reconstruct the audiogram with sufficient accuracy to confidently fit a hearing aid in a very young patient.

Ideally all children with a high risk of hearing impairment would be identified with the cribogram and impedance audiometry. Confirmation of the degree of loss would then be made by brainstem audiometry and definitive treatment begun at least by the age of six months.

Brain Development and Language Disabilities

Peggy C. Ferry
Vanderbilt Univ. School
of Medicine
Nashville, TN

The brain is precocious in its development, the major anatomic landmarks being formed by 10 weeks gestation. Neurophysiological reflexes are observed as early as 7 weeks of gestation. Thus, the truly "critical" period of brain development is in the first 10-12 weeks of fetal life.

Hemispheric specialization for language development begins prior to birth. Anatomic evidence of a larger left planum temporale is evident as early as 29 weeks gestation.

Sexual differentiation of the brain depends upon exposure of the fetal brain to male hormones during pregnancy. Girls acquire language earlier than boys, possibly because hemispheric specialization is more evident in females earlier in development than in males.

Many neurologic disorders are more common in boys than girls, particularly language and learning disabilities. The left temporal lobe in boys appears to be particularly vulnerable to injury during early life.

Clinical entities which are being found with increasing frequency

to be associated with delayed language development include neonatal asphyxia, hyperbilirubinemia, bacterial meningitis, and cytomegalovirus infection.

Further basic research into areas of fetal neurology as they are related to brain and language development will increase our knowledge of the diagnosis, management, and prevention of childhood language disorders.

Auditory Processing Deficits in Children With a History of Chronic Middle Ear Problems

R. Ray Battin, Ph.D.
Hugh Conway, M.A.
Battin Clinic
Houston, TX

This study was designed to investigate if children with a history of early, chronic middle ear problems would demonstrate more severe deficits in the auditory modality than those learning disabled without such a history.

Records of 293 youngsters from predominantly white, upper middle class families were coded for computer analysis. Of these 293 children, 99 (37%) had a history of ear (aches), ear infections, running ears or fluid.

The following test battery was administered: The Illinois Test of Psycholinguistic Abilities (ITPA), The Wechsler Intelligence Scale for Children—Revised (WISC-R), or the Stanford-Binet, test of intelligence, the Peabody Individual Achievement Test (PIAT), and the Goldman-Fristoe-Woodcock Test of Selective Attention.

The profile of the ITPA, the intelligence tests, and the PIAT indicated no significant differences among the two groups.

Using the same test battery described above, 26 additional youngsters with a history of middle ear problems were seen. With this population the parents were also interviewed. Results from this group when compared to the previous population were the following:

1. Slightly higher scores in the full scale intelligence test.
2. Stronger auditory reception and auditory association skills but a slightly greater depression in verbal expression.
3. Deficits in handling listening in noise.

In summary, our findings suggest that while children with a history of middle ear problems do indeed show a profile reflecting deficits in the auditory-verbal mode, these deficits are not as severe as other "learning disabled" children. Furthermore, the child's environmental, developmental and health history should be considered when attempting to study the effects of early middle ear problems.

The Effect of Mild to Moderate Hearing Loss on Learning the Language of Mathematics

Moya L. Andrews
and Cynthia J. Brabson
Indiana University
Bloomington, Ind.

Many linguistically handicapped children have difficulties in learning mathematics. Such children have a double handicap. They encounter the language of

mathematics, a language which itself has a variety of both oral and written representations, in a classroom where the language of instruction is already a problem for them.

There is now additional evidence to suggest that even mild to moderate hearing losses, such as those resulting from recurrent middle-ear disease can contribute to a general, though in some cases subtle, linguistic problem which subsequently affects the learning of basic mathematical concepts. Relational ideas are particularly difficult for children to understand if they do not hear the entire sentence and process only part of the information provided.

Many unstressed words such as prepositions are critical in understanding certain oral arithmetic problems. A child may not realize that "add" and "and" words perceived to have similar oral movements, have different written forms. Similarly, the child may have trouble sorting out the various words used in problems to express the concept of addition. Teachers may use "combine, bought more, found more", or "got another" for example. Lessons that stress the relationship between the fundamental concepts and the various symbolic representations of these concepts are important. Piaget's (1965) approach to mathematical concept development is also helpful in planning programs to suit children with these special needs.

The Effect of Mild to Moderate Conductive Hearing Loss on Language Development in Children with Neurological Impairment

Sylvia M. Davis, Ph.D.
and Vincent W. Byers, Ph.D.
Department of Audiology and Speech Pathology
Louisiana State University
Medical Center
New Orleans, La. 70119

Customarily, the development of language has been considered to begin with the appearance of first words; however, evidence suggesting that language development begins at birth continues to mount. Without a doubt, language is highly dependent upon auditory skills. Results of recent investigations have revealed that even mild conductive hearing problems, if recurrent, may have deleterious effects on language learning. When abnormalities within the auditory system are detected during infancy or at some point during the language learning years, the child is in need of some medical attention and services of communication specialists.

The obvious rationale for early detection and intervention is that young children are more amenable to skill acquisition than are older children and that secondary handicapping conditions can possibly be prevented. The purposes were: 1) to describe hearing status for the children between zero and three years of age diagnosed as having neurological disorders; 2) to describe language assessment and management procedures utilized with children who present differing neurological impairments; and 3) to discuss the effects of mild to moderate conductive hearing losses on language development in children with neurological impairment.

Hearing assessment and language assessment procedures were repeated at periodic intervals during a 24-month period. Analysis of these longitudinal assessments suggests that middle ear pathology in a neurologically impaired group does not necessarily impede the normal course of language development. Some of the children with middle ear pathology do show a marked delay in language development. While other children with equal or greater middle ear pathology show no language delay. All children demonstrated a language age commensurate with their mental age derived from psychological assessments conducted at 6-month intervals.

The variable of middle ear pathology appears to be a factor in language delay, but it must be examined within a context of other variables if a language delay is present. Possible variables that seem to warrant consideration include: age of onset of middle ear pathology, degree and duration of the loss, stiffness of middle ear system and other handicapping conditions. Also, language intervention and stimulation procedures following early identification, may alleviate or impede deleterious effects on language development.

Audiometric Evaluation of Infants 12-18 Months of Age

Bonnie Forman-Franco and
Allan L. Abramson
Division of Otolaryngology and
Communication Disorders
Long Island Jewish/Hillside
Medical Center
New Hyde Park,
New York

Behavioral Observation Audiometry (BOA) in conjunction with Acoustic Impedance studies has infrequently been evaluated in the 12-18 month infant population. Therefore, a one year prospective

study, was done to gather additional psychoacoustical measurements on this select age group.

Subjects included 73 children (42M, 31F) from the Long Island Jewish/Hillside Medical Center's neonatal registry, seen between the ages of 12 and 18 months. All infants had audiologic evaluations consisting of speech detection and hearing threshold levels sound field and under headphones. Electroacoustic impedance including tympanometry, compliance and acoustic reflex measurements were also attempted.

Complete audiometric results were obtained from 75% (55) infants during the initial audiometric evaluation; 73% (53) provided binaural tympanograms. Only fifty percent of the patients cooperated for all four frequencies attempted on the acoustic reflex studies with a 4% incidence of absent reflexes. Impedance studies confirmed audiometric findings in 77% of the infants evaluated.

Audiometric testing including tympanometry and acoustic reflex measurements have become an important tool in screening the pediatric population. Early detection of a hearing loss is important in the development of speech and language as well as the start of any rehabilitative therapy.

Attempts were made to determine psychoacoustical measurements utilizing BOA and acoustic impedance on seventy three 12-18 month old children. The greatest difficulty encountered in this study was the lack of infant cooperation. Seventy three percent of the population cooperated for tympanometry; seventy five percent cooperated for behavioral observation audiometry. These findings suggest a correlation of reliability between BOA and impedance testing in this select age group. Of the patients who were cooperative for acoustic reflex testing at 500, 1000, 2000, and 4000Hz, four percent elicited no responses. It is generally accepted that there is a five percent no response rate in adults. Of the sixty three percent having acoustic reflex responses, an estimated ten to fifteen percent provided behavioral rather than elicited responses. Nineteen percent failed either form of testing requiring further follow up care.

If reliable acoustic measurements are to be achieved when testing an infant population, then a comprehensive hearing testing program consisting of combined behavioral observation audiometry and impedance studies should be performed.

Purdue Sponsors Telecourse

Purdue University, in cooperation with the Indiana Department of Public Instruction, Division of Special Education, is pleased to offer this telecourse. Its purpose is to assist speech-language pathologists, audiologists and special educators in keeping pace with new information and clinical advances as they relate to the communicatively handicapped preschool child.

The focus of the course will be on identification of, and management techniques for young children with hearing loss. A broad range of pertinent topics including materials for language, speech and auditory intervention will be provided. Issues concerning educational services, alternative communication modes, and infant programs will also be discussed.

The telecourse will utilize the facilities of the Indiana Higher Educational Telecommunication System (IHETS). Participants will view LIVE telecasts originating from the Purdue University, West Lafayette Campus. Telereponse units (talk-back) at each center will make possible teacher/learner interaction. To assist in the mastery of the material presented, the following learning resources will be available:

1. A toll free telephone "hotline" will be maintained throughout the semester for persons wanting individual conferences with the instructor.

2. Participants wishing to review earlier lectures may request 3/4" color videotape cassettes, audiotape cassettes (regular speed), and audiotape cassettes (compressed speed-reduces listening time 50%).

Persons interested should contact: Robert G. Showalter, M.A., Associate Professor, Audiology and Speech Sciences, Purdue University, West Lafayette, IN 47907. Phone: (317) 494-8006.

Maico Features Computer Audiometer

A new, 4-color brochure featuring the Maico MA26 Computer Audiometer is now available from Maico Hearing Instruments, Inc., Minneapolis, Minnesota.

This 6-page descriptive brochure provides important information for your company's hearing conservation program. It explains how, by using the MA26 Computer Audiometer, you can cut employee hearing test time by 30% or more, minimize errors, and yet achieve greater accuracy in testing.

The MA26 Computer Audiometer presents an automatic

printout of test results for each employee, including step-by-step documentation of each threshold. This data can also be transmitted to your company's main computer. The printout record can become a permanent part of an employee's personnel file, and can assist you should medical compensation questions arise.

For a free MA26 Computer Audiometer brochure with complete specifications, write to Maico Hearing Instruments, Inc., 7375 Bush Lake Road, Minneapolis, Minnesota 55435 or call our toll free number 800-328-6366.

International Symposium on Amplification in Education

An International Symposium on Amplification in Education sponsored by the Bill Wilkerson Hearing and Speech Center will be held in Nashville, Tennessee on September 26, 27, and 28, 1979. Some of the general program topic areas include: Sensory capabilities of hearing impaired children, Educational uses of classroom amplification, Desirable characteristics of amplification systems, and Selection of amplification systems. In addition, registrants will have the opportunity to participate in small group workshops on the applications of different types of amplification systems, measuring the classroom environment,

and the use and care of classroom amplification. Some of the faculty include Eric Wedenberg, M.D., who will present the W. W. Wilkerson Memorial Lecture, Arthur Boothroyd, Ph.D., Julia Davis, Ph.D., Marion Downs, M.A., Norman Erber, Ph.D., Gloria Hoversten, M.A., Vernon D. Larson, Ph.D., Daniel Ling, Ph.D., Andreas Markides, Ph.D., Noel D. Matkin, Ph.D., Wayne Olsen, Ph.D., Steffi B. Resnick, Ph.D., Mark Ross, Ph.D. and Daniel M. Schwartz, Ph.D.

For further information contact Vanderbilt Continuing Education, 305 Medical Arts Building, Nashville, Tennessee 37212.

Glorig Receives CRS Amplifon Award

Past AAS president Aram Glorig has been awarded the cherished Amplifon CRS (Research and Study Center) Award. The award, which carries a \$6,000.00 cash prize, and awarded each year, is bestowed on an outstanding researcher who has contributed to the advancement for studies on deafness. Candidates are nominated for the award and reviewed by an International Prize Committee of 19 members. Mr. A. C. Holland, in announcing the award to AAS, said that Glorig was elected unanimously.

Award ceremonies will be held in the spring, both in Milan and, if possible, in the U.S.A.

Aram Glorig

West Virginia Speech & Hearing Assoc. Holds Spring Meeting

The Spring Convention of the West Virginia Speech and Hearing Association will be held April 18-21, 1979, at the Ramada Inn in South Charleston, WV. This year's convention will be high-

lighted by an outstanding list of guest speakers including Kenneth Berger, Ph.D., Kent State University; Eugene Cooper, Ph.D., University of Alabama; Frederick Darley, Ph.D., Mayo

Clinic; Stephen Kasden, M.S., Pawtucket, R.I.; and Derek Sanders, Ph.D., State University of New York, Buffalo. For further information contact Richard L. Squires, President-Elect

WVSHA, c/o West Virginia Speech and Hearing Association, P. O. Box 3699, Charleston, WV 25335.

Noise/News Begins Eighth Year Of Publication

NOISE/NEWS, published bi-monthly for the Institute of Noise Control Engineering, begins, with the January-February 1979 issue, its eighth year of serving the noise control community. During this period, there were two very significant bills passed by the U.S. Congress: the Noise Control Act of 1972 and the Quiet Communities Act of 1978. The Occupational Safety and Health Administration (OSHA) also took important steps towards a revision of its workplace noise regulation and federal agencies such as EPA and DOT have issued many proposals and regulations concerning noise. All of these items have been regularly reported in NOISE/NEWS.

More than 1500 government reports on noise have been listed, and contract award information is published regularly. Standards

news and news of national and international noise Conferences appears in each issue. A limited number of specimen

copies of NOISE/NEWS are available upon request in order to acquaint potential readers with the content of NOISE/NEWS.

Copies may be obtained by writing to NOISE/NEWS, P. O. Box 1758, Poughkeepsie, NY 12603 U.S.A.

INCE To Sponsor Noise-Con Seminar

The Institute of Noise Control Engineering (INCE) will sponsor a Seminar on Noise Control, the NOISE-CON Seminar, in conjunction with the 1979 National Conference on Noise Control Engineering (NOISE-CON 79).

The Seminar, to be held at Purdue University in West Lafayette, Indiana on 26-28 April 1979, will emphasize the fundamentals of noise control engineering, machinery noise control, in-plant noise, and measurements and facilities for noise control. The staff for the Seminar is made up of

practicing noise control engineers selected by the INCE Board of Directors.

This is the eighth Seminar which has been organized by the Institute to acquaint individuals just entering the field with the basic principles of noise control and with practical methods for control of machinery and in-plant noise.

The fee for the NOISE-CON Seminar is \$375.00 which includes all texts and lecture notes and a copy of the NOISE-CON 79 Conference Proceedings. The Conference itself, which will be held

on 30 April - 2 May, has the theme "Machinery Noise Control." It is sponsored jointly by the Institute of Noise Control Engineering and the R. W. Herrick Laboratories, Purdue University.

A NOISE-CON Seminar flyer will be available in mid-February; the flyer will contain information on the content of the Seminar, the staff and registration forms. For further information, write to the NOISE-CON SEMINAR, P. O. Box 3469, Arlington Branch, Poughkeepsie, NY 12603 U.S.A. or call (914) 462-6719.

International Electric Response Audiometry Study Group Meets

MEETING:

The International Electric Response Audiometry Study Group will hold its biennial symposium on the campus of the University of California, Santa Barbara, from Monday, August 6, through Thursday, August 9, 1979. The meeting will be hosted by the Speech and Hearing Center of the University of California, Santa Barbara.

PROGRAM:

The scientific sessions of the Symposium will be devoted to all aspects of ERA including electro-cochleography, brainstem evoked potentials, cochlear

microphonic and summing potentials, frequency following responses, middle evoked potentials, late evoked potentials and the contingent negative variation—all depending on the topics of submitted abstracts. The sessions will include short lectures (15 minutes), special invited lectures, round table and group discussions and demonstrations of the recording in man of the various evoked potentials. Topics for round table discussions are invited.

Members who are interested in presenting lectures are invited to submit according to the following tentative deadlines:

Lecture Titles—January 15, 1979.

Lecture abstracts (250 words)—March 31, 1979.

Registration—April 31, 1979.

In addition, there will be a social program, a tour of the Santa Barbara area, and a separate accompanying persons program.

Titles, abstracts and requests for further information should be addressed to:

M.I. Mendel, Ph.D.
Speech and Hearing Center
University of California
Santa Barbara, Calif. 93106 USA

Free Volumes Of NCE For New INCE Associates

The Institute of Noise Control Engineering has announced that two free volumes (six issues) of the bimonthly technical publication **Noise Control Engineering** will be given to individuals who become new Associates of the Institute in 1979. The offer, intended to encourage individuals interested in noise and its control to participate in the activities of the Institute, will enable new Associates to begin building a library of back issues of NCE, the only publication in the United States which publishes refereed articles devoted exclusively to noise control.

Any individual interested in noise control may become an Associate of INCE; Associates

receive the bimonthly publication **Noise/News** in addition to NCE. **Noise/News** contains articles of broad interest in noise control, reports of federal regulations and legislation, contract information, lists of government reports and other useful noise control information. Associates also receive mailings of meeting programs of National and International Conferences organized by the Institute.

The INCE Associate application form and specimen copies of both **Noise Control Engineering** and **Noise/News** are available from the Membership Secretariat, INCE, P. O. Box 3206, Arlington Branch, Poughkeepsie, NY 12603 U.S.A.

July, 1979

'Mr. Ear' To Be Carhart Lecturer

The annual AAS Carhart Lectureship Award goes this year to Aram Glorig, founder and first president of AAS. The Executive Committee voted unanimously to designate Glorig for the 1979 honor. This prize follows closely the April Amplifon Research and Study Center Award he received in Italy, culminating the most distinguished career in the medical-audiology profession.

Glorig was indeed one of the first Medical Audiologists in history and deserves the title "Mr. Ear" for his life-long devotion to auditory problems. Together with Norton Canfield he helped develop the field in the Army where Raymond Carhart also began his career. Following World War II Glorig became head of the Walter Reed Speech and Hearing Center, where he established the complete hearing aid and aural rehabilitation service that has been used as a model ever since.

In 1952 Glorig became director of the AAOO's Sub-Committee on Noise in Industry. There he put out the classic studies on the

effects that became the basis for all noise-in-industry programs.

In 1960 Glorig became Director of the Callier Hearing and Speech Center in Dallas. He built this center into a facility that became a model for education of the deaf, audiological services and research activities. He continued to direct investigations into noise effects as well as other areas related to hearing. On his retirement from Callier in 1977 he became director of Research for the Otologic Medical Group in Los Angeles, where he continues to make outstanding contributions. In the April 1979 issue of the Journal of the American Auditory Society he gave a classic report on Hearing Loss in the Aging that should be read by all audiologists.

Glorig's great emphasis on noise in Industry makes it appropriate that his title for the Carhart Lecture will be: **Noise: Past, Present and Future**. It will be a rewarding experience for AAS members and guests to hear this great statesman in the field of audition. AAS will be proud to salute "Mr. Ear."

Simmons Arranges AAS Program

Blair Simmons as Program Chairman for the 1979 meeting has put together a program to top even the outstanding offerings of last year. He has arranged special talks on Mondini deafness by Michael Paparella and by William and John House, as well as reports on Evoked Responses and other topics (see complete program below).

The highlight of the program will be the Carhart Memorial Lecture by Aram Glorig entitled:

Noise: Past, Present and Future.

It is appropriate that this program will be held in conjunction with the Academy of Otolaryngology meeting in Dallas. It will begin at 8:30 October 9th and take up the entire morning.

Simmons has arranged with the Academy to have this meeting a recognized activity of the Academy. The AAS meeting will be held in room E410 at The Dallas Convention Center. A preregistration form and program are on page 9.

AAS Journal Veers to 'Ears'

(Editor's Note: Just as we are going to press comes the news that The Journal of the American Auditory Society will undergo a major change and it will be vastly expanded. President Sam Lybarger gives us a summary of the changes in the following story).

As a result of two conferences in Baltimore with Williams & Wilkins, publisher of the Journal of the American Auditory Society, that were attended by Don Harris, Ross Roeser and myself for AAS and Alma Wills and Jim Gallagher for Williams & Wilkins, a new plan for our journal was worked out and has been approved by the AAS Executive Committee.

Starting with the first issue in 1980, the journal will have a broader scope that we believe will be extremely interesting to our members and to other subscribers. In addition to the present type of original articles, the new format will add a series of regular sections to bring additional useful ideas and information to serve the varied needs of our membership. Such new sections as book reviews, techniques and applications in hearing aids, foreign translations, residents and interns page, clinical notes and invited editorials are under consideration. Advertising space will be made available and advertising solicited by Williams & Wilkins.

To emphasize the fact that we are beginning a fresh, new concept for our journal, a new name will be adopted starting in 1980. The new name will be:

**EAR and HEARING
Journal of the
American Auditory Society**

Ross J. Roeser has accepted the assignment of Editor-in-Chief of the new journal and is already in the process of building his editorial staff for the regular sections to

be added. Ross's dedication and enthusiasm with respect to AAS matters will be of tremendous importance to the success of the new undertaking.

J. Donald Harris will continue as an important editor in the new journal, covering the area of original articles with the expertise that he has demonstrated as Editor-in-Chief of our present journal. Don will remain Editor-in-Chief for the journal in its present format through 1979, completing the three remaining issues to be published this year.

Alma J. Wills is the person at Williams & Wilkins responsible for publication of American Auditory Society journals. She is an experienced and competent individual who contributed many of the ideas for the new journal and who is enthusiastic about making our journal very successful.

To make the new Journal a financial success for ourselves—that means keeping dues at as low a level as possible—and for Williams & Wilkins—that means returning a fair profit—we need the help of every member to increase our membership. In attending various meetings earlier this year, I found many people unaware of AAS and the fact that it was formed to foster cooperation between the medical, audiological and hearing aid professions. Many of these people need only to be told about AAS and asked to join our Society. We need a vigorous membership campaign and you will be hearing more about this in the near future.

Let's give our new editorial staff our fullest cooperation and support for the great job that I know they are going to do.

A final word—Corti's Organ will, of course, be continued in its highly successful form.

Sam Lybarger, President

Aram Glorig

Program of the 1979 AAS Annual Meeting

8:00—Registration opens

9:00—Metabolic Mapping of Cortical Activity. William F. Rintelmann.

9:15—Binaural Interaction in Human Auditory Evoked Responses. Robert A. Dobie.

9:30—Mondini Deafness: Theory and Results of Endolymphatic Shunt Surgery. William House and John House.

9:45—Mondini Deafness: A Review of Temporal Bone Histology. Michael Paparella.

10:00—Percent Hearing Loss: What You See Ain't What You Get. Niel Ver Hoef.

10:15—The Effectiveness of Rescreening in a School Conservation Program for Conductive Hearing Loss. R. J. Pellerin and J. C. Cooper, Jr.

10:30—Recovery of Suprathreshold Auditory Test Function after Removal of C.P.A. Tumors. G. Richard Holt.

11:00—Brainstem Evoked Response Audiometry Results from Hydronic Patients. Claude P. Hobeika, Dorsey Ann Flemming, Andrea B. Rappaport, and Gayle P. Riemer.

11:30—Word Discrimination in Quiet and Noise by Children and Adults: A Second Look. Gail D. Chermak, and Joan Dengerink.

11:45—Aram Glorig's Carhart Memorial Lecture: Noise: Past, Present and Future.

12:45—Business Meeting.

Editorial

A TRIBUTE TO J.D.

In this issue is announced a radical change in the Journal of the American Auditory Society. A new name, a new editor, a new format, a new editorial policy—all designed to stimulate circulation at a time when competition is running wild among new rival journals. Whether Ear and Hearing will win, place or show remains to be seen, but it should fill a particularly valuable cross-disciplinary niche.

AAS is strongly indebted to J. Donald Harris for presiding at the starting gate of the Journal. From scratch he developed a new publication, using all the facilities at his command to make it go. No one else could have given the journal an immediate impetus nor molded it into a scholarly event.

J. D. maintains such a low profile that few people recognize the tremendous contribution he has made to the profession in general and to AAS in particular. A Renaissance man, he was once described in Corti's Organ as "a pianist of stature, a classical scholar, an appreciative naturalist and a philosopher of the

Letter from England

Dear Editor:

Among the fringe benefits of being an itinerant symposiast nothing could have given me more pleasure than the opportunity of meeting you and other friends again. The occasion was the Second International Symposium on Recent Advances in Otitis Media with Effusion in Columbus: inspired by our dear friend Ben Senturia and splendidly organized by David Lim. A most successful meeting; whose conclusions and directives will guide our work for many years to come.

It is interesting to note that also on this side of the Atlantic interest in Otitis and its sequelae has been growing, e.g. in epidermoid cholesteatoma, cholesterol granuloma (see recent papers in the Journal of the Royal Society of Medicine and Journal of Laryngology).

I cannot help wondering why some of the well founded histopathological and experimental findings continue to be ignored by some workers.

On the way to Columbus a week

in New York has given us the opportunity not only to enjoy revisiting the Rockefeller University, an oasis of flowers around the hallowed old and new buildings of this great institution, but also to applaud the progress of the team Ruben-Vande Water at Einstein. There was more to come in Los Angeles where the Ear Research Institute never ceases to inspire and stimulate me. About that in my next letter.

We have returned to England in a terrifying thunderstorm and drove home from the airport in blinding rain. But at last the anticyclone from the Azores has moved nearer to England and we have enjoyed a walk in the nearby woods without wearing a raincoat. Since a gallon of petrol now costs £1.12p, that is more than two dollars, walking is good for the health of senior citizens, if you know what I mean.

Wimbledon is coming... you will be joining us in watching on television the progress of your famous 'Superbrat'!

—Imre Friedmann

Minnesota Hosts Sensorineural Symposium

An International Symposium on Sensorineural Hearing Loss, Vertigo and Tinnitus is being presented by a group from the University of Minnesota headed by Mike Paparella. It will be held under the combined sponsorship of the University, Hearing Instruments Institute and Lions International District 5M.

An extensive faculty includes: Hugh Barber, M.D.; Charles Berlin, Ph.D.; D. Thane Cody, M.D.; Bud Danylchuk, D.D.S.; Hallowell Davis, M.D.; Arndt Duvall, III, M.D.; William Ely, M.S.; Michael Glascock, III, M.D.; Robert Gorlin, D.D.S.; Marcos Goycoolea, M.D.; Jacabo Guzowski, M.D.; Jerome Hilger, M.D.; Howard House, M.D.; William House, M.D.; James Jerger, Ph.D.; John Kenwood, Frank Lassman, Ph.D.; Gunnar Liden, M.D.; David Lim, M.D.; John Lutter; Ralph Lynam; Brian McCabe, M.D.; David McCullough, M.D.; Tetsuo Mori-

sciences as well as of the arts." He has "demonstrated his deep comradeship with classical literature and arts, and has shown in his speaking and writing an abiding love of the English language."

We thank J.D. for coming to the aid of the infant Auditory Society and lending his great resources to the start of its journal. No scholarly society can be successful without a scholarly publication, and J.D. has gotten us off and running in his exemplary style. There are few scholars of his ilk still around and we hope he will continue to be an elder statesman for this growing society.

MPD & RJR

Telephone Pioneers Pioneer BSER

Brain stem evoked response testing has been reported at numerous learned societies, but a group of volunteers is making the technique available on a mass basis. The Telephone Pioneers of America are a group of veteran telephone employees who are committed to supporting projects to aid communicative disorders. With the guidance of Phillip Peltzman, San Francisco audiologist and EEG experts, they are manufacturing a simple screening BSER unit capable of rapidly screening the hearing of newborn babies.

The Pioneers are providing the instruments plus trained volunteers to do the testing in field trials in various hospitals in California and other states. The information from the screening test goes to a central computer in San Francisco, where statistics will be recorded and the results interpreted.

Peltzman is a former member of the Joint Committee on Infant Hearing Screening of ASHA, Pediatrics and Otolaryngology. He has published extensively on EEG recordings in neonates.

Glorig Receives Prize For His Contribution

The 1978 Amplifon Research and Studies Centre International Prize was awarded to Dr. Glorig, a world known U. S. Otolologist, for his outstanding contribution to the study of industrial noise deafness, through which both public awareness of the hazard and U. S. legislation to prevent it were obtained.

Dr. Glorig was awarded the prize (worth approximately \$6,000 and considered the most important honour for audiology) at the Milan (Italy) Press Club on the 5th of April, 1979, where a packed assembly of his colleagues listened to Prof. Gino Sacerdote, former Director of the "Istituto Galileo Feraris" of Turin, extolling his praises. Industrial noise and its harmful effects on hearing is a dramatic problem in today's world and its importance has now been finally recognized in Italy, involving both

public opinion and scientific and political awareness.

Therefore the attribution of the prize to Dr. Glorig was particularly useful to attract public attention to this problem, in Italy, and to stress the importance of finding the means to solve it.

On the 6th of April, after the prize ceremony, Dr. Glorig was the guest of honour at a meeting organized by the Italian State Occupational Insurance Organization, (INAIL), where he delivered a highly successful "magistral lecture" before over 300 delegates.

Previous CRS prize winners have been: Prof. Tokura Suzuki (Japan), Prof. Erik Wedenber (Sweden), Prof. Hallowell Davis (U.S.A.), Prof. James Jerger and Prof. Jozef J. Zwislocki (U.S.A.), Mrs. Suzanne Borel Maisonn (France) and Prof. Michele Anslan (Italy).

Dr. Aram Glorig being presented with the Amplifon CRS International Prize by Mr. Charles Holland at the Press Club in Milan (Italy).

Milan, April 5th, 1979

**AAS
Annual
Meeting
Oct. 9**

Report From British Society of Audiology

A meeting of the British Society of Audiology was held in London on April 27, 1979. The chairman of the meeting was Mr. M.C. Martin, O.B.E. The following are abstracts from the meeting:

CURRENT TRENDS IN THE USA

by Samuel F. Lybarger

Acoustical Consultant Mc-Murray, Pennsylvania, USA

Governmental regulation of "medical devices" by the U.S. Food and Drug Administration includes hearing aids. ANSI Standard S3.22 was developed with the aim of providing highly reproducible test methods and is used in FDA regulations to compare actual hearing aid performance to that stated by the manufacturer. One new concept in this standard is the use of the "entrance pressure method" of determining input sound pressure level.

Other areas of activity in the USA are:

"In-situ" measurements of hearing aids using the KEMAR manikin or free-field testing of individuals with hearing aids by dispensers.

Determination of desirable frequency response in hearing aids; the work of Pascoe is of particular interest.

Wide-band hearing aids with specialized earmold "plumbing" proposed by Killion.

Signal processing in hearing aid amplifiers for noise reduction (Graupe and Causey) or for special types of compression.

Tinnitus research and the use of tuned random noise maskers.

PSYCHOACOUSTIC FACTORS RELEVANT TO DESIGN OF HEARING AIDS TO COMPENSATE FOR SENSORIENEURAL HEARING LOSS

by B. C. J. Moore

Department of Experimental Psychology, University of Cambridge

The differences between normal listeners and those with sensorineural hearing impairments are described in relation to the following basic psychoacoustic factors: loudness, masking, lateral suppression, pitch perception and temporal acuity. The effect of these differences on the ability to identify and discriminate sounds is discussed. It is concluded that conventional hearing aids can only be of limited benefits, and that severe problems can be expected under conditions of background noise or high room reverberation.

The rationale and drawbacks of hearing aid designs (such as multi-channel compression) which attempt to compensate for sensorineural hearing loss is discussed. In some cases of sensorineural hearing loss the ability to extract information from acoustic inputs may be so limited that speech comprehension will only be achieved by a combination of acoustic and lip - (speech) read information. In these cases there may be an advantage in extracting prosodic features from the speech, and presenting only those features.

TOWARDS A SCIENTIFIC BASIS FOR HEARING AIDS

P. L. Lyregaard

Oticon Research Unit
Snekkersten, Denmark

The hearing aid of today is, despite many years of development, little more than an amplifier of sound. Recent developments in microelectronics have opened up vast possibilities of processing the acoustic signal before reaching the ear, but the type of processing likely to benefit hard-of-hearing persons most remains to be determined.

Evidently the starting point should be the characteristics of the hearing impairment to be alleviated by the hearing aid, and the acoustical characteristics of the signal, but it would appear that scientific investigations of the psychoacoustics of auditory disorders are much less advanced than in the case of normal hearing.

It is also timely that the art of selecting and adjusting a hearing aid to a particular hearing impairment be scrutinized such that, hopefully, hard scientific fact may prevail over the present intuitive approach.

"WHERE DOES THE USER WANT TO GO?"

Mr. J. Neville Brown

Engrams Hearing Aids
2 Shepherd Street, W.I.

Every hearing aid user knows the answer to that question without hesitation. He wants to go straight to what he believes would be the ultimate stage; he wants to have a hearing aid that cannot be seen when in use, that requires no manual adjustment, and that gives him perfectly normal "natural" hearing. Most users would be prepared to forego the first two requirements if the third one could be attained; although in practice, the achievement possibilities would appear to be the other way round.

With the user's viewpoint in mind, some questions are made, and some suggestions asked, in the hope that they may give some indication of the answer to the question "Where do we go from here?"—or, at the very least "Where should we be trying to go from here?"

RECODING OF SPEECH FOR THE DEAF

Dr. M. Velmans

Department of Psychology
Goldsmith College, London

In cases of sensorineural hearing loss, where residual hearing exists only in the low frequency region (e.g. below 2 kHz) selective amplification may be insufficient to restore intelligibility to speech. Under these circumstances it may be desirable to "Recode" information normally distributed in the higher frequencies (e.g. 2 to 8 kHz) into a detectable low frequency form.

In general, the rationale underlying recoding device design has proceeded largely from informa-

tion theory or engineering considerations e.g. focussing on how to "squeeze" information normally occupying an 8 kHz bandwidth into a 2 kHz bandwidth. It appears, however, that the degree of added benefit which may be obtained by recoding varies considerably with the mode of recoding employed, with the residual hearing bandwidth and with the relative ability of patients to make use of their residual hearing.

A given recoding technique, therefore, if it can be shown to be of benefit, should be supplied in the context of a "clinical package." This would consist of a procedure for diagnosing those patients likely to benefit from the technique, means for fitting the device (e.g. for setting an optimal mix of "recoded" and "non-recoded" information) and means for assessing the precise benefit obtained. An example of one such "clinical package" currently under development, will be discussed.

DESIGN PHILOSOPHY OF EQUIPMENT FOR HARD OF HEARING CHILDREN

Mr. Thaler
Siemens Ltd.
Germany

The paper follows the development from nonaural to stereo group training systems and discusses the acoustical advantages of the stereo system. The theme is developed to discuss modern day freedom of movement systems and looks at the technical aspects of infra-red transmission. Finally the paper examines technical developments to be expected in the future.

THE EFFECTS OF HEARING AID FREQUENCY RESPONSE MODIFICATION

Mr. B. W. Lawton

B.S.V.R. University of Southampton

The miniaturisation of hearing aid components for the popular behind-the-ear aids has led in some cases to less available power and narrower, irregular frequency range. Is the frequency-restricted, amplitude-distorted amplified sound the best that can be provided? This problem is of particular importance to the National Health Service which issues aids on the philosophy that for the majority of aid users, a single frequency-gain characteristic provides optimum amplification.

A study was conducted to determine whether smoothing and extending the frequency response of the N.H.S. BE-11 (behind the ear) hearing aid would have any beneficial effects upon the speech discrimination of hearing impaired aid users. Free-field speech audiometry is quiet and in noise showed significantly improved speech discrimination using modified response hearing aids. The response changes also produced significant improvements in the judged quality of amplified sound.

A CONTROLLED FEEDBACK HEARING AID

Dr. M. J. Bennett

Clinical Measurement Section
Department of Mechanical Engineering
Brunel University, Uxbridge

A hearing aid has been devised which will accept and cancel acoustic feedback as part of its normal operation. In standard aids, acoustic feedback occurs whenever the output sound from the earpiece receiver is of sufficient intensity to excite the input microphone. The aid goes into oscillation and the output level rises to a maximum. This produces severe discomfort and possible damage to the ear. The problem is particularly severe with high gain aids and in children where their rapid growth prevents a good ear mould fit from being maintained.

The new aid shifts the input signal to produce a slightly lower frequency and amplitude at the receiver in the presence of feedback conditions. When this signal itself feeds back, it will again be shifted and the cycle repeated. This process totally inhibits feedback oscillations. In normal use the shift process is inoperative and no additional signal distortion occurs.

PRIORITIES FOR HEARING AID RESEARCH

M. C. G. Rice

I.S.V.R., The University
Southampton

The sensori-neural hearing loss patient has loudness, pitch and temporal coding inadequacies, which cannot be wholly rectified by electro-acoustic means, because no instrument can either restore or adequately substitute for degenerated sensory cells and nerve fibres.

Nevertheless efforts have been made to try and improve such patients ability to perceive sound by fitting them with some form of hearing aid. This process has been aptly described by Shipley as "a utilisation of the practitioners accumulated experience combined with a process of trial and error." In fact some forty years of research have produced no definite scientific basis for the fitting of hearing aids, and it may well be a myth to suppose we can reliably relate a patient's hearing loss to a suitable prosthesis. Furthermore we can almost categorically state that we do not know why particular hearing aids are found satisfactory by particular patients.

Assuming hearing aids can be of worthwhile value it is not unreasonable to expect that future research should be at least minimally co-ordinated if clearly identifiable and quantifiable progress is to be expected. This presentation outlined some factors felt to be worth of consideration in such a context.

Dictionary of Acoustic Terminology

The following contribution to further the state-of-the-art originally appeared in the May 1978 issue of EDI-tion published by Engineering Dynamics International, St. Louis, MO. It is republished below as an important addition to the literature.

Acoustic—Instrument issued to play billiards
Alias—Banned by consultant when moonlighting
Ambient—Not understood
Audiogram—A singing telegram
Attenuation—One more than a nine-uation
Background Noise—Wife's nagging
Baffle—Short course in acoustics
Broadcast—All girl orchestra
Broadcast—One used on a woman
Diode—Poem about death
Feedback—Upchuck
Flogging—A punishment combining flogging and spanking
Free Field—One that can be homesteaded
Frequency—One that doesn't cost anything

Ground Loop—Forward somersault
Hertz—Frequency (Avis—2nd harmonic)
Histogram—Telegram from an historian
Impact—Deed of a mischievous child
Loudspeaker—Mother-in-law
Microphone—Telephone for mid-gets
Multiplexed—Perplexed by many things simultaneously
Narrow Band—Orchestra in single file
Noise—Medical attendant in a Brooklyn hospital
Obake—Average for October
Ohm—English house
Pink Noise—Detente
Random Noise—Congressional debate
Reverberation—Replacing the verb in a sentence
Spectrum—Discharging Cuban liquor from the mouth
Standing Wave—Female naval person at attention
Transmission Loss—Clutch out

"I was hungry and you formed a committee to investigate my hunger. . .
I was homeless and you filed a report on my plight. . .
I was sick and you held a seminar on the situation of the underprivileged. . .
You have investigated all aspects of my plight. . .
And yet I am still hungry, homeless and sick."

(Continued from April Issue)

OTOTOXICITY AN IATROGENIC DISEASE

by Robert Brummett
University of Oregon

Over the past several years it has been well documented that a devastating ototoxicity can result in patients who receive both an aminoglycoside antibiotic and a loop inhibiting diuretic. The aminoglycoside antibiotics that are currently in use are streptomycin, neomycin, kanamycin, gentamicin, tobramycin, amikacin, and paromomycin. The available loop inhibiting diuretics are ethacrynic acid and furosemide. Furthermore, two experimental loop diuretics, bumetanide and piretanide interact well. None of the other classes of diuretics exhibit this interaction.

The characteristics of this interaction is that it takes place within a few hours of the time that single doses of each drug are given. The interaction effect can be monitored by a depressed ability of the cochlea to generate the AC cochlear potential and is seen about two hours after the drugs have been administered.

Clumping of the nuclear chromatin of the outer hair cells can be seen one hour after drug administration and at two hours, a loss of the smooth endoplasmic reticulum of the subsurface cisterna is seen. Four hours later the cells are markedly damaged and may be dead. Alterations in the mitochondria are not seen before 4 hours.

While this effect is rather specific for the loop inhibiting diuretics, it is not so specific for the aminoglycoside antibiotics. All of the aminoglycoside antibiotics can produce the interaction, but in addition, so can the non-aminoglycoside antibiotics; viomycin, capreomycin and polymyxin B. The antibiotics, vancomycin, polymyxin E and spectinomycin do not produce the interaction. It, therefore, appears that antibiotic induced interactions with the loop inhibiting diuretics may be a much more general phenomenon than is currently believed and special attention should be directed to monitoring auditory function in patients receiving any antibiotic therapy in combination with a loop diuretic.

HIGH CONCENTRATION OXYGEN INHALATION AS PROTECTION AGAINST NOISE INDUCED HEARING IMPAIRMENT

by David Lipscomb

A series of research projects was reviewed in which it was found that for both humans and chinchilla, inhalation of Carbogen (95% O₂, 5% CO₂) provided a degree of protection from intense sound stimulation. Regardless of whether the Carbogen inhalation occurred immediately before, during or immediately after noise exposure, the groups inhaling Carbogen experienced slightly less post-stimulatory TTS; the TTS recovery rate was accelerated; and, in animals, very

intense sound exposure resulted in less histologically observable damage for Carbogen treated subjects. It was concluded that Carbogen has a potentially useful application in cases of accidental noise exposure as post-stimulation treatment or in cases wherein adequate hearing protection cannot be guaranteed, pre-exposure inhalation of Carbogen can have a degree of protective value.

THE EFFECTS OF EARLY MIDDLE EAR PROBLEMS ON LATER LEARNING DEVELOPMENT REVISITED

by R. Ray Battin

The high incidence of early otitis media has focused attention on the long range effect on developmental auditory, language, learning skills. Pediatricians, Otolologists, Audiologists and Psychologists have documented delays in auditory processing and language-learning skills in youngsters with a history of early, chronic otitis media.

Since patients who consult with the above professionals are referred because of problems and thus may present a biased population, we decided to administer our comprehensive neuropsychological test battery to children with a positive middle ear history but who appeared not to have experienced behavior, speech, language or learning problems. Included among the tests were the Stanford Binet test of Intelligence, Illinois Test of Selective Attention, Attention subtests from the Detroit Test of Learning Abilities and the Templin-Darley Test of Articulation Development. Three children who had been followed otologically and audiologically from infancy because of chronic otitis media and who had documented, repeated, mild conductive hearing losses during the early years were administered the complete test battery. Two of the youngsters tested in the superior range of abilities, the third in the high average range. All three received a mean scaled score of 42 on the ITPA, the general population mean is 36. The means for the auditory-verbal subtest of the ITPA were 43, 46 and 42.

In summary, some children are susceptible to delay in auditory-language-learning skills when reoccurring otitis media is present during the early years while other children are not. It appears that the developing auditory-language-learning system can handle a stress such as a mild conductive hearing loss if other factors such as maximum environment, general health, familiar background, language background, neo-natal and natal history are positive. Additive stress factors may be the reason for variation in the punitive effect of middle ear disease during the formative years.

Identification and Implications of Visual Impairments for Hearing Impaired Persons: An Overview of a Project by Frank Caccamise, Donald D. Johnson, Nancy J. Kadunc, and Anita Rothblum

and
Identification of Visual Impairments in a Young Adult Deaf Population by Frank Caccamise, Lowell F. Hamilton, Donald D. Johnson, and Nancy J. Kadunc

These two papers provided an overview and initial results of a vision research project being conducted by the National Technical Institute for the Deaf (NTID), Rochester, New York. This project has three main objectives: 1) to determine the types and incidence of visual impairments among hearing-impaired college age students attending NTID; 2) to determine the most appropriate means for identifying these visual impairments; and 3) to assist in the providing of appropriate counselling relative to educational and career experiences for persons with both hearing loss and visual impairment.

Comparative vision tests results for NTID students were presented, with these comparisons involving: 1) personal questionnaires for students, 2) off-campus general health physicals, 3) off-campus ophthalmological examinations, 4) on-campus ophthalmological examinations, and 5) an on-campus visual screening program. This screening program includes the use of the Ortho-rater, Titmus Stereo Tests, and Iphihara Color Vision Test. Visual parameters assessed include acuity, refraction, binocular vision, color vision, and peripheral vision.

Based on the above comparisons, recommendations were made for revision of visual screening referral criteria for in-depth visual examination by a vision specialist. Further, recommendations were made for continued research involving comparisons of vision test results from off-campus general health physicals, on-campus visual screening, and on-campus ophthalmological examinations. This research should provide for additional information needed for visual impairment type and incidence data for NTID students (objective 1), and should further clarify the most appropriate means of identifying visual impairments among hearing-impaired persons (objective 2).

Also, plans have been made to conduct interviews with instructors in various technical areas and to conduct follow-up as indicated in order to provide information that will facilitate appropriate academic career counselling with persons having both hearing and visual impairments (objective 3).

Given the importance of vision to persons with hearing losses, it is recommended that: 1) an in-depth vision assessment be done routinely upon discovery of a hearing loss, and 2) re-assessment of visual functioning, as well as auditory functioning, be done periodically for all deaf and hard-of-hearing persons.

THE EAR AS IT WAS MEANT TO BE SEEN

by David Lipscomb

It is awesome to review the known capacity of the ear in dis-

tinguishing the presence of sound and in differentiating between a wide range of acoustic signals according to their meaningfulness. This immensely complex interactive group of specialized tissues did not simply spring instantaneously into being. Millions of years were spent using considerable experimentation and countless forms to achieve the highly sensitive and functional auditory mechanism.

A major theme throughout all we know about the development of hearing is the economy of creation:

- The ear takes up surprisingly little space—an economy which keeps the head no larger than necessary.

- Throughout the progressive stages of development, ear forms were provided which adequately served—but did not outperform the central nervous system, an economy which precluded expanding ability beyond the point of diminishing returns.

- Redundancy in auditory signals has been matched by redundancy inherent in auditory functions to economize on transfer of the information content of each stimulus.

- The developing inner ear took on an increasing role as an analyzer, leaving the central nervous system free to develop greater perceptual skills—an economy in neural organization.

- Providing the simplest structure which could accomplish a given task has been the policy in design of the auditory mechanism throughout the range of structure variation—an economy in tissue acquisition and usage.

- No special anatomical, biochemical, mechanical or architectural principles were invented to serve audition. The ear was designed utilizing existing principles according to the most economical method to employ each principle or set of principles.

In sum, the design and structure of the ear is so complete and so intelligent that it is an impossibility to conceive or to manufacture a system of the size and complexity of the ear which even comes close to the quality of performance we take for granted in our hearing sense.

WILLEFORD BATTERY IN CHILDREN

by R. Ray Battin

The ability to adequately integrate and decode auditorily is one of the problem areas observed in the learning disabled population. Audiologists are taking an increasingly greater interest in evaluating auditory dysfunction as it relates to learning problems. The Willeford battery was initially developed for diagnosing central auditory disorders in adults. It has been used with children with age norms established by Willeford in 1978. Audiologists using the test battery have reported a need to establish norms on their own population when using the battery with children and report lower scores for the Filter Speech and Binaural Fusion subtests.

Twelve children of normal or above intelligence with confirmed

learning problems in the auditory modality and twelve high achieving youngsters with no learning problems were administered the Willeford battery. The non-learning disabled children were able to perform the competing sentences and alternating speech subtests without difficulty. Performance on the Binaural Fusion and Filtered Speech tests fell below Willeford age norms. Further, age performance patterns were not observed. The obtained means for the Binaural Fusion test was 69% with a range of 35% through 95% for the low pass to the right ear and 51% with a range of 30% through 75% for the low pass to the left. The filtered speech test presented a mean of 52% (vs Willeford's 66%) with a range of 40% through 64% for the right ear and 46% (vs 66%) for the left. Three children (25%) had an ear difference which exceeded 10%.

Of the twelve learning disabled, the mean scores were below the normals on all four subtests. However, only three presented depressed scores on the competing sentences subtests and two children did poorly on the alternating speech test. Eight children did poorly on the filtered speech test while seven experienced difficulty with the Binaural Fusion subtest.

Two children who did poorly on the entire battery were placed on Ritalin and retested after six weeks on the medication. Both demonstrated significant improvement on all subtests suggesting attention focusing ability is a critical factor in handling the test task.

Due to the depressed scores experienced by our population, the test battery was administered to eight adults of varying linguistic backgrounds. It was found that individuals with a southern, bilingual or black language background had the same difficulty with the Binaural Fusion and Filtered Speech subtests as did our normal children.

In summary, the Filtered Speech and Binaural Fusion subtests appear to be heavily influenced by the linguistic background of the individual. Norms must be established for each clinic's population, and even then, the language background must be known before the results can be interpreted. Non-language based tests would appear to be the test of choice for evaluating brain stem function. Attention focusing skill also appears to be a critical factor in this battery. In fact, this may be what we are testing in the learning disabled child.

CENTRAL AUDITORY LESIONS

by Moe Bergman

Our work in this area is centered about a rehabilitation hospital for CNS pathology where we have applied tests of CNS dysfunction to two populations: those with cerebral cranial injury (CCI) and others with vascular accidents (CVA).

There were two major differences between these two groups

(continued on page 5)

Abstracts...

(continued from page 4)

The CCI patients suffered diffuse lesions, usually following severe head injuries, while the CVA patients were selected for our study on the basis of a single stroke, with a single focused lesion. Further, there were great age differences between the head trauma patients, most of whom were in their late teens or early twenties, while the CVA patients tended to bunch around age 60. It was evident that the testing must therefore be appropriate to the expected diffuseness or specificity of the lesions and be based upon norms established for the indicated age.

The results of our tests on the CCI patients both supported and deviated from the findings of Lynn and Gilroy's taken mostly from tumor cases. The competing sentences test quite consistently supported the existence of one-sided hemispheric lesions and the RASP test exposed brain stem involvement, where there was neurological evidence of the latter, although there were exceptions to the expected findings.

The results on the CVA cases, selected for lesions other than temporal lobe involvement, and generally free of associated aphasia, strongly indicated that extremely pathologic findings on the competing sentences test (100% on the ear ipsilateral to the central lesion and 0% on the contralateral ear) occurs consistently when the lesion is in the non-dominant (usually right) cerebral hemisphere, but the opposite tends to occur when the lesion is in the dominant hemisphere.

It is clear that results, on such tests of central lesions, are influenced by age, language background and even personality of the patient. Most importantly, the understanding of speech, under stressful listening conditions, depends upon systems of central function located in brain areas which are in different and often distant locations from each other.

While the present findings from the use of tests of CANS disorders are encouraging, we must recognize that the value of such tests in the search for topographic diagnosis is still uncertain.

THE DEVELOPMENT OF THE EAR

By David Lipscomb

In this workshop session, the earliest precursors to the auditory sense were discussed in detail to lay the groundwork for understanding more sophisticated, yet similar, structural entities contained in the mammalian inner ear. A review of the progressive steps in development of the ear ranged from aquatic auditory mechanisms, through amphibian, reptilian and avian species. The appearance of the first quasi-air conduction ears in early reptilian forms initiated a discussion of the relationship between jaw development and middle ear structure and function. Finally, the external ear, largely a structure for mammals was presented completing the remarkable chain of events leading to our human hearing.

BSER ABNORMALITIES IN MULTIPLE SCLEROSIS

by George E. Lynn

In 100 MS patients, abnormal

BSER recordings occurred in 6 or 29% of 21 cases of possible MS, 12 or 44% of 27 cases of probable MS, and in 40 or 77% of 52 cases of definite MS. The most significant abnormal BSER sign of brainstem dysfunction was increased interpeak latency between Waves I to III and III to V. Reduction in amplitudes, alteration in wave morphology and poor repeatability among trials were other aspects of abnormal responses frequently seen in MS. In about 2/3 of the probable and definite MS cases with abnormal BSER, findings indicated bilateral involvement of the brainstem. In most of the early or possible MS cases with abnormal BSER signs, the recordings suggested unilateral brainstem dysfunction. Abnormal BSER may be either focal, indicating involvement at some specific level of the auditory system anywhere from the auditory nerve to the mid-brain level, or may indicate diffuse involvement of the central auditory pathways of the brainstem. Changes in the BSER pattern over time were common and often quite marked during periods of exacerbation and remission of symptoms. Repeatability among trials often became very poor which was another abnormal feature of the BSER. Specific case material was shown to illustrate these findings.

BSER is very sensitive to the effects of MS lesions on the evoked electrical activity of the auditory system in the brainstem and a high percentage of MS patients will have abnormal tracings. BSER recordings are helpful in the diagnosis of MS, in differentiating level of involvement in the brainstem and are also very useful in monitoring the course of MS patients.

TEFLON-INTERPOSITION IN THE SURGERY OF OTOSPONGIOSIS

by J. Causse, J. B. Causse, J. Bel, R. Cezard & P. Michaux

Otology Clinic (Beziers-France) SUMMARY

This technique of stapedectomy, the "teflon-interposition," i.e. teflon piston against vein graft, was presented for the first time in Paris in 1963, fifteen years ago, and then at the International Congress held in Tokyo in 1965.

This technique is a combination of two SHEA's techniques: vein graft stapedectomy and teflon-piston. This combination seems to eliminate most of their drawbacks, chiefly perilymph fistula, thanks to a thin teflon-piston 0.6 mm against a living tissue graft, that is a vein. This technique is methodically described and each of the four operative steps are first illustrated then followed by the surgical application.

Then the method is applied to each of the footplate anatomical types most usually encountered, i.e. more or less encroached: first thin footplates, then "biscuit" footplates, finally, obliterated otospongiosis. Each case is first illustrated by an animated cartoon, then by surgical operating.

The audiometric results, generally good, are shown by the presentation of an extreme, but typical, case of Carhart's notch disappearance. The way of formation of this notch is described in relation to this case which shows its disappearance through a flattening of the curve. The value of the functional results

seems due to the use of a living tissue graft, preferably the vein.

BSER IN LOCALIZATION OF POSTERIOR FOSSA LESIONS

by George E. Lynn

The major points reported in this paper were:

1. In the normal BSER recordings obtained at 75 and 85 dB HL (11 clicks per second), the important components of the response are the absolute latency of Wave I and the I to III and III to V interpeak latencies. Amplitudes, wave morphology and repeatability among trials are other important aspects of the response pattern.

2. In all 21 cases of confirmed extra-axial cerebello-pontine angle (CPA) lesions involving the auditory nerve, Wave I was abnormal in the recordings from the ear ipsilateral to the affected side. In 8 patients with large CPA lesions displacing the brainstem, the III to V interwave latency in the contralateral ear recordings was also abnormal.

3. BSER in patients with intra-axial pontine lesions revealed a normal Wave I when the auditory nerve was not involved. The ipsilateral I to III inter-wave latency was abnormal in patients with lesions localized primarily at the ponto-medullary junction of the brainstem or the caudal pons. Voltages and wave form of components above Wave I were also abnormal. In lesions localized to the mid and rostral portions of the pons, the I to III interwave latency was normal, and the III to V latency abnormal in the contralateral ear recordings. Diffuse and bilateral pontine lesions affected the I to III and III to V interpeak latencies, amplitudes and wave form on both sides.

4. Lesions at the mid-brain level were shown to affect the latency, amplitude and/or wave morphology of Wave V on one or both sides depending on the extent of involvement. BSER could not differentiate intra and extra-axial brainstem lesions at this level.

BSER is exquisitely sensitive to lesions of the posterior fossa. All components of the response pattern are important if one wishes to differentiate intra and extra-axial lesions, the level of the lesion within the brainstem and the side primarily involved. Interesting cases were presented to illustrate the localizing value of BSER in neurological disorders.

MEDICAL MANAGEMENT OF OTOSPONGIOSIS AND NaF THERAPY

by J. and J.B. Causse
Otology Clinic (Beziers-France)

I. PROBLEMS OF POST-OPERATIVE THERAPY

Among the abundant literature dealing with otosclerosis surgery, very rare are the papers mentioning postoperative care. In fact the problems of the stapedial fixation can be easily cured thanks to a sure diagnosis, a safe functional technique, based on a supple transmission to an elastic and valuable living tissue graft, and a surgeon's technical skill. But much more difficult to be solved are cochlear problems following stapedectomies.

We think that medical surveillance after stapedectomy is as important as the operation itself. We are used to saying "half and half."

As the responses of an ear to a

stapedectomy are now better understood as we now have the means to combat the main causes of cochlear drop, we believe that all stapedectomized patients should be carefully surveyed by systematic audiometric check-ups to be able to detect a cochlear failure early, and then to treat the cochlear drop vigorously by all means available in each case.

II. BASIC OF POST-OPERATIVE THERAPY

Postoperative therapy is easy to justify:

1/ Changes in perilymph pressure and operative trauma, even if slight, cause hair cells to suffer from a shortage of oxygen and glycogen, as well as for any sensorial cell in the body. Perilymphatic oxygen tension decreasing causes tinnitus and cochlear drop in the area of the cochlea, as well as dizziness or vertigos are the labyrinthine reaction to this defect. Moreover surgical micro-trauma, enhanced by intraoperative bleeding, has a side-effect on the vascular permeability. The escape of serum from the capillaries and the toxic action of serotonin from the platelets induces hydrops within the labyrinth, while sludging of red cells within the capillaries slows the circulation and promotes anoxia with further capillary damage and temporary or permanent hair cell trouble. Last of all, noise exposure at this early postoperative period increases hair cells oxygen consumption and is especially harmful at this time (1). The only means to combat the shortage of perilymph oxygen is to increase the intralabyrinthine blood flow to bring oxygen to the hair cells through the stria vascularis, inhalation of carbon dioxide-oxygen being less efficient than vaso-active drugs.

2/ Labyrinth blood supply is given by the internal auditory artery, which is an end-artery, originated in the vertebral basilar artery through the posterior cerebellar artery. Thus cochlear blood flow consists of 9/10th vertebral artery blood and 1/10th carotid artery blood, that is to say that its origin is mainly vertebral, consequently of peripheral value.

3/ Cochlea and posterior labyrinth are contained in the same bony shell, supplied by the same internal auditory artery and bathed in the same fluids. Consequently, vaso-active drugs acting on this posterior labyrinth, for instance in Meniere's disease, must act efficiently on the cochlea. Moreover the membranous structures are almost similar, but with their peculiar responses: hearing loss and tinnitus for the cochlea, vertigos for the posterior labyrinth.

Such reasons seem to be evident from the anatomical, physiological and pathological point of view. But a great discrepancy appears between the widespread clinical use of so-called "vaso-dilator" drugs and the experimental results on animals. These divergent opinions are not surprising, for the cochlear blood vessels react differently under normal and pathological circumstances and the experimental conditions in animals cannot be identical to the pathological ones in humans after stapedectomy. Moreover experiments on animals were always done by continuous intravenous perfusions, while for the last twenty years, we have been publishing that in clinical practice on patients discontinuous intravein-

ous injections only are effective. One should not confuse an active capillary plasticity and a passive one. It is obvious that intra-cochlear bony canaliculi arteriolae have no motivity, but also that any vaso-motivity acting above them, will consequently act on these passive capillaries. This passive plasticity easily explains the action of vaso-active drugs on undilatable terminal bone arteriolae, and thus on stria vascularis, but only by discontinuous intravenous injections.

As a matter of fact, it seems that the vasodilation in the cochlea does not necessarily cause an increase in cochlear blood flow because of the associated hypotension caused by perfusion. For this reason, we have always recommended discontinuous intravenous injections repeated 3 or 4 times a day on patient always in decubitus for at least half an hour.

Last of all, if opinions are divergent on the clinical action of same vasodilators on the cochlea, physiologic and pharmacologic studies of the autosomic control of cochlear blood flow, have produced conflicting evidence and the studies of agents whose effect on cochlear blood vessels is not mediated directly through the adrenergic and cholinergic nervous systems, have also produced conflicting observations, according to the methods used. But it seems that some drugs have earned universal approval of clinicians and researchers (2, 3, 4): those are Papaverine, considered as the safest, the most effective and the best tolerated. Histamine and Betahistine, intravenous injections of hypertonic glucose solutions, and inhalations of 10% carbon dioxide with 90% oxygen. As for the Nicotinic acid, SUGA and SNOW (5, 6 and 7) stated that it has no effect on cochlear blood flow, whereas OKA (8) reported that intramuscular injections of niacin dilated cochlear vessels in the guinea-pig. The choice of drugs acting on cochlea blood vessels remains wide.

III. IMMEDIATE POST-OPERATIVE CARE

The early postoperative period is critical in any stapedectomy requiring daily bone-conduction audiograms and Weber test from the 5th postoperative day (and sometimes before) to detect a possible cochlear drop immediately. This condition is prerequisite in order to obtain an effective action of vaso-active drugs, which generally become inactive 36 hours after the cochlear drop. The drop in cochlear response is evidenced by a decline in bone conduction levels greater for the upper tone range, a shift of pure tone and speech Weber test to the better ear (operated on or not) and a distortion with impaired discrimination in speech audiometry. Tinnitus and vertigo are very often absent at this early period and never should be waited for. The practice of deferring the first audiogram to the third or fourth week after stapedectomy eliminates any possibility of reversing cochlear disorders.

The set of drugs to improve cochlear blood flow, thus to afford oxygen and glycogen to the hair cells and to combat the labyrinthine reaction, is made of:

a/ Vasodilators: the first used is the old nicotinic acid, always given by repeated intravenous in-

At The International Symposium on Otitis Media

Jan Zarnoch & Sylvan Stool Discoing after meeting. Stool presented School for the Deaf Study.

Imre Friedmann discussed the Pathology of Otitis Media. He is our English correspondent.

Earl Harford and Fred Bess enjoying Columbus' best. Both presented papers at the Symposium.

Jennifer Harford was an eager listener.

Jerry Klein, Boston presented an excellent epidemiological report on Otitis Media.

Paula Menyuk, Boston gave an impressive discussion of language and hearing.

John Ferraro & Jerry Northern. Northern participated in the Impedance Screening Debate.

Margareta Moller and Jim Jerger. Moller headed group on O.M. related to Screening & Identification. Jerger chaired Sequelae program.

Abstracts...

(continued from page 5)

jections made intermittently three to five times a day, and never by continuous perfusions. This method "massages" the impaired intra-labyrinthine circulation, brings oxygen to the hair cells through the stria vascularis and promotes recovery of cochlear function. It should begin 36 hours after the operation (to avoid increased postoperative bleeding) and last till the 20th day in decreasing doses.

The second vaso-active drug that we use, is **Papaverine**, which has earned universal approval of clinicians and researchers. It increases cochlear blood flow considerably and decreases the systematic blood pressure only slightly. Moreover it relaxes smooth muscles of large blood vessels, particularly during vagospasm. Its effects are relatively long lasting. It appears to be the drug of choice.

The third vasodilator is **Histamine** (and Betahistine) given by progressive intravenous dilute dosage, as in Meniere's disease. Many authors, chiefly G. E. SHAMBAUGH, are convinced that this method is the best, but its action on the blood flow of the cochlea and of the brain is too often neutralized by a fall in arterial blood pressure.

Inhalations of 10 per cent carbon dioxide and 90 per cent oxygen increase cochlear blood flow with little changes in systemic blood pressure. GANDIN (9) recommends them to combat hair cell anoxia. G. E. SHAMBAUGH and John SHEA are using 5 per cent CO₂ and 95 per cent O₂ at 6 liters/minute, for 5 minutes every hour, for the first three postoperative days.

There are many newer drugs, but more expensive and often less active, such as pyridyl carbinol (RONICOL) and Naftidrofuryl (PRAXILENE).

Additional therapy includes:
—small doses of **Heparin Sodium** (2500 units) by subcutaneous injection twice or three times daily after the third postoperative day (Not before to avoid increased bleeding in the middle ear). At these very small doses, Heparin helps vasodilators action, tends to resorb exudates and prevents phlebitis.

—**Steroids**, added to usual antibiotics, are helpful because of their anti-inflammatory effect on the middle ear and tubal function.

—**Hypertonic glucose solution**, 20 cc, given three times a day by intravenous injections in case of Cochlear drop, dizziness or tinnitus. It increases cochlear blood flow and brings glycogen and oxygen to hair cells.

—**Hydrocortison Hemi-succinate** is the most recent. Given by intravenous injection of 500 mgr., three times a day, rapidly decreased to twice and finally once a day, and added to increased doses of vasodilators and to hypertonic glucose solution, it combats cochlear drop with effectiveness, on condition that this set of 3 drugs is administered as soon as possible before the 36th hour.

IV. MAINTENANCE THERAPY

It consists of drugs administered for varying length of time depending on their type and their desired goal.

1/ **MILD ORAL VASODILATORS**, such as dihydroergotamine mesylat (Hydergin),

dihydroergotamine (Dihydroergotamine), papaverine, pyridyl-carbinol (Ronicol), naftidrofuryl (Praxilene).

Large doses, even for months, must be avoided, for they favour passive congestion and thus promote enzymatic activity. But slight doses must be given for months, and even for years, for cardio-vascular patients.

Thanks to this maintenance therapy, following the immediate postoperative treatment, bone conduction levels generally increase over the preoperative ones. But we must take into account the disappearance of CARHART's notch thanks to the stapedectomy and the difficulties in measuring the precise cochlear reserve by bone conduction.

2/ **SODIUM FLUORIDE THERAPY** is given to act on the cochlear otospongiotic impairment. In the first lecture on the enzymology of otospongiosis, we have studied the mechanism of sensorineural loss in pure cochlear otospongiosis and in the stapedial fixation combined with a cochlear involvement.

The mechanism of NaF therapy is an enzymatic action on the first phase of destruction, the most important in regard to the bony foci and inner ear fluids. NaF seems to increase the antitrypsin activity reactivated through the alpha 2 macroglobulin and thus to balance tryptic activity which has a toxic action on the hair cells and destroys the collagen fibrils of the bony otic capsule, chiefly in the stapedial area.

The effect of fluoride medication is twofold: an early effect of fluorides, very efficient on the microfoci expelling the cytotoxic enzymes into the labyrinthine fluids, in retarding or arresting the sensorineural deterioration in otospongiosis; a less evident, more gradual and long-term effect in reducing the bone-remodelling activity of the focus.

Objective evidence of the favourable effect of fluorides on otospongiotic foci is afforded by: 1) repeated polytomographic studies (1); 2) extensive statistical analysis of large numbers of treated and untreated patients (we have available computerized data on 10,441 cases with long-term results on operated or unoperated otospongiotic patients over a 10 year period with various NaF doses); 3) comparative dosages of trypsin concentration in perilymph before and after NaF therapy. (10,11). In this study, undertaken with Jose URIEL and Josette BERGES, the results clearly show that the trypsin amount significantly decreases in about 66% of patients with moderate doses of NaF, generally 45 mg a day, the results having been corrected in relation to control series.

Optimum dosage is determined by the concept that, as NaF acts by presence more than by weight (as any enzymogenesis regulator does), we must reach an **action threshold**, below which it does not act and beyond which its activity does not increase in relation to the doses. Clinical trials with various doses from 3 to 60mgr daily, led us to the notion that: 1. **very small doses** ranging from 3mg to 6mg daily are sufficient to act on pure cochlear otospongiosis, less active than the stapedial fixation from the enzymatic point of view; 2. on the contrary, doses must be **greater**, ranging from 15mg to 45mg daily for stapedial fixations with a cochlear compo-

ent, in which an important enzymatic activity is needed to cause both bone rebuilding of the niche and spreading of hydrolytic enzymes into the labyrinthine fluids. Larger doses of 60mg to 120mg daily did not appear to give any better results, for 120mg daily did not appear to give any better results, for NaF has a **double action** according to the doses (JOWSEY) (12): NaF doses of 60mg daily or more cause a pseudo-haversian rebuilding resulting in the formation of a very fragile new bone, whereas doses of 45mg daily or less do not increase bone formation and act only on enzymatic activity. For this reason, we always give our patients **moderate doses** of NaF, ranging from 15mg to 45mg daily, to stop cochlear deterioration without increasing stapedial fixation. Therefore, we do not need to add vitamin D and Calcium supplement to prevent formation of abnormal bone.

Starting from this data, we generally prescribe:

1/ **for adults:**

—**60mg daily**, five days a week, only for advanced otospongiosis with a very active cochlear component, and for the cases on which less important doses have not acted; and always for a very short period of time, 6 to 8 months at the very most.

—**45mg daily**, continued for 2 years, as a starting postoperative treatment for all surgical cases with a progressive cochlear component.

—**30mg daily**; for 2 years also, as a maintenance dose following the previous one, if the yearly audiometric surveillance shows a good stability of bone conduction levels;

—**15mg daily** as a lasting dose for years, till inactivation of the otospongiotic foci proved by bone conduction stability for 2 to 4 years;

—**3mg to 6 mg daily**, continued for years, for pure cochlear otospongiosis as well as preoperative therapy for stapedial otospongiosis with an important progressive cochlear deterioration.

2/ **for children**, we give much more moderate doses, ranging from 1.5mg to 10mg daily, to avoid possible stunting of the growth by a too early calcification of the long bone matrix.

Surveillance of this lasting NaF therapy must be three-fold: 1/ audiometric check-up once a year in order to check the stability or the progression of the bone conduction levels; 2/ polytomography X-ray investigation to verify NaF's action on the bony otic capsule every year; 3/ X-ray investigations of the long bones, lumbar column and pelvis, every two years to detect possible fluorosis.

There is **no toxicity** at these moderate doses, chiefly if we consider that part of NaF is destroyed in the digestive tract by tricalcic phosphate and calcium carbonate. Doses that we prescribe, are below the therapeutic security levels and thus far below toxic doses. What is more, we have never seen any fluorosis on more than 10,000 cases surveyed by computer. We must only be careful with patients suffering

Tolerance is generally good and gastric intolerance very rare, if NaF is prescribed in enteric coated tablets. This is the only means to avoid NaF dissociation by gastric acids, resulting in production of very harmful hydrofluoric acid provoking severe gastric troubles, and in suppression of

NaF activity. We must only be careful with patients suffering from a chronic nephritis, as impaired excretion of NaF might lead to toxic concentrations in the blood. On the contrary, the moderate doses are compatible with cardiovascular diseases, for the sodium doses correspond to 8.20mg per 15mg NaF enteric coated capsule, that is 24.60mg for 45mg NaF daily. Lactose generally used as excipient, must be avoided for patients suffering from diabetes.

The **functional results** yielded by our computerized data on 10,441 cases with a follow-up ranging from 3 months to 10 years, are favourable.

But "**favourable results**" only means arrest of cochlear deterioration in cases having a progressive cochlear component because NaF acts only as a stabilization factor, and so it cannot improve hearing, except in children. Moreover a follow-up of one or two years at least is indispensable to have a sure approach to the problem, because the otospongiotic disease generally develops by progressive steps, separated by inactive periods due to spontaneous balance enzyme-antienzyme. For this reason, we have always **corrected** the functional results in relation to equivalent control series, taking into account the 25% **spontaneously non progressive otospongiosis**, operated or unoperated.

We have summarized our main computerized data in two tables (Tab. I and II). **Table 1** shows higher doses in surgical cases than in medical ones, as already reported. **Table II** proves that the various doses have been correctly established to pass slightly over NaF action threshold since percentages in relation to different doses related to enzymatic activity, are similar for medical cases and surgical ones, that is 66.41% for medical cases and 67.52% for surgical cases.

As for its **action on stapedial fixation**, NaF seems to slow it in some cases, but it is very difficult to evaluate. It is obvious that NaF action cannot release stapedial fixation for moderate doses of 45mg or less act only on the first otospongiotic phase of lysis and thus only prevent the second phase of pseudo-haversian rebuilding. Larger doses increase the stapedial fixation, as already related.

Fluoride action on vestibular function clearly appears. Patients generally show less vertigo or dizziness after some months of NaF therapy, as well as less tinnitus for cochlear function. Moreover we experienced a series of 224 comparative studies by means of torsion swing test ENG recording, before and after NaF therapy on operated or unoperated otospongiotic patients: the more or less irritative type tracing, usual in otospongiotic patients, tends to become less irritative or even normal in almost 70% of operated ears and 60% of unoperated ears in relation to the control series after 6 months or more of NaF therapy.

These results have been recently confirmed by an important paper of Thane CODY and Hillier BAKER (13), who stated that the administration of a combination of calcium gluconate, sodium fluoride and vitamin D controlled vestibular symptoms in a high percentage of patients who had vestibular symptoms, and stopped the deterioration in hear-

ing in patients who had cochlear deterioration. The action of NaF on vestibular symptoms was also supported by COLE and FUNKHOUSER in 1972. (14)

V. CONCLUSION

NaF is a logical therapy to combat cochlear deterioration, for which there was no therapy before. It is till now the only drug which can slow or arrest the activity of otospongiotic microfoci in more than half the operated or unoperated otospongiotic patients. Moreover, it controls cochlear and vestibular symptoms in a high percentage of patients who had tinnitus and/or vertigos. Its action seems safe and effective at the moderate doses that we recommend.

SUMMARY

The authors wonder why the amazing progress made in the past half-century in the diagnosis and surgical treatment of stapedial otosclerosis has not been supported by postoperative care. Presently, better knowledge of cochlear and vestibular pathology and of the enzymatic mechanism of otospongiosis, allows them to prevent a high percentage of cochlear deterioration after stapedectomy thanks to a close audiometric surveillance and to adapted postoperative medical therapy.

They state the basis of the postoperative care and review the numerous drugs to be applied in the immediate postoperative period, and later for a more or less long time. The effectiveness of each drug is studied, first vasodilators, - second enzymogenesis regulator, i.e. NaF. They emphasize NaF therapy and give all necessary indication on its action, doses, tolerance, contraindications and side-effects.

They conclude in stating that the medical management of the disease is valuable and the postoperative therapy effective in a high percentage of cases. As for NaF, it seems to be logical, safe and effective at the doses they recommend.

Speech Pathologists Have Laws Too

With the spate of pseudo-scientific adages—such as Murphy's Law, Peter Principle, Jennings Corollary etc.—Corti's Organ is happy to announce a soothsayer of great magnitude among our own colleagues. And a speech pathologist, no less. He is Gordon Schuckers of Louisiana State University Medical Center, Shreveport, who has come up with what we consider the most telling of all such profound exhortations. Herewith is printed the latest brain child of this author, lecturer, poet, philosopher, and great human being:

GORDON'S LAWS

- I. You can't make me angry without my permission.
- II. I myself personally am redundant, etc., etc., etc.
- III. The problem with being assertive is—if you're dumb it really shows.

IV. Convicts and convictions are similar: each involves a locked-up person.

V. There are performers and critics—fortunately for the latter there are the former.

VI. Everything in your body is ultimately connected to your brain—unless you have a Ph.D.

VII. Anxiety is the price you pay for being a racehorse instead of a cow.

VIII. The difference between arrogance and modesty is ability.

IX. The object of work should be doing—not viewing.

X. Bases become biases when you add an I.

Berger Holds Hearing Aid Prescription Workshop

Kent State University is sponsoring a one-day workshop on "Hearing Aid Prescription" on October 20, 1979.

Speakers will be Kenneth W. Berger, Ph.D., Mead C. Killion, Ph.D., Joseph P. Millin, Ph.D., and Eric N. Hagberg, M.A.

Registration fee is \$35.00, including lunch and workshop materials. Registration is limited. Contact: Kenneth W. Berger, Ph.D., Speech and Hearing Clinic, Kent State University, Kent, Ohio 44242. Telephone (216) 672-2672.

Middle Ear Effusion Poses Problems

One of the highest-powered meetings in the country is the Columbus Conference on Recent Advances in Middle Ear Effusion, held this year on May 9-11 at the Ohio State University College of Medicine. David Lim, Charles Bluestone and Ben Senturia were the committee putting together an outstanding number of otitis media papers from throughout the world.

Honored at the meeting was Sven Ingelstedt of Sweden, whose studies on middle ear pressure and gas absorption remain classics in the field. A large group of his Swedish associates participated in the meeting, as well as lecturers from Japan, Israel, Germany, Austria, England, France, Denmark, New Zealand, Finland and Italy.

This brilliant assemblage was not as well attended as it deserved, due possibly to the onset of a financial recession in this country—or possibly to the flood of

meetings that has engulfed us this year. For any one interested in the ear the Columbus meeting was a must on the schedule.

An awesome amount of research was presented by the group from the Pittsburgh Children's Hospital. This group explored eustachian tube and middle ear function in great depth.

A departure from purely medical topics was the introduction of a section on the educational sequelae of otitis media. Two excellent papers were presented by Paula Menyuk and Frances Horowitz on the effect on psycholinguistic skills of early otitis media, pointing to the need for regional studies which will provide information about both the short and long-term effects of the disease on language development that can be used in planning educational intervention. The interest in this non-medical phase of the sequelae of otitis media is a signal advancement in the field.

BOOK REPORT

Acoustic Tumors edited by William F. House and Charles M. Luetje is written in two volumes. This is a report on the first volume, **Diagnosis**. The second volume on **Management** will be reported in the next issue.

The book is a report of five hundred patients with unilateral acoustic neuromas operated by members of the Otologic Medical Group in Los Angeles between 1968 and 1975. There were 275 females and 225 males ranging from age 9 to 76 with equal occurrence on right and left sides.

The history of acoustic tumor surgery is discussed with reference to the work of Cushing from 1900-1917, the "Dandy Era" from 1917-1961, and the present work pioneered by House.

The second section on pathology suggests that tumors arise from excessive schwann cell proliferation at the schwann-glia junction near the porus acousticus internus. The anatomy of the anterior-inferior cerebellar artery (AICA) is discussed in relationship to the cerebellar pontine angle tumors as well as the loop of AICA often found within the internal auditory canal (40%) and usually giving

rise to the internal auditory artery (80%).

Tumor symptoms are categorized into three types: changes related to the internal auditory meatus (VII, VIII), changes related to the CPA (V, VI, IX, X, XI, and cerebellum) and distant effects due to internal hydrocephalus and increased intracranial pressure.

The Antoni A and B light microscopic pathologic configurations is well illustrated. In bilateral, or Von Recklinghausen's cases, the nerve fibers are more intact and not compressed to one side as much, but separated by growing tumor.

In section III, selected case histories are presented and the neuro-otologic evaluations detailed. The most common presenting symptom was unilateral hearing loss usually associated with tinnitus. Vestibular symptoms were present in 69%. The audiogram usually revealed a high tone loss (65%). Tone decay was complete or partial in only 77%. The acoustic reflex was absent or decayed in 80%. A reduced response with electronystagmography was found in 82% of cases. Petrous

pyramid x-rays were positive in over 90%.

Brainstem electric response audiometry (BERA) was accurate in detecting tumors in 96% of cases with an 8% false positive rate.

Routine evaluation has evolved to include audiogram with speech discrimination, petrous pyramid x-rays, ENG and acoustic reflex test with the BERA often replacing the ENG and acoustic reflex as a screening test. Computerized cranial tomography (CAT or EMI scan) is followed by a small dose Pantograph polytome study if the scan is negative. The CAT scan is helpful in estimating tumor size, differential diagnosis, and presence of hydrocephalus, although scanning was reliable only with tumors measuring 2.5 cm or larger.

The radiographic techniques are well discussed with excellent illustrations included.

(The second volume on Management will be reviewed in the next issue of Corti's Organ).

Audiology Congress Meets In Krakow In 1980

The International Audiology Society will hold its 15th biennial Congress in historic Krakow, Poland on September 2-6, 1980. Plenary sessions are being planned on the following topics:

- I. Evaluation of Auditory Function after Surgical Procedure.
- II. Etiologic Factors in Sensorineural Hearing Loss.
- III. Paediaudiology.

In addition to these round table sessions, contributed papers are invited on audiological topics. Applications may be sent to: Dr.

Andrzej R. Halama, Kopernika 23a, 31-501 Krakow, Poland.

A group charter flight is being planned for this Congress and will be announced in the next issue of Corti's Organ. Krakow will be a fascinating city to tour. It is an ancient walled city with a 13th century castle to visit. Scientists will be interested in seeing Copernicus' laboratory with his original instruments, located in the ancient University courtyard buildings.

AAS members will want to

attend their sister society's meeting, particularly as the I.A.S. had as one of its founders Aram Glorig, our own AAS founder. Ray Carhart also was one of the organizing members of the IAS, as were others like Ira Hirsh, Hallowell Davis and Richard Silverman.

The I.A.S. publishes *Audiology*, a highly scientific journal tightly edited by Dr. E. Konig of Basel, Switzerland. The editorial board includes Aram Glorig, Ronald Hinchcliff (U.K.), and Pierre Tremque (France).

Speech Conference Scheduled

The Ph.D. Program in Speech and Hearing Sciences of the City University of New York Graduate School is sponsoring a three-day conference on the "Speech of the Deaf: Research, Training and Personnel Preparation" from October 31 through November 2, 1979. The purpose of the Conference is threefold: (i) to provide in-depth coverage of recent research on the speech of the deaf, (ii) to explore how the results of this research can be used in improving speech training methods, and (iii) to examine the implications of the above on personnel preparation.

The Conference should be of interest and relevance to teachers of the deaf, audiologists, speech pathologists, university faculty and researchers in the area. The Conference is designed to facilitate a dialogue among the various contributors and between the audience and the contributors.

The practical application of research findings will be emphasized by the participation of experienced teachers, clinicians and researchers in "round table" discussions.

Participants will include leading figures in the field from the United States, Canada and

Europe. A sampling of topic areas include: recent research of the speech production and reception skills of the deaf; developmental aspects of phonological production and reception in deaf and normal hearing children; assessment procedures; sensory aids for speech training; recent developments in speech training strategies; and needs and approaches to personnel preparation.

For more information contact Irving Hochberg, Harry Levitt or Mary Joe Osberger, Ph.D. Program in Speech and Hearing Sciences, Graduate School, CUNY, 33 W. 42nd Street, N.Y., N.Y. 10036. 212-790-4367.

Blood Flow Biofeedback Training

Whenever a person becomes excited, afraid or anxious, the blood vessels feeding the skin and extremities (hands and feet) constrict. At the same time, the reverse occurs for the large blood vessels feeding the somatic muscles of the legs and arms. Dilation and constriction of specific blood vessels is an important part of the flight or fight reaction discussed earlier which increases the chance of an organism surviving physical confrontation and trauma. Vasodilation of the large vessels feeding the somatic muscle allow more oxygenated blood and nutrients to be fed to the muscles so that the organism will be stronger. Vasoconstriction of the vessels feeding the extremities and skin limits the loss of blood due to the skin being cut or broken. At the same time, sweating of the extremities increases. Decreasing blood flow to any part of the body will cause the temperature of that particular part to decrease. That is why people who are anxious or frightened have cold, sweaty hands and/or sometimes break out in a cold sweat.

An instrument that measures either or both the changes in temperature or opacity due to blood flow and converts these changes to a signal that allows the patient to be aware of his blood flow constitutes a blood flow biofeedback unit. Peripheral blood flow is usually measured in two ways:

1. by measuring the small temperature changes that occur as blood flow increases or decreases,
2. by using a plethysmometer that records changes in opacity of the tissue that occurs as blood flow changes.

The plethysmometer is sensitive to the blood flow because the more the blood flows the darker or more opaque (less light can pass through the tissue) is the tissue. The biofeedback signal can be in a variety of modalities. For example, a tone can be fed back to the patient that varies in frequency as the opacity or temperature changes. The higher the tone pitch, the more the blood flow.

Researchers (Snyder and Noble, 1968, and Simpson, 1972) have reported that patients can learn to voluntarily control vasoconstriction and dilation in their extremities.

Biofeedback training in which the amount of blood flow change is monitored and converted into a signal that varies proportionately to the blood flow enables a patient to gain control over his abnormal vasoconstriction or dilation.

Researchers have consistently found that most motivated people have the potential to voluntarily produce localized change in blood flow (Hadfield, 1920, Schultz, 1926, Menzies, 1941, and Varano, et al, 1965). Menzies and Schwartz, 1941, reported that individuals can cause vasodilation (increase in temperature) in an extremity by just recalling past experiences concerning warmth (Roberts, Kewman and MacDonald, 1973, and Barber, 1974). Conversely, some individuals could cause vasoconstriction (decrease in temperature) in an extremity by recalling experiences that caused the limb to become cooler. The human imagination can certainly alter our bodily functioning.

MIGRAINE HEADACHES

Migraine headaches have been

described as a human malady since the beginning of medical history. They usually begin in adolescence but can occur at any time. Migraines are characterized by a variety of symptoms including general irritability and nausea, photophobia (intolerance to light), vomiting, constipation or diarrhea. They often are precipitated by emotional conflicts or situational stress. Migraines may begin in a variety of ways. Sometimes the patient experiences scotomata (a spot within the visual field), hemianopia (loss of vision for one-half the usual field), unilateral parasthesia (abnormal sensations) and various speech disorders (Wolff, 1946).

Both tension and migraine headaches are characterized by an increase in blood flow to the head. The cranial arteries and blood vessels throughout the head dilate (Wolff, 1963). Migraine sufferers frequently report that they have cold hands and hot foreheads. Vasoconstriction occurs in the extremities which decreases the blood flow, that in turn decreases the temperature. The reverse occurs in the forehead, vasodilation increases blood flow, which in turn increases the temperature. The head pain occurs when blood is being pumped through distended or the dilated blood vessels. Migraine and tension headaches are qualitatively different disorders. Tension headache sufferers have usually higher frontalis muscle tension and lower forehead temperatures than migraine victims. They also respond differently to different treatment procedures. EMG feedback training has been shown to be approximately 70% effective in alleviating the discomfort of tension headaches. Whereas, migraine headaches are more successfully treated by blood flow feedback training (Sargent, Green and Walters, 1973; Wickramasekera, 1972, 1973, and Budzynski, et al 1973).

The abnormal vasoconstriction and dilation that characterizes migraine headaches is governed by the autonomic nervous system that is not normally under our voluntary control. Any method that would enable a migraine sufferer to voluntarily control the abnormal blood vessel activity can be of therapeutic value. Various techniques that cause vasoconstriction in the head and/or vasodilation in the extremities have been used in combination and in some cases alone, to successfully treat migraines. However, the best results have been obtained by using a combination of approaches. To date, no one method seems to be the best. Migraine headaches, like most stress-related problems, are best dealt with by using a combination of therapeutic programs that are tailor-made to suit the particular needs of the patient. The same psychosomatic or stress-related problem can have many different causes and, therefore, different types of treatment may be necessary.

Successful treatment of migraine headaches by biofeedback techniques alone and in combination with other techniques, has been reported by Sargent,

Green and Walters, 1973, Peper, 1973, Budzynski, 1973, and Wickramasekera, 1973.

The first procedure outlined was designed and validated by Sargent, Green and Walters, 1973, who were the first to report the use of blood flow feedback training to treat migraine headaches. Their training procedures, called autogenic-feedback training, combines temperature feedback training and autogenic suggestions (Schultz and Luthe, 1959).

Autogenic training was developed by Schultz and Luthe (1959) to induce relaxation in overly anxious or tense patients. The method involves the patient repeating to himself suggestions of heaviness and warmth. The goal of autogenic training and most relaxation training procedures is to increase parasympathetic arousal (autonomic nervous system activity that accompanies emotional arousal). As the patient relaxes, vasodilation in the extremities occurs and blood flow increases.

Schultz and Luthe present evidence to indicate that the suggestion of heaviness induces muscle relaxation and the suggestions of warmth cause vasodilation in the extremities. It makes sense from psychological standpoint to induce general relaxation in any patient that has problems involving decreased blood flow to the extremities. The autonomic system, when a person is relaxed, causes the blood flow to the extremities to increase. Migraine sufferers have been shown to respond favorably to relaxation training alone (Mitchell and Mitchell, 1971). Relaxation training in conjunction with blood flow training appears to be an unbeatable combination.

The Sargent, Green and Walters, 1973, autogenic-feedback training is as follows:

The patient first receives instructions in the use of the temperature feedback unit. A difference in temperature was recorded between the right index finger and the forehead. The patient can receive feedback concerning the temperature from observing the temperature gauge or the feedback tone. The clinician instructs the patient to passively attend to the tone or gauge and keep his hand temperature increasing. The patient is then given a sheet containing the autogenic phrases that he is to recite to himself. The first group concerns general relaxation of the whole body, as follows:

"I feel quiet... I am beginning to feel quite relaxed... My feet feel heavy and relaxed... My ankles, my knees and my hips feel heavy, relaxed and comfortable... My solar plexus and the whole central portion of my body feel relaxed and quiet... My hands, my arms, and my shoulders feel heavy, relaxed and comfortable... My neck, my jaws and my forehead feel relaxed... They feel comfortable and smooth... My whole body feels quiet, heavy, comfortable and relaxed."

After the patient learns the phrases, he is told to focus his attention on the temperature trainer. If he has relaxed, the temperature of his hand should

have increased at least slightly. Most people initially show some change. Next, he is given the next group of autogenic phrases that are designed to teach the patient to increase the blood flow specifically in his hands, as follows:

"I feel quite relaxed... My arms and hands are heavy and warm... I feel quite quiet... My whole body is relaxed and my hands are warm, relaxed and warm. Warmth is flowing into my hands, they are warm... warm."

Through repeated training, the patient learns to manipulate by his own volition the feelings in his extremities that are concomitant with vasodilation. As vasodilation occurs in his hand, vasoconstriction occurs in the head, and the migraine subsides.

Wickramasekera, 1973, used EMG feedback training as previously described by Budzynski, Stoyva and Adler, 1973, with migraine headache sufferers and then used temperature feedback training. He found that following the EMG feedback training using the frontalis muscle, the patients reported only a slight reduction in their headache pain. However, they still had as many headaches as before. Following the EMG training, he trained both patients to increase their hand temperatures by using temperature feedback training. The procedure was identical to that used by Sargent, Green and Walters, except that he did NOT use autogenic suggestions. The patient simply focused his attention on the feedback signal (gauge reading or tone) and concentrated on increasing his hand temperature. Both patients who had suffered from migraines for years, and had not responded well to other forms of treatments, found relief, and months after training, both patients reported that they had reduced their consumption of analgesics to occasional aspirin for non-headache related events. (p.434, Aldine, 1973).

The migraine sufferers have hand temperatures during their headaches of 70° to 80° or greater. Many patients find that as soon as they feel a migraine coming on, they can abort it by raising their hand temperature. However, if they are unable to block the oncoming headache within 15 minutes or so, the headache has most likely progressed to the point that some medication will be needed. Budzynski, 1973, states the goal of the treatment, "Eventually, migraine patients find they can exist without medication except in extreme circumstances or in cases of menstrual cycle headaches that occur once or twice each cycle."

The importance of home practice and stress-management outside the clinic cannot be over-emphasized. The patient must practice relaxation at least once every day. The rest of his family has to understand the importance of allowing the patient his 20 minutes to one hour period of isolation each day from the rest of the family.

Letters To The Editor

Dear Editor:

I was quite dismayed to read the recent article by Borton, et al, regarding the EMG biofeedback and the treatment of tinnitus, in the January 1979 issue of Corti's Organ. The comment that EMG biofeedback does not reduce anxiety and increase blood flow is correct. However, Borton, et al, left out any discussion regarding the method of temperature biofeedback. I hasten to point out that temperature biofeedback has been shown to reduce anxiety and increase blood flow because this method is a more direct link to the autonomic nervous system which in fact, controls blood flow (See Attached). EMG biofeedback does not provide that same connection.

I was further dismayed that this highly regarded publication printed an article suggesting that biofeedback as a treatment for tinnitus, be "discouraged" when the article was based on ONE patient. I refer you to Laryngoscope, March 1978, in which House reports on forty-one patients of which 80% (33) reported some degree of improvement. In direct contrast to Borton, et al, House encourages the use of biofeedback as a treatment modality.

I have referred over 20 patients with tinnitus to a biofeedback clinic and have found the House data to be supported. Much of the information presently being researched concerning the treatment of tinnitus with biofeedback is speculative, but evidence thus far does not suggest that its use be discouraged; in fact the evidence suggests that it should be strongly encouraged.

Sincerely,

Stephen D. Gannaway,
M.A. CCC-A

(Above paper on Biofeedback included).

Dear Editor:

In re De Rei Errata, the paper I gave at SENTAC, which you so kindly abstracted in Corti's Organ, appeared under the abstracts of AAS Papers. Can't you picture my friends scratching their heads and wondering, "where the hell was I when he gave that paper?"

Other than that, loved the issue!

Best regards,

Irving Shapiro, Ph.D.

Technical Problems Delayed the
October Issue of Corti's Organ.
This Issue is the Fall, 1979/
Winter, 1980 Issue.

CORTI'S ORGAN

The Official House Organ of the American Auditory Society

Vol. 4, No. 4/Vol. 5, No. 1

Winter, 1980

At dinner with the Board. Susan Conway-Fithian, Ross Roeser and Bruce Graham.

Ex-Pres. Blair Simmons with Pres. Elect for 1981 Ralph Nauntun.

AAS Members at dinner.

Executive Committee Members Malcolm Graham, Ralph Nauntun and Hiroshi Shimizu.

Gil Herer, Sue Kos, and Charlie Anderson at Executive Committee Meeting.

AAS at AAO is AOK

Good fellowship, good research papers, and the long awaited AAS presentation of its highest award, the Carhart Memorial, to AAS's first president Aram Glorig. These items were the bill of fare at the annual meeting of the AAS held in conjunction with the American Academy of Otolaryngology in Dallas, Texas on October 9. Blair Simmons as program chairman put together a stimulating program that included a number of distinguished scientists presenting some challenging scientific papers. But the most enthusiastically received was the lecture by Aram Glorig as the Carhart Memorial lectureship awardee for 1979.

Glorig presented a classic review entitled "Noise: Past, Present and Future" in which he described the origins of the noise problem, its recognition and the attempts man has made to solve the problem. No one else is as cognizant of all aspects of noise as Glorig, as he has devoted a lifetime to its study and attempts at solution. His interest began as long ago as 1943 when he dealt with noise exposure in the Army as an Army otolaryngologist. After the war he became Director of The Audiology and Speech Correction Center at Walter Reed Army Medical Center in Washington and continued his interest in noise induced hearing loss. Later he became chairman of the Subcommittee on Noise for the American Academy of Otolaryngology. There he published most of what is known about the problem of noise in industry, studies which are as valid today as they were then. From 1964 to 1977 he continued research into the problem as Director of the Callier Hearing and Speech Center and after leaving there went back to Los Angeles to pick up the threads of the work he had left there in 1964. There he is Associate Director of Research at the Ear Research Institute, is in charge of two major research projects, one on the aging ear and one on hearing aid design. In his office he examines patients who are involved in litigation for noise exposure and determines if the disability is related to the noise exposure. He serves as consultant in many litigation cases and on many committees concerned with noise in hearing. His excellent paper will be published in *Ear and Hearing*, so that members will be able to read it for themselves shortly.

Abstracts of the papers presented at the regular session of the AAS meeting are published in this issue. Readers can ascertain for themselves the high quality of the reports that were made.

Three new Board Members attending the meeting—Malcolm Graham, Susan Conway-Fithian, and Charlie Anderson.

Sam Lybarger and Ross Roeser at Executive Committee Meeting.

President Lybarger introduces Carhart Lecturer Glorig.

Bruce Graham telling his favorite joke at dinner.

Frank Brister.

Editor of the new AAS Journal *Ear & Hearing*, taking pictures, Ross Roeser.

Mike Kos

Editor of Corti's Organ—Marion Downs.

Newly elected Executive Committee Member—Susan Conway-Fithian.

Program Chairman Simmons flooring questions.

Questions being asked at the Scientific Meeting.

Award winner Aram Glorig listening with Howard House to AAS program.

Executive Committee Election winners announced

The following members were elected to the Executive Committee as a result of the election held last August:

Charlie D. Anderson	Ralph F. Nauntun
Susan Conway-Fithian	Hiroshi Shimizu
Malcolm C. Graham	John C. Sinclair
Ed W. Johnson	

These members will serve a four year term beginning January 1, 1980.

CORTI'S ORGAN is a quarterly publication of the American Auditory Society, printed in Dallas, Texas.

Editorial:

A Spade is a Spade

Well, we have to admit it - the docs really aren't that gung-ho about Audiology! Despite Blair Simmons' efforts to include the AAS meeting in the program of the Academy of Otolaryngology, the turnout was disappointing as compared with last year's attendance at the ASHA meeting. We'd better digest the fact that not many otolaryngologists care to learn more about audiology phenomena.

The good news of course is that the docs who do come to the AAS meeting are the elite of the Otolaryngology world: our own Blair Simmons, Aram Glogic, Ralph Naunton (the past and future presidents), Howard House, Malcolm Graham, Mike Paparella, Fred Linthicum, Hiroshi Shimizu, and several others. These men are a special breed of otologists who desire a more thorough understanding of the way auditory function relates to the anatomy, physiology and pathology of the ear. They are not satisfied with a grasp of mere routine clinical audiology. They are intellectually curious men who require a deeper knowledge of how the ear works in processing acoustic material.

Not that the acoustics and psycho-acoustics people attend any better when we meet with the Acoustical Society - the showing at the Miami ASA meeting was not that good either. But there are fewer of them and somehow we've been satisfied to have their best people with us too.

But facts have to be faced, and it looks as if two options are open to us. First, we can attempt a campaign to interest more otolaryngologists and acousticians in our society; and second, we can decide to cast our lot with the audiology group represented by ASHA, and hold meetings with them exclusively. If we do, the otolaryngologic elite and the acoustic elite will probably stay with us and be faithful in attending the meetings.

The Executive Committee would welcome hearing from the membership about this dilemma. Send your letters to Corti's Organ on this topic and we will publish them. MPD/RJR

Letter from England

Editors note:

PROFESSOR IMRE FRIEDMANN, our Foreign Correspondent for many years, was elected to the Fellowship of the Royal College of Surgeons, at a meeting of its Council on 12th April.

Every reader of Corti's Organ will want to congratulate him on this most recent of many honors, and to wish him well in his increasingly active 'retirement'.

Dear Editor:

I sent you a "Letter" and it ended just before the Wimbledon championships. You all have heard of the result and Jimmy Carter himself must have watched the Finals. The weather was glorious and the crowds huge in spite of the price of the traditional strawberries with cream: about two dollars for a small portion... Sport has dominated the last few weeks and has helped us to forget the energy crisis and all the other little and/ or threatening crises. We have so much to be thankful

for and to enjoy but party politics won't let us and we are dreading the Winter...

I attended the Gavin Livingstone Memorial Lecture in Oxford given by the well known audiologist from Manchester Professor Taylor on the Prevention of Sensorineural Deafness. A fascinating talk that has brought back memories of a great English gentleman. I saw Victor Goodhill for a moment but most of the audience had their thoughts already on the British Academic Conference in Birmingham. Let us hope that the rain although much needed will not spoil the social events.

I shall be very busy in the Fall starting in August and September working at various hospitals and trying to complete various publications. I hope I shall be on time with a chapter for a book to be published by a Denver pathologist.

Imre Friedmann

Letters to the Editor

Dear Editor:

An abstract of the paper we delivered at the 1978 American Auditory Society Convention appeared in the January 1979 issue of Corti's Organ. In the July issue, a Mr. Stephen D. Gannaway writes in to register his criticism over the content of the abstract, at the same time asking the editor to print an extended comment on treating migraine headaches with bloodflow feedback procedures. Mr. Gannaway has misinterpreted some of the information presented in the abstract and seems misinformed on several points. Consequently, we are taking this opportunity to respond to his communication.

Says Mr. Gannaway: "The comment that EMG biofeedback does not reduce anxiety and increase bloodflow is correct." Say we: That comment was not printed in the abstract, we presented no data upon which to base such a statement and, if Gannaway had the data, he didn't offer to share it. If he will re-read the abstract or, alternatively, have it read to him, he will find that we made a quite a different observation.

Says Mr. Gannaway: "However, Borton et. al. left out any discussion regarding the method of temperature biofeedback." Say we: We utilized electromyographic feedback throughout the course of the experiment and entitled the paper "Treating Tinnitus with Electromyographic Feedback." Stated differently, our paper did not deal with thermal feedback and any discussion of it would have been irrelevant to our purpose.

Says Mr. Gannaway: "...temperature biofeedback has been shown to reduce anxiety and increase bloodflow because this method is a more direct link to the autonomic nervous system which in fact, controls bloodflow (see attached), EMG biofeedback does not provide that same connection." Say we: Where is the support for that contention? The "attached" apparently refers to psychologist Keppner's monologue printed alongside the letters section. Unless our eyes deceive us and, alas, they do not appear to do so, Keppner makes no such assertion. What can Mr. Gannaway be talking about (More about Dr. Keppner in a minute)?

Says Gannaway: "I was further dismayed that this highly regarded publication printed an article suggesting that biofeedback as a treatment for tinnitus be 'discouraged' when the article was based on ONE patient." Say We: What Corti's Organ printed was not an article; it was an abstract and the difference should not have been unapparent. Even though the abstract mentioned a "double reversal" single subject experimental design, he apparently missed it. In fact, we utilized an "ABCABA" design, and Mr. Gannaway promptly fell into THE ONE SUBJECT TRAP.

Says Gannaway: "I have referred over 20 patients with tinnitus to a biofeedback clinic and have found the House (Dr. John House) data to be supported." Say we: Easy to say, difficult to prove. Where is the data? We hope Mr. Gannaway will provide some.

And herewith an observation of two of our own. (1) Mr. Gannaway has written a letter full of compounded anfractuities over the abstract of a paper, the data for which he has never laid eyes on. (2) We reached Dr. Donald Keppner, the Psychologist whom Gannaway credited with the accompanying piece on "Blood Flow Feedback Training." Dr. Keppner, in private practice in Atlanta and an enthusiastic and knowledgeable man, did not, however, know of Mr. Gannaway or the American Auditory Society or even Corti's Organ. After hearing what had been written, Dr. Keppner pronounced that although it was possible he could have written something on treating migraine patients, he did not remember writing what appeared in Corti's Organ. "As a matter of fact," he went on, "I did write some notes to go along with a lecture on this subject about five years ago, but I've never published them and they weren't about tinnitus." Mr. Gannaway appears to have taken considerable license in asking that such remarks be printed in support of his letter.

All in all, Mr. Gannaway's letter was a gross misinterpretation of our results and of the abstract which was published in

Corti's Organ. Had he addressed his concern to us instead of Corti's Organ, we would have been pleased to present him with our data and a more complete manuscript. We are always ready to grant our critic amnesty upon the showing of contrition and the promise to reform.

Cordially,
T. E. Borton
W.H. Moore, Jr.
S.R. Clark

Dear Editor:

As a proud new member of the American Auditory Society, I was particularly pleased to be invited by Mr. Pomerantz and Dr. Naunton to join its adjunct organization, the Greater Double Decibel Marching and Chowder Society.

I look upon this as a serious organization dedicated to establishing good will and fellowship among professionals in the related fields. As such, however, I believe that it should acquire all of the trappings of a true professional organization... such as a MOTTO and a SONG.

Though I did seek tacit approval of the following from Charlie Anderson, our leader here in Austin, I fear my query was ill-timed. His response was immediate, but not entirely intelligible. I hesitated to ask for clarification. (I did note that his remarks were primarily mono-syllabic, probably consisting of words with from 3 to 5 alphabetical characters.) The rest is referred to our friends in linguistics. (Lacking a more explicit answer, I feel I must interject at least a parenthetical disclaimer on his behalf.

Nonetheless, in the spirit of contribution to the cause, I propose the following:

MOTTO: "All Things in Modulation."

SONG: "Anthem to the Ear" (Sung to the tune of "All for Rice's Honor" - slightly modified)

Raise your glass and honor
The wondrous ear
Lavish praise upon her
Down your mug of beer.

All Things in Modulation,
And with frequency
Here's to the tube Eustacyan,
And to the Auditory Society.

(Cont. refrain)

Here's to Corti's Organ
May the hairs ever wave free.
Most wondrous of offices,
We love thee.

(Finish - with gusto!)

For we're the Greater Double Decibel
(Shout... I can't hear you well)
Marching and Chowder Society.

I do hope that these humble suggestions are accepted in the spirit in which they are offered, and that I will not seem forward in submitting same.

Yours very truly,
Wyndy Ellis

COCHLEOSCOPY:

A preliminary report of an ultimate Technique and Investigation

By: A. Axelsson and J. Miller

From the Institute for Cochleoexperimentalfiberoptics, and Microstructure, the Branch for Visualization of Hearing.

Introduction

Man's curiosity is as old as man himself. Curiosity relies upon the aid of the sensory organs of which vision has been of greatest benefit and significance (Glickstein, 1973, personal observation). The belief in what we see has always been greater than in what we hear, say, taste, smell, touch, etc. (e.g., I see, I see, as the blind man said; Plato). Medical curiosity has brought us the microscope and the endoscope, instruments with a seemingly ultimate refinement in our times. Few are the organs not being examined visually in the living patient. One of those, however, has been the snail, the cochlea, the organ of human hearing (Hawkins, et al., 1973, personal statements, Fig. 1).

Fig. 1
The aim of the present investigation has been to develop a new method for such examinations - cochleoscopy or in our mother tongue, snail peeping.

Literature Survey

Surprisingly, the first mention of cochleoscopy derives from the famous French Savarin(1) who used a simple method of examining snails with a device called Le Miroir D'escargot. Savarin, who suffered from severe shortsightedness, used his mirror to evaluate whether the snails he was going to serve his guests really contained the delicate and delicious sought-for specimen ("Seek and Ye Shall find," Hallen, 1973, personal communication). This, then, was the first indirect application of cochleoscopy in lower animal forms.

Later, Hippocrates (2), walking the beaches of Peleponnessos one day picked up one of the abundant snails and observed closely the vestibulum of the snail. His constant curiosity made him take a stone and crunch the snail in order to get a direct view of the inside.

Eureka!!! The first direct cochleoscopy was fait accompli (Fig. 2).

Fig. 2

FOOTNOTES

- (1)Savarin, Jean, 1945. L'examination de la nourriture avant de la manger. *Ann. Delicatesses.*, 1:2.
- (2) Hippocrates, Gary (Grandson(8) to the famous H), 1845; The diary of a Greek snail picker, J. Peleponessoss, 2:3.

The first documented cochleoscopies in the human were published years ago by Retzius (1837) who introduced a small straight tube in the cochlea of Swedish human cadavers. It is of some interest that Retzius' observations were directed on the lately much discussed "avascular channels" (Hawkins and Johnson, 1972, Fig. 3) which Retzius supposed constituted a particular sewage system for the cochlea. As is well known now, these channels are clearly documented to be post mortum artifactual collapsed vessels (Jordan, et al., 1973) a fact, which, Retzius, investigating the cadaver, obviously could not be expected to know. (3)

Fig. 3

It is to be noted that the approach first taken for development of cochleoscopy was based in part upon the experience gained by one of the authors (A.A.) during an intensive twelve-month postdoctoral study program in proctology. In this case, study and experience in a different orifice of the body provided the technical knowledge so necessary for the approach we have undertaken and found fruitful if not, indeed, satisfying.

Methods

Material:

A variety of subjects, human as well as animals, without racial regards or concern for sex, but with preference for sex, weight, sex, age, sex, height, sex, color, were used in the present investigation. As outlined below, certain defined groups proved particularly useful, i.e., aristocrats, bores, deaf, composers. However, most of the preliminary results are based on the findings in American volunteer medical students, other non-human primates, patients from Group Health, and American Indians (Fig. 4), since the availability and personal choice make these categories most easily achievable.

Fig. 4

Approach:

Briefly, our approach is based upon an attempt to introduce a flexible light source (fig. 5) and viewing tube into the labyrinth, in vivo, for the visualization of microstructure and function of the living cochlea. The primary characteristics of concern were: (1) size, (2) flexibility, (3) illumination, (4) visual definition and (5) an appropriate, astute and durable observer. As might be imagined, each of these characteristics presented a series of technical challenges on their own. However, the problems resulting from the interaction of each of these features (particularly # 5 with # 's 1-4) were of greatest difficulty and for future extension and development by young investigators (Liden, 1973) in this new, exciting field, must not be overlooked and cannot be underestimated. We have found it necessary to manufacture a set of cochleoscopy, each to be used for a particular clinical entity. (4) For development of our first cochleoscopy, we selected those most appropriate features of the gastroscope (fig. 6a), the fiberoptic system (Fig. 6b), and the Roto-Rooter (Fig. 6c). (5)

Fig. 5

FOOTNOTES

- (3)Admittedly, there was an earlier case published by Vergilius, (Rome, 53-63 AD) in a living female. However, it was later established that the case, in fact was a direct colposcopy which according to Vergilius' bad handwriting by the printer was misinterpreted as cochleoscopy.

Fig. 6 a,b,c

Recording:

The closed circuit television system, (as employed by Lawrence in similar investigations of the cochlea) was of major use. Alternatively, a small 35 micrometer camera (camera obscura) on a loan from the Department of Histology in Uppsala University, was on occasion introduced through the lumen of the cochleoscopy for snapshots of the fine structure. In addition, the size of the cochleoscopy permitted one additional observation, electrical potentials at the tip site of the instrument.

Attachments:

The following attachments for the cochleoscopy have been found useful for manipulation of structures and treatment of pathological conditions. Most of these attachments are of sub-light microscope dimensions. Development was no small task. (6) (1) vibratory probe, (Fig. 7) for gentle massage of tired stereocilia (suggested by G. McCandless); (2) cannula (Fig. 8) for injection of vitamins, hormones, silastic,

Fig. 7

Fig. 8

antibiotics, and more common medicines, (e.g., Heparin, Donaldson, 1973, personal preference) and for sampling of fluids. For repeated samples, however, we suggest using a disposable tip on the cochleoscopy (Hallen, 1973). (3) small rat-tooth forceps were found helpful for tissue sampling. (4) fine-toothed saw (Fig. 9) was used for trimming stereocilia (modified from Bohman's procedure).

Performance:

Fig. 9

The subjects can be assessed under local anesthesia (Fig. 10) or general anesthesia, the latter far to be recommended (Lamkin, 1973), somnolent information). Via an unconventional-Cont. on pg. 4

FOOTNOTES

- (4) These instruments are available commercially Millax Company Partners, Incorporated, Model No. 1-372, Patent Pending.

(5) This served to be a fortuitous decision, in that it worked. We must note that as in many fantastically beneficial discoveries, serendipity played a role. The ultimate solution to this difficult technical question came to the authors during one of our many evening working sessions. At the moment of careful application of the corkscrew to third bottle of wine (Chateau Troisième), the answer came simultaneously to both authors (perhaps slightly sooner to one, J.M.). Careful development of the idea was carried out on six additional subjects (Chateau quatrième-neuvième). The addition of a Roto-Rooter control device came unexpectedly the following morning.

- (6) Our special appreciation to the many small helpful comments made by Dr. H. Angstrom at the recent NASA meetings held in Guadalupor, Micronesia, June, 1973.

(Cont. from Page 3)

tional tympanotomy (Holmquist), the cochleoscope will be introduced through a, hopefully, small slit in the round window membrane (Axelsson) or a hole in the stapes footplate (Miller) or, lately, through the external wall (Hallen, Seattle,

Fig. 10. Locally anesthetized patient assisting the cochleoscopist by indicating where the instrument should be introduced.

September, 1973) into the scala media or, admittedly more difficult, through the endolymphatic sac and duct (Axelsson & Miller). Cochleoscopy can easily be performed as an office procedure (Fig. 11).

Fig. 11. Patient (medical student) demonstrating the ideal position for right sided cochleoscopy.

The scope is gently pushed through the respective scala under close visual observation of intracochlear structures, the observer, and the audioscilloscope. Particular care must be taken in passage of Corti's duct, which due to the energy crisis is often poorly enlightened. The withdrawal of the instrument is achieved by completely opposite movement to the introductory. The introduction site must be sealed by a piece of chewing gum, well chewed, (Wrigley's et al., 1973, Fig. 12).

Technical Experiences Fig. 12

In addition to the visualization of the intracochlear structures, well known to all our readers, it has also been possible to add a device for registration of sound originating in the Organ of Corti. Any kind of sound, spoken or music, can be transmitted to the outside world. Surprisingly, this is not only the case with sound from the surroundings but also melodies or sentences that originate in the patient's mind (probably mediated via the aberrant bundle, Wersall, 1973). In this way, we are able to closely follow the patient's reaction of the procedure, critical or praising comments, and adjust the performance in accordance to them. The future of this "sonoprinting" cannot be overemphasized. Several composers have already expressed an interest in the advantage of the objective registration of their musical fantasies. However, a problem remains in excluding verbal garbage (G. Strothers) or indecent comments which all too frequently mixes into the musical associations.

Precautions

Electrophysiological

As is well known, the endocochlear potential originates in the stria vascularis (McPherson, 1973, personal observation). Our findings have made it possible to visualize the "battery" in the stria vascularis (Fig. 13). The first close-up examination of the potential, however, was quite uncomfortable to the investigator. The result of our curiosity and close

Fig. 13

observation of the origin of the DC potential was a severe electric shock. Later models of the cochleoscope are additionally equipped with a lightning rod grounded in the perilymph (suggested by B. Simmons).

Mechanical Trauma

It is to be noted that this procedure cannot be immediately put to use in humans by the naive operator. We suggest many hours of pre-op training on cadavers and animals (e.g. snails) prior to use in humans. This, of course, will vary with the motor competence and handball/ cigar/ coffee addiction of the surgeon (Donaldson, 1965-73). Our first attempt to introduce this device for exploration of the scala media was not without mishap. Just as the cochleoscope rounded the "hook region", the patient (Xavieria Hollander) suffered a severe gastro-intestinal disturbance (peripheral efferent in nature). This produced an inadvertent movement of the cochleoscope resulting in slight damage (arrows) to Corti's Organ in a restricted area of the basal turn (Fig. 14). (This patient has since been transferred to Los Angeles. However, unfortunately, a cochlear implant did not help. This result is noteworthy, however, since it may be the one case in cochlear implant did not produce satisfactory results that will be available in print.) Caution is suggested at all times in the use of this instrument. Untoward effects have been demonstrated to result in cochleoscopy which in turn may result in single cell isolation (Flock, 1973). Accidents, as these, should not discourage the naive investigator; they never discouraged the sophisticated one. Indeed, we feel our approach to the scala media is effective.

Fig. 14

Physiological Findings

Using the uninsulated tip of the cochleoscope, it was possible to determine the origin of the intracellular resting DC potential. This was only found in cases of severe sensorineural hearing loss, where the membrane literally "rested" on the hair cells. The potential measured at 23 V (Fig. 15) was recorded from the internal parts of the degenerated cells (DC).

Fig. 15

Lately, critical foreign voices have been raised concerning the injection of contrast media in the intracochlear vessels ("rubber", Johnsson, 1973, Dallas). However, our experiences in aristocrat patients have demonstrated that these patients have naturally occurring Prussian blue of the same color and intensity as those animals injected with the contrast (Compare Figs. 16a and 16b).

Fig. 16a Vessels from aristocrat containing "blue blood", 16b Vessel from monkey injected with Prussian blue (reprint kindly permitted by L.G. Johnsson)

This indicated that more aristocrats in the future should be examined both in vivo and in vitro, particularly if exhibiting hearing disorders. Additionally, in vitro examination of the cochlea of the bore, captured in the Schwarzwald in Germany, shows naturally occurring Prussian blue in the vessels of the left cochlea (Fig. 17). Clearly is is somewhat premature to generalize this isolated finding to humans. However, we do feel that this finding clearly supports and justifies further use

of Prussian blue injection for the study of the cochlear vasculature. Equally, we are open minded in the use of osmic acid if this stuff can be demonstrated intracochlearly in our future studies of any living animal (same goes for Araldite).

Pathology Fig. 17

Our extensive experiences in the maladies of the snail must here be space-limited to two conditions: Noise-induced hearing loss and prosperity disease.

1. Noise-induced hearing loss

The cochleoscopy clearly demonstrates the changes induced by noise (Fig. 18). In early stages (temporary threshold shift), first the extreme and then the whole basal turn was elevated and shifted upwards towards the second turn (as predicted by Snyder, 1973). Long-standing observations which required much patience from the patient and the voyeur clearly showed that the shift (elevation) Fig. 19

Fig. 18

was temporary and the basal turn always reassumed its original position. Contrarily, in early stages of permanent hearing loss, the erection of the stereocilia is lost, they appear "tired, slacking, bent down, shrink, and then disappear (Fig. 19). The proud elevation of their heavy cover, the tectorial membrane (Lawrence) is lost and the cover rests directly on the cell bodies. Interesting and promising treatment measures permitted by the cochleoscope have made this degeneration reversible, also in pronounced cases. Different measures include:

oxygen supply directed to the outer hair cells (Fig. 20)

microinjection of vitamins in the cells Fig. 20

delicate caressing of the cell bottom by the aid of brushes (Fig. 21)

injection of hormones in the outer hair cells Fig. 21

administration of silence

the injection of silastic in the tectorial

membrane

the massage with a vibrator (Lim's Shaker Fig. 22)

Fig. 22

2. Meniere's disease

Surprisingly, this condition was clearly established to be caused by two different etiologies: 1. We found it to be a dental entity being caused by decay of the Huschkes' dents. The cooperation of the microdentist has resulted in promising improvement of this condition by prophylactic means, i.e., fluor treatment (Shambaugh) and by the otodontic treatment of established disease by the use of tooth wheels. 2. We have been able to verify the pathological correlate of the disease named by the French Prosper Meniere which we, according to the promising treatment, would like to rename to Prosperity Disease. (Admittedly, one of the authors, J.M., wanted it to be renamed after him, i.e., Miller's Disease, which however was not accepted by the cowriter, who would rather use this descriptive name for flour allergy, formerly so

(Cont. on page 5)

(Cont. from pg 4)

common of Miller's noses.) The correlate to the disease has been visually verified to be the so-called Johnson's pink-pants (Fig. 23), a pathological formation of empty vessels similar to the well known Finnish long-drawers, located in the small

Fig. 23

bag, sacculus, and constantly pouring out large amounts of fluid without matter. The appropriate treatment for the disease is a general one, surprisingly also of Finnish origin, i.e., dehydration in dry sauna. The direct method for treatment is the so-called snail straw (cochleosuction), easily applied through the scope (a pre-op diet including Kim Chee is to be avoided. Lim.

Fig. 24

Likewise, surprisingly, the sound created by the suction tip (Hallen's device) is very similar to the sound created by the oral removal of the delicious fluid in the far-away hiding places of the French escargot.

Conclusion

Time and space have limited us to regrettably short aspects of snail peeping or cochleoscopy. Immense, if not eternal, are the projections of this new method for the restoration of cochlear anatomy and function and diagnosis and therapy, such as the use of this procedure, device and approach to assist in the transplant of the living cochlea (Vernon, 1973, after Dallas, high flying suggestion). In future reports we hope to present to our readers, the almost unlimited experiences we now possess.

Multi-disciplinary Workshop on Rehabilitation through Amplification

The American Hearing Research Foundation is conducting a Multi-Disciplinary Workshop on Rehabilitation Through Amplification, June 20-25, 1980, at the Pick-Congress Hotel in Chicago, Illinois. The Workshop will be of interest to otolaryngologists, audiologists, hearing aid manufacturers and hearing aid dealers. Sessions on earmolds, tinnitus and masking, medical aspects of hearing impairments, testing of the hearing aid, acoustic testing, special considerations of amplification for infants and children, new federal legislation impact on hearing aid, acoustic testing, special considerations of amplification for infants and children, new federal legislation impact on

hearing aid dispensing, and lectures on the planning and organization of your business operation, are the informative areas that will be covered in this workshop. This continuing medical education offering meets the criteria for 34 hours of credit in Category I for the Physician's Recognition Award of the American Medical Association. For further information contact:

Behind the Iron Curtain with AAS

AAS's European counterpart, the International Audiology Society, will hold its XV Congress in Krakow in September 1980. To make it reasonable and congenial for AAS members to attend, group tours are being planned for members, their families and friends.

Among the AAS members who will present papers in Krakow will be Ralph Naunton, Aram Glorig, LaVonne Bergstrom and Marion Downs. Phillip Peltzman will also be on the program. There will be three plenary sessions:

(1) Evaluation of Auditory Function after Surgical Procedures, (2) Etiologic Factors in Sensorineural Hearing Loss, and (3) Paedaudiology. In addition, contributed papers will be presented.

Two options are being planned for the tour: one a seven-day trip to the Krakow Congress and back; the other an additional week's tour of Vienna, Budapest and Southern Russia.

TOUR 1

Sunday, August 31 leave New York
Monday, September 1 arrive Krakow
September 2-6 attend Audiology Congress
September 6 leave Krakow for Warsaw
September 7 tour Warsaw
September 8 return to New York

TOUR 2

Sunday, August 31 leave New York
Monday, September 1 arrive Krakow
September 2-6 attend Audiology Congress
September 6 leave Krakow for Vienna
September 7-8 tour Vienna
September 8 fly to Budapest
September 9-10 tour Budapest
September 10 fly to Kiev, Russia
September 11-13 tour Kiev
Sunday, September 14 leave Kiev for New York

TOUR 1

*Air Fare to Krakow and return from:

Dallas	
Denver	
Los Angeles	
Other Western Cities	\$895.00

Chicago	
St. Louis	
Detroit	
Other Mid-Western Cities	\$845.00

New York	\$695.00
----------	----------

TOUR 2:

Air Fare plus ground travel, hotel accommodations (with breakfast), for extra week in Vienna, Budapest & South Russia:

Add \$640.00 to above prices.

NOTE: These prices include special baggage handling, assistance at departure & hotels, and a cocktail party prior to departure at J.F.K. Airport.

*All fares are approximate & subject to changes such as fuel surcharges.

Raves on Vanderbilt Conference

One of the finest meetings in many years was held in Memphis in September, titled an **International Symposium on Amplification in Education**. Sparked by Fred Bess of Vanderbilt, it tackled some of the novel problems that professionals are faced with in carrying out the mandates of the 1975 Education for Handicapped Children Law.

The speakers pointed out the mind-boggling impact of the Law on the responsibility of speech, hearing and language clinicians as well as deaf educators. More and more these professionals will serve as adjuncts to the primary classroom teacher. It will be incumbent on them to manage effective amplification in the classroom whether with individual hearing aids, FM systems or other auditory trainers. A number of speakers addressed themselves to these problems, among them: Harry Levitt, Ph.D.; Norman Erber, Ph.D.; Dennis B. Fry, Ph.D.; Daniel Ling, Ph.D.; Julia Davis, Ph.D.; Arthur Boothroyd, Ph.D.; Mark Ross, Ph.D.; Wayne Olsen, Ph.D.; F.A. Niemoller, Ph.D.; Vernon D. Larson, Ph.D.; Noel D. Matkin, Ph.D.; Barry A. Freeman, Ph.D.; Steve Sinclair, M.A.; Derek Sanders, Ph.D.; Gloria Hoversten, M.A.; Daniel M. Schwartz, Ph.D.; Steffi B. Resnick, Ph.D.; Dennis Byrne, Ph.D.; Andreas Markides, Ph.D.; Larry E. Humes, Ph.D.; Fred H. Bess, Ph.D.; Don Riggs,

A.E. and Marion Downs, M.A.

Dr. Eric Wedenberg of Karolinska Institute in Sweden was the honor guest speaker, reviewing the history of the development of auditory training. Marion Downs gave the banquet address, "The 11th Commandment: Thou Shalt Listen".

Fred Bess, Barry Freeman and Steve Sinclair comprised the committee's responsible for this outstanding symposium. The transactions will be published. Watch for them.

WORKSHOPS IN ELECTRONYSTAGMOGRAPHY

Conducted by
Darrel L. Teter, Ph.D., of Denver, Colorado,
With Outstanding Guest Otolaryngologists

A practical discussion of clinical techniques, applications and interpretation of the ENG test battery, with "hands-on" practicum.

St. Louis, Missouri

November 3 & 4, 1979
With Donald B. Kameron, M.D.

Birmingham, Alabama

February 22 & 23, 1980
With Dennis G. Pappas, M.D.

and during 1980, workshops in

Chicago, Illinois

San Francisco, California

Washington, D.C.

Austin, Texas

CONTEMPORARY AUDIOLOGY WORKSHOPS

Jerry L. Northern, Ph.D. Darrel L. Teter, Ph.D.

A comprehensive 1½ day review of contemporary clinical audiology, including ...

- The current audiometric test battery
- Impedance
- B.S.E.R.
- Electronystagmography
- Microprocessor techniques in audiology
- Testing hearing in children
- High frequency audiometry
- Improved Sound Field testing
- New procedures in hearing aid fittings

ADVANCE REGISTRATION \$35

First workshop in the series ...

DECEMBER 6 & 7, 1979

Ramada-Gondolier

Word Discrimination in Quiet and in Noise A Re-Examination

Gail D. Chermak
Joan Dengerink

Department of Speech
Communication Disorders Program
Washington State University
Pullman, Washington 99164

The purpose of the present investigation was to establish developmental norms for word discrimination in quiet and in noise in a normally hearing pediatric population. A second purpose of the study was to investigate the influence of minor variations in noise level for word discrimination performance.

Twelve children from each of four age groups (X age \times 7, 9, 11, and 13 years) and 12 college students participated in Experiment I. Hearing sensitivity and tympanometric measures were within normal limits bilaterally for each subject. Each pediatric subject presented scores within one year of grade level on the language subtests of the *Iowa Tests of Basic Skills*. A Spondee Threshold (ST) was obtained for each ear for each subject.

An Auditec tape recording of *Northwestern University Auditory Test No. 6* (NU-6) served as test stimuli. Both NU-6 lists and white noise were presented via a GS 1701 audiometer fed into one TDH-49 earphone. Right or left ear of each subject was selected for experimental listening on an alternate basis. Each subject participated in two experimental conditions & word discrimination in quiet at 40 dBSL (re: ST), and word discrimination in white noise ($S/N \times 0$ dBHL)*. Order of experimental condition was randomly determined for each subject.

Eleven normally hearing college age adults and 7 of the original nine year olds (now ten years old) and 5 of the original eleven year olds (now twelve years old) participated in Experiment 2. Experiment 2 was identical to Experiment One except for the addition of a third experimental condition. The three experimental conditions of Experiment 2 were: 1) NU-6 discrimination in quiet (at 40 dBSL re: ST), 2) NU-6 discrimination in white noise ($S/N \times +2$ dB). In the latter condition the signal remained at 40 dBSL re: ST while the white noise was attenuated 2dBHL.

Word discrimination scores in percent correct were calculated for each subject for each experimental condition. The data was analyzed using factorial analyses of variances with repeated measures on one factor. Analysis of the data from Experiments 1 and 2 revealed significant condition effects beyond the .01 level of confidence. No significant age or age by condition effects were found in either set of data. Duncan's Multiple Range Test revealed that performance in quiet and in both noise conditions ($S/N \times 0$ and $S/N \times +2$) were all significantly different at the .05 level of confidence.

The data generated in the present experiments revealed the marked variability in word discrimination in noise performance of normally hearing subjects found by other investigators (Olsen et al., 1975; Cooper and Cutts, 1971; Keith and Talis, 1970). As noise level increased (S/N ratio decreased) variability increased word discrimination in noise did not vary consistently as a function of maturation; therefore, the present version of this test is too difficult to reveal developmental differences in speech discrimination in noise. One might have expected a significant age effect due to increased listening skills, experience, language facility, and attention capabilities of older children and adults compared to younger children (Chermak and Zielonko, 1977; Maccoby, 1967; Kalikow et al., 1977).

The data obtained with the adult subjects do not agree with the data of a similarly designed study (Olsen et al., 1975). Speech in white noise difference scores & word discrimination score in quiet minus word discrimination score in noise ($S/N \times 0$)* from Experiment 1 ranged between 52-70 percent for 50 percent of the adults. Olsen et al. (1975) found difference scores ranging between 20-28 percent for 60.6 percent of their normally hearing adult subjects. As Kruei et al. (1968) observed, differences in speech discrimination scores between clinics emphasize the need to control not only test materials but also equipment, environment, noise and talkers. As suggested by the results of Experiment 2 (and suggested by Coles et al., 1973) control cannot substitute for the collection of normative data, for a 2dBHL variation in noise level, which is acceptable under ANSI S3.6 (1969) calibration tolerances for speech audiometers, can result in significant differences between word discrimination scores. Therefore, differences in speech in noise scores between clinics may be due to calibration tolerances. Other variables contributing to the discrepancy in word discrimination in noise findings between clinics are: 1) the use of Auditec versus Northwestern recordings of the NU-6 lists (Wilson et al., 1976, found the Auditec intelligibility function to be displaced by 5.2dB to the higher sensation levels relative to the Northwestern recording); 2) the use of the TDH-49 earphones versus TDH-39 earphones, the former present a flatter high frequency response; and 3) different definitions of Ob S/N (OdBSPL or OdBEM).

BINAURAL INTERACTION IN HUMAN AUDITORY EVOKED RESPONSES

R.A. Dobie,
S.J. Norton

Veterans Administration Medical Center
and
Department of Otolaryngology
University of Washington
Seattle, Washington

Binaural interaction (BI) is a prominent feature of brainstem auditory function, as shown by single unit recordings, behavioral studies after experimental brainstem lesions in animals, and clinical studies. Since brainstem evoked responses (BSER) reflect activity in the brainstem auditory nuclei, it is appropriate to study BI in BSER.

Dobie and Berlin (1979) demonstrated BI in the BSER of guinea pigs. It was assumed that in the absence of BI, responses attributable to activity in the right and left "channels" would add according to the principle of superposition in linear systems. Thus, response to binaural stimuli would be equal to the algebraic sum of the responses obtained when the two monaural stimuli were given separately: $B(t) = R(t) + L(t)$. Any non-linearity could be detected by subtracting the sum of the monaural responses from the actual binaural response, and must be attributable to BI.

BI in guinea pig BSER is striking, reproducible, and persists for a surprising range of stimulus parameters: intensity to near threshold, t up to 3 msec., and I up to 40 dB.

This paradigm has not previously been applied to human BSER or middle-latency auditory evoked responses (middle AER). We studied both, because our pilot studies suggested a large inter- and intra-subject variability in BI in BSER.

Sixteen young subjects had BSER and middle AER recorded, using conventional stimulus and signal processing procedures, for monaural and binaural clicks at two intensity levels (approximately 65 and 35 dB - SL). Amplitudes and latencies of all peaks were measured; each binaural trace was compared to the appropriate "sum-of-monaurals" or "P" trace, since it represents the linear model's prediction of binaural response. Difference ("D") traces were generated by subtracting the P from the B traces.

Most subjects showed BI in BSER. The morphology of the response was similar to that seen in guinea pig BSER, although with increased latency (6 vs 4 msec.). However, there was considerable individual variation: some normal subjects showed no replicable BI. The latencies of response peaks in the "D" trace (representing BI) were always intermediate between peak latencies in the raw BSER. There were no significant differences in the group mean amplitudes and latencies of the B and P traces.

In contrast, a large BI effect was seen in 12/16 subjects' middle AER (the other four had been excluded from analysis because of very large, and presumably myogenic, potentials in the middle AER time frame). At both the high and low stimulus intensities, the amplitude of peak "Pa" was much smaller for binaural stimulation than for the sum of monaural responses.

As a first approximation, binaural BSER in man is

well-predicted by summing monaural responses. BI is present, but is subtle and highly variable. Differences between human and guinea pig recordings may be explained by innate experiments, stimulus parameter differences, etc. BI was more prominent in middle AER. However, myogenic responses complicate interpretation of these results.

MONDINI'S DEAFNESS A review of Histopathology

Michael M. Paparella
Department of Otolaryngology
University of Minnesota
Minneapolis, Minnesota

Introduction

Next to Scheibe's deafness, Mondini's deafness is probably the most common form of congenital genetic deafness. Mondini's deafness has in recent years been more frequently diagnosed largely because of polytomographic studies which are available in most clinics, especially since 1969, when Valvasori described the application of polytomographic radiography. Since that time, diagnostic studies using polytomographic methods have been described by Illum 2 (1972), Jensen 3 (1974), Everberg and Jensen 4 (1976), Som et al 5 (1977), Subotic and Schuster 6 (1978), Valvasorri and Clemis 7 (1978), and Ibrahim and Linthicum 8 (1979). Even such quantitative radiological studies can be misleading. For example labyrinthitis ossificans can not be differentiated from osseous labyrinthine aplastic changes radiologically. There is a great need for histopathological studies of human material to substantiate such diagnoses in patients and in turn appropriate management should result.

The mechanisms for sensorineural hearing loss in Mondini's deformity has not been well established, perhaps because there are so few histopathological studies in the literature. These studies generally concentrate on Mondini's deformities rather than pathogenesis of Mondini's osseous anomaly is not necessarily associated with hearing loss. Polvogt and Crowe 9 in 1937, described cases with normal hearing in which Mondini's bony cochlear anomalies existed. Vestibular labyrinthine anomalies are less frequently described although, as this study will show, such changes can occur. The literature on this subject is characterized by individual case reports. Following Mondini's original description of gross findings in 1791, Alexander (10) was first to describe the microscopic features. In 1950, Altmann (11) cited earlier described cases of Mondini's deafness. He also stated that the "extent of the changes of the stria vascularis, organ of Corti, spiral ganglion cells and the other parts of the cochlear system determined the degree of hearing loss, and that clinically malformation of the Mondini's deafness. He also stated that the "extent of the changes of the stria vascularis, organ of Corti, spiral ganglion cells and the other parts of the cochlear system determined the degree of hearing loss, and that clinically malformation of the Mondini-type might therefore, show complete deafness or only partial loss of hearing." Since then cases have been described by Murakami and Schuknecht 12, Gussen 13, Paparella and Elifky 14 and Lindsay 15.

This report contains a general survey of 12 human temporal bones (9 plus the 3 originally described) of Mondini's anomalies and deafness with a discussion of pathogenesis of hearing loss and vestibular findings.

DISCUSSION

Of the 12 cases assessed the following interpretation of summarized aggregate findings include: absent vestibular labyrinth (semicircular canals and vestibule) with absent associated neural elements (5 cases); $1\frac{1}{2}$ or fewer cochlear turns (11 cases); large endolymphatic duct and sac (6 cases); organ of corti lesions sufficient to explain sensorineural hearing loss (7 cases); middle ear changes sufficient to cause conductive or "sensorineural" hearing losses (8 cases).

It was surprising to see total aplasia of the vestibular labyrinth (pars superior) and nerves in so many cases (5 out of 12). It is well known that the pars superior (semicircular canals and utricle) are phylogenetically older than the pars inferior (sacculle and cochlear duct). These findings are at variance with the time tested rule that embryology mirrors phylogeny or that the older a structure is phylo-genetically the more resistant it is to developmental defects. What we commonly find are cochlear congenital lesions with preservation of vestibular function. Moreover, these unusual cases of aplasia of the vestibular labyrinth provide a unique opportunity for vestibular physiologists to study equilibrium problems or lack thereof in such patients. Enlarged semicircular canals were seen in other patients, another

Minutes of the Executive Committee of the American Auditory Society

Applicants for

Membership

1979

DATE: October 7, 1979
PLACE: Dallas, Texas
TIME: 4:30 P.M.
MEMBERS PRESENT:
Charlie D. Anderson (Non Voting)
Susan Conway-Fithian (Non Voting)
Marion P. Downs (Non Voting)
Bruce Graham
Gilbert Herer
Susanne Kos
Sam Lybarger
Ralph Naunton (Non Voting)
Ross Roeser
Hiroshi Shimizu
Blair Simmons

MEMBERS ABSENT:
James T. Benitez
David Dolowitz
Earl Harford
Norma Hopkinson
Merle Lawrence
Fred Linthicum
W. Dixon Ward
Laura Ann Wilber
J. Donald Harris

- President Lybarger opened the meeting at 4:30 p.m.
- The minutes from the 1978 Executive Committee Meeting, held in San Francisco, California, were presented and approved without change.
- The income and disbursement statement from the period January 1 through August 31, 1979 was presented, discussed, and approved.
- A list of 91 persons who had submitted applications for membership during 1979 was presented. The list included applicants' names, highest degree held, city and state of residence, and the names of the members sponsoring the applicant. The applicants were approved for membership, with the exception of one whose application was incomplete. Upon obtaining the sponsorship of one more member, the applicant who was not approved will be admitted to membership. The names of those accepted as members will be published in the next issue of Corti's Organ.
- The meeting site for the 1980 annual meeting of the Society was changed from Los Angeles (it was to be held in conjunction with the winter meeting of the Acoustical Society of America) to Detroit, preceeding the annual meeting of the American Speech and Hearing Association. It was felt that because the largest portion of our membersip does attend the ASHA conference, consideration be given to having the annual meeting alternate between ASHA and another group.
- Bruce Graham was appointed as the Program Chairman for the 1980 Annual Meeting. He will solicit help from two additional members of the Society, one an otolaryngologist, and the other a representative from the hearing aid industry.
- A discussion was held regarding the possibility of the Society sponsoring a national meeting. Bruce Graham and Norma Hopkinson were appointed co-chairment of a committee to explore the possibility of such a meeting. The possibility of having a meeting in conjunction with the Academy for Research in Otolaryngology in St. Petersburg, Florida in 1981 will be explored. the Committee will report to the Executive Committee at a future date on this possibility.
- After discussing the Carhart Memorial Lectureship, a motion was made that a committee be formed consisting of the President, immediate Past-President, and President-Elect to develop a list of three possible candidates and present the list for vote by the Executive Committee prior to December 31, 1979.
- Ross J. Roeser was appointed Secretary/Treasurer for 1980 and 1981.
- Suzanne Kos was appointed Assistant Secretary/Treasurer for 1980 and 1981.
- Ralph Naunton was appointed Vice-President/President-Elect for 1980-81.
- President Lybarger discussed the implementaton of a membership drive. At present the Society has only minimal recruitment activities. In order to keep the membership dues at a minimum and support the journal the membership should grow substantially in the next 2-3 years. Several alternatives were discussed and following this discussion a committee was

appointed consisting of Charlie Anderson, Susan Conway-Fithian, Malcolm Graham, and Hiroshi Shimizu (Chairman).

13. The Executive Committee voted unanimously that a letter of commendation be prepared and sent to Dr. J. Donald Harris for his outstanding efforts in developing the Journal of the American Auditory Society.

14. Discussion was held regarding the new journal, Ear and Hearing. Ross Roeser has been appointed Editor-In-Chief. He stated that the entire format of the journal will change and reviewed the specific changes that will occur.

The new journal will be designed principally for the practicing clinician/physician/educator who is dealing with the assessment, diagnosis and management of auditory disorders. The journal will take on a "clinical" theme, and will be in direct harmony with the aims of the American Auditory Society.

Featured in the new publication will be submitted manuscripts on clinically-relevant topics, as well as regular sections that will be edited by the folowing persons: Phillip A. Bellefleur (Secion on Auditory Education and Rehabilitation), Henry M. Carder (Resident and Audiology Fellow Section), J. Donald Harris (Original Articles Section), Robert W. Keith (Clinical Notes Section), Todd Porter and Eugene C. Sheeley (Book Review), F. Blair Simmons (New Developments in Otology Section), John C. Sinclair (Techniques and Applications of Hearing Aids), and W. Dixon Ward (Foreign Translations Section). Invited papers will also be requested from well known authorities on specific topics and will appear in the Original Articles Section. The invited paper will be sent to selected reviewers for their comments, and the comments on the manuscript will be published along with the manuscript. A rebuttal regarding the comments will also appear if the authors of the manuscript wish to submit one.

15. Marion Downs gave a report on Corti's Organ. The Executive Committee commended her for the publication and had no suggestions for revision or addition.

16. It was suggested that the Executive Committee give consideration to opening another class of membership in the Society. Specifically, an Associate Membership category was discussed. The Associate Member would not be required to have a Bachelor's degree, and would not have voting privileges. It was also suggested that the signature requirements be waived for Associate Members.

It was recommended that a committee for changing the Bylaws be formed to study the Associate Membership category and a motion be prepared for a revision that will be circulated to the Executive Committee for vote. Dix Ward was appointed chairman of the committee.

17. There being no other business, the Executive Committee adjourned at 7:48 p.m.

subject for further observation and study.

Characteristically, Mondini's patients demonstrate a shorter cochlear duct that is $1\frac{1}{2}$ instead of $2\frac{1}{2}$ turns. 10 out of 12 cases showed such a shortened cochlear duct. 2 out of 12 contained a missing bony interscalar septum which could have been misdiagnosed as Mondini's deafness by polytomography whereas Schiebe's deafness was found to explain the hearing loss. Two of these cases (11 and 12) contained no cochlear turns but an even more rudimentary single common cochlear space. Surely this genetic lesion was more profoundly initiated earlier in the first trimester.

In this series, end organ cochlear lesions and associated neuronal deficiencies interpreted as being sufficient to account for a serious sensorineural hearing loss were seen in 7 cases. However, 2 of these (9 and 10) were Schiebe's deafness with which a full compliment of cochlear turns was seen histologically. Thus 5 cases out of 10 with a shortened cochlear duct contained end organ lesions or there were 5 cases where the cochlear labyrinth otherwise appeared normal. In these later cases, many speculations or interesting questions can be raised relative to inner ear hydrodynamics, traveling wave phenomenon, frequency range, pitch perception, etc. If other temporal bone anatomical and physiological conditions were normal, would these cochleae function normally? Abnormally? Why and how? Unfortunately, as this study demonstrates, middle ear pathological factors can complicate inner ear transmission and function. Otherwise, these cases provide an interesting model for auditory physiologists to study. One further thought is that these patients properly selected and screened may become excellent cochlear implant candidates in the future.

In these patients in whom organ of Corti lesions were found the characteristic finding was aplasia of part or all of the organ of Corti more apparent towards the basal turns. Lesions in the upper turns were also seen. These lesions were usually accompanied by absence of neural elements (ganglion cells and nerves). The stria vascularis and spiral ligament generally appeared normal as did the position of Reissner's membrane.

In Mondini's deafness middle ear pathology can affect inner ear function and may appear as profound sensorineural hearing loss audiologically. A Mondini deformity may be associated with absence of the oval and round window along with other aplastic lesions of the middle ear (e.g. cases 1,2,6&7). Such loss of preferential sound conduction to and phase differential at the windows could be expected to result in a sensorineural hearing loss although, the sensory structures of the cochlea appear normal.

As this study and other studies have shown a large endolymphatic duct and sac are often seen in Mondini's cases. As we see in this series this can be true even in the absence of a vestibular labyrinth whereas the opposite might be expected. The utricle-endolymphatic valve is usually deficient or missing and there often exists a direct and large communication between the endolymphatic sac and the scala media. Endolymphatic hydrops or Reissner's collapse were not seen in this study and the stria vascularis generally appeared intact. So in spite of these, in some instances grossly abnormal findings, conditions appear suitable for an operational longitudinal flow theory as regards endolymph.

METABOLIC MAPPING OF COTICAL AUDITORY ACTIVITY IN MAN: A PRELIMINARY REPORT

William F. Rintelmann
Joel Greenberg
Abass Alavi
Martin Reivich
James B. Snow
David Christman
Joanna Fowler
Alfred P. Wolf

From the Cerebrovascular Research Center, and University of Pennsylvania School of Medicine, Philadelphia, PA;

Using the recently developed 18 F-fluorodeoxyglucose technique for the measurement of local cerebral glucose metabolism (Reivich et al., *Circulation Res.*, 1979) in conjunction with a positron emission tomographic scanner (PETT III), it has been possible to determine which areas of the brain are activated by a specific sensory stimulus thus enabling neural pathways to be mapped in vivo in man. Following a bolus injection the fluorodeoxyglucose in the plasma is transported into the brain tissue in a manner similar to that of glucose. Once in the tissue, it is phosphorylated to (18 F)-2-fluoro-deoxyglucose-6-phosphate which is essentially trapped in the tissue over the time course of the measurement. The tissue activity of FDG-6-P was measured using the PETT III tomographic scanner and the arterial time course of FDG was determined. With these data and knowledge of certain constants it is possible to calculate local cerebral glucose metabolism for any region of the brain with a resolution of 1.7cm (Reivich et al., *Circulation Res.*, 1979).

The auditory system was studied in young right handed male adults with normal hearing. The subject listened to tape recorded connected discourse consisting of a factual story read by a male talker. To reduce ambient noise in the test

environment both ears of the subject were covered by TDH 39 earphones housed in Maico Audiocup enclosures; however, the auditory stimulus was presented only to one ear at 75 dB sound pressure level (re 20 μ N/m²). Attentiveness to the story was assessed by testing the subject's recall at the end of the story. The subjects were blindfolded to avoid contamination of the findings by visual stimuli.

The auditory stimulus was initiated approximately two minutes prior to the administration of 5-10mCi (18F)-2-fluoro-deoxyglucose as an intravenous bolus injection. The stimulus was continued for 60 minutes following the injection. Arterial plasma samples were drawn from a radial arterial catheter inserted prior to the study period and analyzed for (18 F)-FDG activity as well as glucose concentration as required by the model for quantification of metabolic rates. Section scans were started 30 minutes after the FDG injection. Each scan took 10-14 minutes depending on the count rate, and 6-8 section scans were obtained at 1cm levels through the region of interest of the brain. The subject's head was positioned such that the scan plane was parallel to the orbital-meatal (OM) line. Cerebral metabolic rate is correlated with density such that light areas in the tomograph correspond to areas of high glucose utilization resulting from neuronal activity in the brain.

In this investigation connected discourse was presented to six experimental subjects: three via the right ear and three via the left. Two control subjects wore the headset but did not receive the auditory signal. The results for all six experimental subjects demonstrated greater tomograph density in the right hemisphere temporal cortex compared to the left hemisphere at OM + 4cm. Also, measurements of metabolic rate for glucose ranged from 15 to 32% greater for the right temporal cortex compared to the homologous region of the left hemisphere. The most striking hemisphere differences, however, were seen in the tomograph scans whereby the entire right temporal cortex displayed greater metabolic activity in contrast to the left. The tomographic scans for the control subjects displayed essentially symmetrical temporal cortex activity in contrast to the experimental group.

The findings of this investigation are discussed as they relate to other recent evidence concerning the receptive linguistic capability of the right cerebral hemisphere.

"PERCENT HEARING LOSS: WHAT YOU SEE AIN'T WHAT YOU GET" By Neil Ver Hoef

Allan Heffler authored an article called "Workmen's Compensation for Hearing Loss//Pandora's Box?" in the July/August issue of Occupational Health and Safety. He presented an excellent review of the legal aspects of compensable hearing loss. I'm going to refer you to that article and concentrate this presentation on various methods used in calculating percent hearing loss, impairment, disability or handicap. For a comprehensive definition of those terms, see the May 11, 1979 issue of the Journal of the American Medical Association.

Since the invention of the so-called "electric audiometer", and the first published audiogram in 1922, percent hearing loss has been studied and reported; in fact, the first audiograms were rated as percent of dynamic range by frequency. With the adoption of the decibel notation, Fletcher proposed a "point eight" rule for conversion to percentage in 1929. By 1942 and 1947 the studies by Sabine and Fowler were adopted as guidelines for estimating hearing loss in percent by the A.M.A. Suggestions for change to a simplified formula were made as early as 1951, and by 1959, the so-called AAOO formula was adopted and has remained as the most popular scheme until last May.

1) For those who have forgotten, those who weren't around, a quick look at the 1947 Fowler-Sabine scale as published in the JAMA. For each of the test frequencies of 512, 1024, 2048, and 4096 Hertz, or cycles-per-second, a percent value was placed on hearing levels at five decibel increments. After finding the thresholds for each ear, the scaled percent values were extrapolated to a table on the side of the graph for cumulation of the total percent hearing loss for each ear. Youngsters will note that the left ear threshold was marked with a circle and the right ear with a cross in those days.

2) The scheme encompassed two important concepts: (1) test frequencies were of different relative importance to the hearing and understanding of speech, and (2) the total percent loss of hearing is the sum of each of the values.

3) The sampling strategy, simply stated, was to measure hearing thresholds in the middle of each of four octaves bounded by 362 Hertz at the low frequency end and by 5792 Hertz at the high frequency end. The center frequencies corresponded to the audiometric test frequencies available on standard audiometers of the time.

4) The boundaries are shown on this log-scale audiogram which has been converted to ANSI values.

5) The AAOO formula, published in 1959,

6) Includes the frequencies 500, 1000, and 2000 Hertz; thresholds are averaged, a "low fence", or level of beginning of impairment of 25 decibels is subtracted, and the excess is multiplied times a 1.5% factor.

7) The band-width, if the test frequencies are considered as the center frequencies of each octave, extends from 353 to 2828Hz,

8) Shown here in comparison with the 1947 scale.

9) Here is an audiogram which would be commonly associated with a noise-induced hearing loss; the steeply sloping high frequency loss averages 25 decibels for 500, 1000, and 2000 Hz - right on the "low fence" -- thus, no excess or percent hearing loss. It is difficult to tell the patient in one breath to try hearing aids and in the next, tell him he has no compensable hearing loss.

10) The fallacy, of course, is the absurd notion that the good hearing above the low fence at 500 Hz somehow compensates for the poor hearing below the low fence at 2000 Hz.

11) Retrospective eyeglasses which I wear, results in 20/20 hindsight and reveals the problem as inappropriate averaging of decibel hearing levels.

12) While over simplified, we see the importance of different ranges for different speech-hearing functions.

13) Schemes for modification of the basic formula add to the distortion of the illegitimate average.

14) A proposal in 1971, a modification by subtracting the low fence from each test frequency then averaging the excess was adopted by the Office of Worker Compensation Federal Dept. of Labor.

15) Using the same numbers from the sample audiogram, there is somewhat of a percent hearing loss using this modification.

16) An even greater percent loss is obtained if one uses the legitimate averaging process of converting the decibels to ratios, averaging the ratios, then converting back to decibels.

17) The National Institute of Occupational Safety and Health, in 1972, proposed that the average hearing

18) Levels for 1000, 2000, and 3000 Hz is a better criterion for hearing impairment caused by noise, and suggested those frequencies be used in the basic AAOO formula.

19) The test frequencies are not of equal band-width; 3000 Hz samples a 42% band, 2000 Hz samples 51%, and 1000 Hz samples 70%, or an octave. The AAO 1979 formula adds another octave on the low end.

20) Schemes for evaluating efficiency of test booths demand equal weight to each test frequency,

21) As do formulas for calculating attenuation of hearing protection devices.

22) Applying the same reasoning to hearing loss, here is what we have come to call the Iowa Method for determining percent hearing loss for worker compensation purposes.

23) The important portion of the speech range is divided into three equal octaves. Each contributes one-third to the total percent loss. The low frequency octave covers 400 to 800 Hz, the mid-frequency octave from 800 to 1600 Hz, and the high frequency octave from 1600 to 3200 Hz. The corresponding center frequencies are 565, 1130, and 2260 respectively.

24) Next, you can see that each octave can be sampled by two standard audiometric test frequencies, each 32% or one-half octave wide. Average hearing level of the band is the average of the two test frequencies.

25) For the low frequency band, 500 and 750 Hz are used, and a low fence of 25 decibels is subtracted from the average to find any excess; a percent factor of .5% is multiplied times the excess to determine the percent loss for the band.

26) For the mid frequency band, tests at 1000 and 1500 are used to find the average, and the same procedure is followed to determine the percent for the band;

27) And for the high frequency band, 2000 and 3000 Hz test frequencies are used in the same manner.

28) Again, referring to the sample audiogram, for the right ear

29) The low frequency band nets zero percent,
30) The mid-frequency band shows a 5% loss, and
31) The high-frequency band shows a 15% loss

32) Which, when added together,
33) As in this worksheet, totals 20% loss for the right ear.

34) Here is our patients audiogram again...what you see.

35) Here is how it looks on the log-scale audiogram as the sloping loss cuts through the various frequency ranges.

36) The range above the low fence is really no bonus, and is probably a liability; the hash marks show the area lost in the Iowa Method, and the broken lines indicate the area of loss for the Sabine-Fowler, AMA 1947 scale.

37) Here's what you get: AAOO, 0%

AAO 13.125%
Iowa 20%
NIOSH 30%
AMA-1947 37.3%

For what it is worth, I think we may be on the right track to consider ranges by band-width of equal value, sampled by more than one test frequency, and a sum of the bands rather than an illegitimate average.

A Eulogy to Philip E. Rosenberg

May 22, 1979

SOME OF OUR RICHEST DAYS ARE THOSE IN WHICH NO SUN SHINES OUTWARDLY, BUT SO MUCH MORE SHINES INWARDLY. THIS IS ONE OF THOSE DAYS, FOR OUR MUCH LOVED FRIEND AND RESPECTED COLLEAGUE IS GONE. MY FRIEND OF THIRTY YEARS HAS PASSED THROUGH THE DOOR SERENELY AND WITH DIGNITY ON STILL ANOTHER NEW EXPERIENCE WHICH SOMEDAY HE WILL SHARE IN HIS SPECIAL WAY WITH ALL OF US. HE HAS LEFT US ALL WITH MEMORIES --THOSE WONDERFUL THINGS THAT BRIGHTEN OUR LIVES.

I REMEMBER HOW HE NESTLED LOVINGLY IN THIS WORLD; HOW HE CLIMBED ITS MOUNTAINS, ROAMED ITS FORESTS, SAILED ITS WATERS, CROSSED ITS DESERTS; HOW HE FELT THE STING OF ITS FROSTS, THE OPPRESSION OF ITS HEATS, THE DRENCH OF ITS RAINS, THE FURY OF ITS WINDS; HOW HE TASTED ITS PLEASURES AND ITS SORROWS, AND I REMEMBER HOW HE SAW HUMOR IN EVERYTHING.

PHIL FIRST TOUCHED MY LIFE IN 1949 GENTLY AND INDELIBLY AS WAS HIS MANNER EVEN THEN. ONE OF MY EARLY MEMORIES OF HIM WAS AS A BLACK-FACED GANGSTER IN THE UNIVERSITY OF MARYLAND THEATER PRODUCTION OF "PETRIFIED FOREST". THERE ARE OTHERS OF YOU HERE WHO WILL REMEMBER THOSE LONG AGO THEATER DAYS, AND PERHAPS YOU CAN RECALL AS I CAN THAT EVEN FIERCE THEATER MAKE-UP COULD NOT DULL THE GENTLENESS IN HIS EYES. HE LOVED THE THEATER WITH ITS MAKE-BELIEVE, BUT HE LOVED REALITY MORE, AND HE LIVED HIS LIFE REAL AND TO THE FULLEST.

HE BECAME MY CAMPUS FRIEND, MY SAGE, MY CONFIDANTE -- AS HE DID TO SO MANY IN THE YEARS THAT FOLLOWED. I REMEMBER WE LAUGHED A LOT EVEN IN THOSE EARLY YEARS AND LAUGHTER BECAME THE HALLMARK OF OUR RELATIONSHIP.

WE SPENT TIME TOGETHER AT THE ARMY AUDIOLOGY AND SPEECH CENTER OF WALTER REED -- PHIL AS A SOLDIER AND A GRADUATE STUDENT, AND I AS A CIVILIAN AND AN AUDIOLOGY TRAINEE. I REMEMBER THE SIGHT OF HIM AT EARLY MORNING ROLL CALL, A MIXTURE OF OBEDIENCE AND MISCHIEF WITH HIS GREAT ARMY OVERCOAT PULLED TIGHTLY ABOUT HIS CHIN TO HIDE THE COLLAR OF HIS PAJAMAS STILL WORN UNDERNEATH, -- STILL WARM FROM SLEEP. A CIVILIAN SOLDIER WE CALLED HIM, OUR SECRET WEAPON IN COMEDY DISGUISE. WE LAUGHED ABOUT IT THEN -- I SMILE AT THE MEMORY EVEN NOW.

WE COLLECTED AUDIOMETRIC DATA ON HUNDREDS OF TUBERCULAR PATIENTS AT THE OLD GALLINGER MUNICIPAL HOSPITAL IN WASHINGTON, D.C., AND BEHIND THE PROTECTIVE MASKS WE WORE IN THAT CONTAGIOUS WARD WE LAUGHED AT THE SIGHT OF US IN ILL-FITTING HOSPITAL GOWNS. WE DRANK TOGETHER IN THOSE DAYS, WE DOUBLE-DATED IN A 1947 PLYMOUTH. WE FREQUENTED PLACES IN THE NATION'S CAPITOL LONG SINCE REPLACED BY THE METAPHORS OF PROGRESS, AND FROM IT ALL I HAVE THE MEMORY OF A TIME MADE BETTER BY THE FRIENDSHIP OF A GENTLE MAN.

WE LEARNED MUCH TOGETHER IN THOSE EARLY YEARS ABOUT THE DISCIPLINES OF A PROFESSION, THE ORDERLY PROCESSES OF SCIENCE, AND ABOUT OUR GOALS. AND AS SO OFTEN HAPPENS GOALS DRAW CLOSE FRIENDS TO DIFFERENT GEOGRAPHIES, TO NEW EXPERIENCES. AND SO IT WAS WITH US. BUT HIS LETTERS WERE BRIGHT SPOTS. SERIOUS, YET COMICAL WHEN THE OCCASION WARRANTED. HE USED THE VOCABULARY OF OUR FIELD PRECISELY AND THE LANGUAGE OF OUR LAND EXQUISITELY.

WHEN INNER TURMOIL TORMENTED HIM HIS OUTWARD COUNTENANCE WAS ONE OF PEACE, HIS VOICE FIRM AND CONFIDENT. THOSE OF YOU WHO VISITED OR SPOKE WITH PHIL DURING THESE PAST 2½ MONTHS CAN SHARE THE WONDER OF THAT RECENT MEMORY WITH ME.

A FEW SHORT WEEKS AGO, I SAT WITH PHIL IN HIS LIVING-ROOM SOON AFTER HE HAD BEEN TOLD THE SERIOUSNESS OF HIS ILLNESS. THE VISIT SEEMED SOMEHOW EASIER FOR HIM THAN ME AMONG THE TALK OF MIRACLES AND REALISMS WE HIT UPON AN INCIDENT INVOLVING THE GENTLEMAN WHO IS PHIL'S FATHER-IN-LAW. AS THE DETAILS OF THE DETECTIVE AND THE TEENAGED OFFENDER UNFOLDED WITH SURPRISE AND LAUGHTER IN THAT LIVING-ROOM, THE BRIGHTNESS OF ENJOYMENT SPARKLED IN PHIL'S EYES. IN THE MIDST OF HIS OWN LIFE-TAKING NEWS HE SAID, "THAT'S THE MOST INCREDIBLE THING I'VE EVER HEARD," AND HE GAVE THAT FUNNY LAUGH OF THIRTY YEARS AGO.

A CLOSE AND DEAR FRIEND WHO VISITED WITH HIM A FEW WEEKS AGO SHARED WITH ME SOME OF HIS CONVERSATION. HE SPOKE OF HOW MUCH HE HAD LEARNED ABOUT HIMSELF AND ABOUT OTHER PEOPLE DURING HIS ILLNESS -- ABOUT ACTIONS AND REACTIONS TO KNOWING DEATH IS NEAR. HIS DIGNITY AND CLASS CAME THROUGH. HE SAID, "I WOULDN'T HAVE MISSED IT FOR THE WORLD."

HE TOUCHED THE LIVES OF US ALL, GENTLY AND INDELIBLY, AND SOME OF OUR RICHEST DAYS ARE THOSE IN WHICH NO SUN SHINES OUTWARDLY, BUT BECAUSE OF HIM SO MUCH MORE SHINES INWARDLY. I SENSE HIS PRESENCE -- HE WOULDN'T HAVE MISSED THIS FOR THE WORLD. AND I SENSE, TOO, THAT ONE DAY I SHALL LAUGH ONCE MORE WITH MY FRIEND.

David Resnick

BOOK REVIEW

Continued report on Acoustic Tumors by William F. House and Charles M. Luetje

by Robert Mischke
Denver, Colorado

Volume II: Management

This volume begins with anesthetic considerations, discussing preoperative, intraoperative and postoperative management. Out of 251 patients, 5.6% suffered some postoperative pulmonary difficulty. Controlled ventilation is preferred. Large doses of narcotics should be avoided. Closed observations continues for 6 to 8 hours postoperatively.

The middle cranial fossa approach to tumors is used for removal of small acoustic tumors in an attempt to preserve hearing. In an only-hearing ear, tumors large enough to extend outside of the internal auditory canal may also be approached through the middle fossa. The technique is beautifully illustrated and discussed.

The translabyrinthine approach is preferred for tumors outside the internal auditory canal, including larger tumors, reasoning that a higher percentage of facial function is preserved with this approach. The supine position is preferred for surgical access as well as reducing hazard of air embolism. Two-staged removal is used primarily just when necessary due to vital signs changes. The surgical technique of tumor removal using the translabyrinthine approach is discussed and illustrated in great detail.

Presentation of facial functions was studied through patient questionnaires, allowing the patient to be critical of any weakness. 229 of 444 (51.6%) responding indicated some weakness for one year or more postoperatively. This represented 20.8% of small tumors, 44.5% of medium tumors, and 69.6% of large tumors.

Complete facial paralysis was present in 13.5% with 0% of small tumors, 10.4% of medium tumors, and 21.4% of large tumors.

Hypoglossal facial anastomosis was required in 22 of 500 cases. If the facial nerve has been interrupted surgically, the anastomosis should not be done for at least one year. The technique is described.

Eye problems associated with facial paralysis are discussed for both temporary prolonged situations. Medical and surgical management is recommended.

Preoperative and postoperative medical evaluation is outlined as well as nursing instructions and nursing care.

The psychology of surgery is reviewed and the point is made that the patients do better if they are given realistic information prior to surgery.

Long term effects of hearing loss is discussed including the use of a CROS hearing aid when appropriate. The long term follow-up of vestibular effects revealed that compensation for the deficit is never complete, although the subjects consider themselves normal.

The operative mortality was 2.6% for the 500 cases. The cases are reviewed. All but one of these cases were large tumors.

Partial removal is considered in some patients, such as with severe cardiorespiratory disease, change in vital signs, or advanced age. However total removal should be strived for because residual tumor and repeat operation is hazardous if the patient lives more than 6 years.

In summary, both volume I and volume II of Acoustic Tumors represent the most comprehensive discourse on diagnosis and management of this malady. Dr's. House and Luetje are congratulated.

The New ACO Criteria for Industrial Audiometry

The American Council of Otolaryngology (ACO) have developed new criteria and procedures for audiometry and occupational hearing conservation programs to clarify the kinds of problems that should be referred to otolaryngologists.

According to the new regulations, workers whose audiograms show a change of more than 15 dB at 500, 1000 or 2000 Hz more than 20 dB at 3000 Hz and more 30 dB for 6000 Hz should be referred to a specialist for examination. When comparing previous or baseline audiogram with a monitoring audiogram the elapsed time between testing should be no more than two years.

Referral should also be made to a specialist when the average hearing level is greater than 30 dB at 500, 1000, 2000, 3000 Hz, when there is a single frequency loss greater than 5 dB at 3000 Hz or greater than 30 dB at 500, 1000 or 2000 Hz; when there is a difference in average hearing level between the better and poorer of more than 15 dB at 500, 1000, and 2000 Hz or more than 30 dB at 3000, 4000 and 6000 Hz, and unusual hearing loss curves or inconsistent responses. The Council recommends that testing should be performed by a certified audiologist using equipment that meets ANSI standards and fills ANSI requirements for the proper environment.

Direct referrals should be made to an otolaryngologist in the presence of persistent ear pain, drainage, dizziness, severe persistent tinnitus, fullness or discomfort in either or both ears, or a history of any of these problems in the past year.

Also, visible evidence of cerumen accumulation or a foreign body in the ear canal requires direct referral. Whenever a worker develops ear pain, drainage, dizziness, or severe persistent tinnitus, or shows a significant change in the hearing levels he should be reexamined. Complete copies of these new ACO rulings may be obtained from: American Council of Otolaryngology, Suite 602, 1100 17th Street, N.W. Washington, D.C. 20036.

RECOVERY OF SUPRATHRESHOLD AUDITORY TEST
FUNCTION AFTER REMOVAL OF C.P.A. TUMOR

Thomas M. Watkins
Fort Gordon, Georgia
G. Richard Holt
Milton G. Yoder
John McCloskey

Recovery of eighth nerve function after C.P.A. tumor removal has been reported by other authors, but none have utilized the pre-and post-therapy diagnostic battery of suprathreshold auditory testing. Two cases are presented, one a medulloblastoma, and the other an acoustic schwannoma in which there was recovery of function in a variety of threshold and suprathreshold tests.

Case #1: A twenty-six-year-old male presented with a right sided hearing loss and signs and symptoms of a right C.P.A. tumor. CAT scan revealed a 5 cm mass in the right C.P.A. At craniotomy, a malignant medulloblastoma was found and subtotally resected. Suprathreshold audiometric special test procedures were monitored sequentially before surgery, after surgery, during radiotherapy, and following radiotherapy. The auditory procedures of choice include a Suprathreshold Adaptability Test (STAT), Performance Intensity of Phonetically Balanced Words (PIPB), Crossed Acoustic Reflexes (CAR), Bekesy Comfortable Loudness Tracings (BCL), and Synthetic Sentence Identification (SMI-CCM-ICM). Auditory Brain Stem Evoked Response Measures (ABSER) were auditory parameters demonstrating retrocochlear indications preoperatively and postoperatively during radiotherapy to the whole head, spine and posterior fossa. However, these results reversed to cochlear indications two months following the initiation of radiotherapy. The treatments consisted of 4,000 rads to the whole head, 1,000 rads to the posterior fossa, and 3,200 rads to the spine. Pure tone thresholds remained relatively unchanged regardless of conditions. The patient continued to manifest a mild sensorineural hearing loss bilaterally, the involved ear being slightly worse than the noninvolved ear. Those special tests which demonstrated recovery include STAT, CAR, PIPB and BCL. ABSER measures obtained three months and ten months post-treatment revealed clearly defined wave I-V with normal latencies from monaural stimulation of the non-involved ear. Monaural stimulation from broad band click stimuli presented to the involved ear resulted in the appearance of waves I and II at normal latencies. No measurable activity following wave II was present, either three months or ten months post-treatment. In adult medulloblastoma, the prognosis is poor, with a 30% chance of five-year survival. The biochemical or mechanical mechanisms underlying the recovery of auditory parameters are speculative. The tumor mass may have created pressure on the eighth nerve trunk causing nerve edema interfering with the first order neuron transmission and producing retrocochlear manifestations. Surgical decompression of the nerve combined with irradiation of the tumor-surrounded (or invaded) nerve probably served as the mechanism to restore partial acoustic function.

Case #2: A twenty-one-year-old male was referred for dizziness, ataxia, and hearing loss. He had no demonstrable hearing in the right ear and decreased hearing in the left ear. CAT scan revealed an 8 cm tumor on the right side. A craniotomy was performed and a large, right acoustic schwannoma to the pathology. Special audiometric suprathreshold test procedures were monitored on the contralateral to the pathology. Special audiometric suprathreshold test procedures were monitored on the ear contralateral to the alateral to the pathology. Special audiometric suprathreshold test procedures were monitored on the ear contralateral to the pathology. Special audiometric suprathreshold test procedures were monitored on the ear contralateral to the pathology. Test procedures included STAT, PIPB, CAR, and ABSER. All test procedures were obtained before surgery and two months following surgery. ABSER was available after surgery only. Two procedures indicating possible retrocochlear pathology demonstrated some degree of recovery postoperatively. Low frequency pure tone thresholds improved postoperatively. Performance Intensity of Phonetically Balanced Words also improved postoperatively although PIPB rollover index remained abnormal. ABSER obtained four and six months postoperatively revealed no measurable response on the ipsilateral ear and the appearance of wave I only from monaural stimulation of the contralateral ear. The mechanism underlying the recovery of pure thresholds and PIPB on the contralateral ear are speculative in this case. There was no evidence of other pathology in the contralateral ear other than displacement of the brain stem from the relatively large tumor mass. This displacement could have affected the contralateral cochlear nuclei and eighth nerve, producing an abnormal rollover index and low frequency sensorineural hearing loss. The release of pressure from the brain stem and contralateral eighth nerve may be the mechanism underlying the recovery of certain auditory parameters.

(Cont. on pg 15)

All You Wanted To Know About Hearing Dogs

Hearing Dog, Inc., whose staff was formerly with American Humane Association's Hearing Dog Program, is a non-profit organization solely devoted to training dogs for the deaf. Although it costs Hearing Dog, Inc. \$2500 to train and place a dog, the dogs are free of charge to the deaf.

Agnes McGrath, master trainer, is the originator of training methods used today. She did a feasibility study in 1975 through the Minnesota Society for the Prevention of Cruelty and has been involved with the training of hearing dogs since that time. Martha Foss, master trainer, has been involved with all methods of dog training including search and rescue, and has added her expertise in training of hearing dogs for the last three years. Sandi Kilstrup, who was taught training methods by Agnes and Martha, is an audiologist who has worked in clinical rehabilitation and research with the hearing-impaired. She has trained hearing dogs for the past two years.

The staff also includes an R.N. who is the kennel manager, and a secretary whose background is in deaf education. All members of the staff manually communicate.

The training begins with the selection of dogs from animal shelters. The dogs must be healthy, happy, and intelligent...with a special ability to please and work for people. Over a period of three months, they are trained in auditory awareness and obedience. The sounds they are trained for include doorknock/doorbell, security buzzer, smoke alarm, alarm clock, telephone, baby cry, and unfamiliar sounds which may indicate danger or some other emergency to the deaf owner. Basic obedience is necessary as there are currently twenty-five states which allow the hearing dogs the same rights as dog guides for the blind.

Hearing dogs have been placed with deaf people from the ages of 17 to 84. Those who are not living with hearing people and who have no other dog, are of priority, as they have the greatest need.

Hearing Dog, Inc. relies solely on donations from the public to have the program continue. Agnes, Martha, and Sandi all have their own trained hearing dogs and will be glad to demonstrate how a hearing dog works. Also available is a slide presentation which shows the facilities of Hearing Dog, Inc., and the dogs in action. Those interested in donating, applying for a hearing dog, or wishing a demonstration, please write to Hearing Dog Inc. 5901 E. 89th Ave.

Aspen-Snowmass Conference a Grand Success

Charles P. Lebo, M.D.

Darrel L. Teter, Ph.D.

Guest of Honor Prof. L.B.W. Jongkees of Amsterdam, Netherlands visits with James W. (Wally) Wolfe, Ph.D.

F. Owen Black, M.D.

Frederick H. Linthicum, Jr. M.D.

Donald B. Kamerer, M.D.

David N. Resnick, Ph.D.

Dennis G. Pappas, M.D.

An enthusiastic group of over 100 otolaryngologists and audiologists took part in the Aspen-Snowmass Conference on Vestibular Disorders the week of August 20th in Snowmass, Colorado.

The conference, organized by Darrel L. Teter, Ph.D., of Denver, Colorado, in conjunction with Tracoustics, Inc. in Austin, Texas, featured Professor L.B.W. Jongkees, M.D., and a distinguished faculty.

Professor Dr. L.B.W. Jongkees, whose wife accompanied him on the trip, from Amsterdam, Netherlands, was joined on

the faculty by Dennis G. Pappas, M.D., F. Owen Black, M.D., Jack D. Clemis, M.D., Charles W. Stockwell, Ph.D., Frederick H. Linthicum, Jr., M.D., James W. Wolfe, Ph.D., Buck C. Brown and David M. Resnick, Ph.D. Each member of the faculty made presentations on two topics and all joined in lively round table discussions of current techniques, application and research in treatment of disorders of the vestibular system.

Meetings were interspersed with activities such as a mountain hayride and cookout, trout fishing, hiking and

swimming, enhanced by beautiful summer weather in the Colorado Rockies.

In response to inquiries following the Conference, the Coordinating Committee of Darrel L. Teter, Ph.D., Jerry Northern, Ph.D., and Charlie D. Anderson, President of Tracoustics, Inc., will announce dates for the 1980 Aspen-Snowmass Conference within the next few weeks.

The Conference will again be administered by Tracoustics, Inc., of Austin, Texas, and inquiries should be directed to the toll free number 1-800-531-5412.

Tracoustics Holds Sales Meeting

Tracoustics Second Annual Super Summer Sales Seminar...fun time.

Tracoustics Representative (left) and Karl Brandmaier of AudioMed, Inc. (right) admire the Summer Sales Meeting T-Shirt held by Charles Enz of Medacoustics. Kurt Trede of Tracoustics/Denver is otherwise engaged.

Tracoustics' Anderson (l) gives award for Highest Sales to Karl Brandmaier of AudioMed, Inc., Santa Fe Springs, CA.

Charlie D. Anderson, President of Tracoustics, congratulates award winner R. J. Baird of Raytown, MO.

TRACOUSTICS representatives from across the United States and Canada gathered in Austin, Texas October 5th through 6th for the Second Annual TRACOUSTICS Summer Sales Seminar. The seminars provide a continuing education program on new clinical developments and on Tracoustics new products for the hearing health care professions. They also serve as a forum for ideas and suggestions which continue to improve the company's products and service.

A group of 48 TRACOUSTICS representatives and staff

members gathered at the company's Austin office and manufacturing facility for a plant tour on Friday morning, and then adjourned to the Travelodge for day-long sessions which included a workshop on ENG techniques, discussions of current audiological assessment, and new developments in the audiometric room design.

The two days of extensive presentations ended with an informal Awards Banquet where Tracoustics President, Charlie D. Anderson, recognized Russ Baird of R.J. Baird and

Associates, Raytown, Missouri, as representative with sales most exceeding quota, based on population, and gave an award to AudioMed, Inc., of Santa Fe Springs for largest total sales volume. For the second consecutive year Karl Brandmaier of AudioMed accepted a plaque for this award.

Everyone was given a Tracoustics Sales Seminar T-shirt complete with armadillo design, which most wore on the chartered bus which took the group to Dallas for the American Academy of Otolaryngology Annual Meeting.

EFFECTIVENESS OF RESCREENING IN A SCHOOL HEARING CONSERVATION PROGRAM FOR CONDUCTIVE HEARING LOSS

R.J. Pellerin
and

J.C. Cooper, Jr.
Division of Otorhinolaryngology
University of Texas Health Science Center
San Antonio, Texas

Impedance measures have demonstrated their value in detecting middle ear pathology. Because conductive hearing loss is a major threat to young children, a variety of reports have advocated the use of impedance screening in hearing conservation programs. However, such use has not been without criticism. A major problem has been over-referral and at least one report has proposed rescreening to reduce its magnitude. A second issue has emerged as a byproduct of the availability of a rapid, easily applied screening technique. That is the assertion that different racial groups have different rates of middle ear disorders. The following investigation had two purposes: 1. to shed light on screening criteria by examining the pattern of results on re-screening. 2. to compare black children to hispanic children in order to determine if there are any differences in the indicators of middle ear pathology between the two groups.

Information in this report was taken from ongoing screening program within the San Antonio Independent School District in which over 17,000 children were screened with impedance audiometry and a 4 k Hz pure tone at 25 dB HL during the 1978-79 school year.

Our findings reinforce, on a larger scale, the demonstration by Lewis, Dugdale, Canty and Jerger (1975) that single impedance measures are unlikely to give an efficient index of the probability of chronic, medically attendable middle ear dysfunction. At approximately the same time, we (Cooper, Gates, Owen and Dickson, 1975), cautioned those using impedance technique for screening that it was likely to result in a significant over referral rate. In both reports, premature referral would occur when initial screening produced a "C" tympanogram.

In conclusion, we feel that the present data permit the following two admonitions to be made to those employing impedance technique.

First, an accurate picture of middle ear condition is unlikely if based on a single measure when that measure suggests negative middle ear pressure. This is true in either an ongoing hearing conservation program or when purporting to describe the incidence of middle ear pathology.

Second, careful analysis of the relationship between degree of negative middle ear pressure and likelihood of spontaneous recovery is still needed before firm referral criteria can be developed for hearing conservation programs.

Central Auditory Dysfunction conference announced

The University of Cincinnati Medical Center will sponsor a 3-day symposium on Diagnosis and Remediation of Central Auditory Dysfunction in Children. The course will be held at Stouffer's Inn in Cincinnati on May 28, 29, and 30, 1980. The purpose of the symposium is to provide a forum for the meaningful exchange of current information and ideas on the diagnosis of and therapy techniques for central auditory disorders in children. To accomplish this end, the conference will comprise formal presentations by invited faculty, including Norma Rees, Katharine Butler, Sylvia Richardson, and Robert W. Keith. Shorter papers submitted by participants, panel discussions, and workshops intended to promote audience participation, and exhibits by publishers and equipment manufacturers will also be incorporated. Persons wishing to present a paper should submit a 400-600 word summary. Application has been made for 16 credit hours in Category I of the Physicians Recognition Award of the American Medical Association. For further information about the symposium or details on submitting papers for presentation, contact:

Dorothy H. Air, Ph.D.

Tracoustics delivers first Program III audiometer

The first production model PROGRAM III Clinical Audiometer, manufactured by TRACOUSTICS, Inc., was recently delivered to the University of Colorado Medical Center in Denver, Colorado. Marion Downs, M.A. and Jerry Northern, Ph.D., whose suggestions helped to shape the design and programming of the audiometer, accepted delivery of the instrument at the Department of Audiology.

TRACOUSTICS elicited suggestions from leaders in the field of clinical audiology as to what characteristics are most important for current clinical procedures. Frederick N. Martin, Ph.D., and Darrel L. Teter, Ph.D. were also among

those whose comments influenced the instrument design. Buck C. Brown, head of TRACOUSTICS Instrument Division, was responsible for incorporating these clinical criteria into electronic design and computer programming of the microprocessor-based audiometer.

Among the facilities which will receive early production-model PROGRAM III audiometers are Topeka Public Schools - Department of Public Services, Louisiana State University, Gunderson Clinic, VA Medical Center - Jackson, Mississippi, and Brigham Young University, along with a number of private Otolaryngology practices.

"I really shouldn't be here. I should be out trying to get funded."

PROGRAM SET FOR ANNUAL AAS MEETING

A. Bruce Graham, program chairman, announced the appointment of Michael Papparella and Bill Ely as co-chairmen of the 1980 annual meeting of AAS to be held on November 20th at the Henry Ford Hospital in Detroit, Mich. The theme of this year's meeting is "The Hearing Impaired: Rehabilitation Roots", and a full day of invited and solicited papers is being planned. Further details of the meeting will appear in the Spring issue of Corti's Organ.

CALENDAR OF EVENTS

1980
JANUARY 19-20

ADVANCED ELECTRONYSTAGMOGRAPHY, Orlando, FL. 16 hours, Category II AMA Credit. A course designed to sharpen the technical and interpretative skills of the experienced electronystagmographer by reviewing test procedure, nystagmus quantification and tracing interpretation. Contact: Life-Tech Instruments, Inc., P.O. Box 36221, Houston, TX 77036, 713-783-6490.

FEBRUARY 9-16

FOURTH ANNUAL MID-WINTER SYMPOSIUM ON PRACTICAL OTOTOLOGY, Snowmass (Aspen), Colorado. Sponsored by: American Hearing Research Foundation. Contact: Jack D. Clemis, M.D., Program Chairman, American Hearing Research Foundation, 55 East Washington Street, Suite 2105, Chicago, Illinois 60602.

MARCH 1-8

14TH ANNUAL COLORADO OTOTOLOGY-AUDIOLOGY WORKSHOP, Vail, Colorado. Contact: 14th Colorado Otolaryngology-Audiology Workshop, Box B210, 4200 E. 9th Avenue, Denver, CO 80262 or call toll-free 800-323-0639.

JUNE 21-25

REHABILITATION THROUGH AMPLIFICATION WORKSHOP, Chicago, IL. Sponsor: American Hearing Research Foundation, AMA Category I credit. Contact: Jack D. Clemis, M.D., Program Chairman, American Hearing Research Foundation, 55 East Washington Street, Suite 2105, Chicago, Illinois 60602. Phone: (312) 726-9670.

22-27

14TH WORLD CONGRESS OF REHABILITATION INTERNATIONAL, Winnipeg, Canada.

JULY 9-16

TENTH INTERNATIONAL CONGRESS ON ACOUSTICS, Sydney, Australia. The Congress will explore the future of acoustics in its many aspects. Contact: 10 ICA Congress Secretariat, GPO Box 2609, Sydney, NSW, Australia 2001.

AUGUST 4-7

18TH CONGRESS OF THE INTERNATIONAL ASSOCIATION OF LOGOPEDICS AND PHONIATRICS, Washington, D.C. Contact: Frances J. Johnston, Ph.D., IALP Congress, 10 Rockville Pike, Rockville, MD 20852, 301-897-5700.

4-8

INTERNATIONAL CONGRESS ON EDUCATION OF THE DEAF, Hamburg, West Germany. Contact: S. Richard Silverman, Ph.D., Central Institute for the Deaf, 818 S. Euclid, St. Louis, MO 63110.

SEPTEMBER 2-6

XV INTERNATIONAL CONGRESS OF AUDIOLOGY, Krakow, Poland. To submit papers or register, write to: Andrzej R. Halama, Kopernika 23a, 31-501 Krakow, Poland.

NOVEMBER 20

ANNUAL MEETING OF THE AMERICAN AUDITORY SOCIETY, Detroit, Mich. Contact: A. Bruce Graham, Program Chairman, Henry Ford Hospital, Detroit, Mich.

1981
JUNE 21-27

12TH WORLD CONGRESS OF OTOTOLOGY-PHONOLOGY, BUDAPEST, HUNGARY. Write to: Professor Dr. L. Surjan, P.O.B. 112, Budapest, Hungary H-1389.

AMERICAN ACADEMY OF OTOLARYNGOLOGY ELECTS 1980 OFFICERS

DALLAS.—New officers of the American Academy of Otolaryngology were elected at its 1979 Annual Meeting, which was held Oct 7-11 at the Dallas Convention Center. Over 3,000 attended scientific presentations and continuing education courses on the latest research in otolaryngology and head and neck surgery.

Jack R. Anderson, MD, of New Orleans will take office as President of the Academy on Jan. 1, 1980. The other elected officers are Bobby J. Alford, MD, of Houston, President-Elect; Paul H. Ward, MD, of Los Angeles, First Vice-President; Roger Boles, MD, of Stanford, California, Secretary of Program; D. Thane R. Cody, MD, PhD, of Rochester, Minnesota, Secretary of Instruction; George F. Reed, MD, of Syracuse, NY, Secretary of Continuing Education; Ralph J. Caparosa, MD, of Pittsburgh, Pennsylvania, Councillor (3-year term); and Loring W. Pratt, MD, of Waterville, Maine, Councillor (1-year term).

Wesley H. Bradley, MD, of Glenmont, NY, was approved as Executive Vice-President. He will serve as the Academy's primary administrative officer. A member of the Academy since 1953, Dr. Bradley is professor of Surgery (Otolaryngology) at Albany Medical College and chief of Otolaryngology Services at the Veterans Hospital, Albany, NY.

Dr. Anderson is clinical professor in the Department of Otolaryngology and Maxillofacial Surgery, Tulane University School of Medicine. Dr. Alford is chairman of the Department of Otorhinolaryngology and Communicative Sciences, Baylor College of Medicine. Dr. Ward is professor of Surgery and chief of the Division of Head and Neck Surgery (Otolaryngology), University of California at Los Angeles.

The American Academy of Otolaryngology is a postgraduate medical organization dedicated to advancement of the science and art of medicine as practiced by otolaryngologists. Its Headquarters are in Rochester, Minn. An otolaryngologist is a physician who specializes in the treatment and surgery of the ear, nose, and throat and related structures of the head and neck.

From those friendly Danes with that marvellous sense of quality.

If you are a small country like Denmark you can't afford to ask: "What does our insistence on quality cost us?" On the contrary we have learned to ask: "What would it cost us to send an inferior quality product on the world market?"

Thus we do not consider our rigid quality inspection an expense - but an investment.

Danavox dealers and service centers in 70 countries throughout the world know this perfectly well. It is, therefore, of more formal interest, that Danavox has extended its product warranty from one to two years.

CHABA Study Director Describes Function

(Editor's Note: For the generation of young professionals who are not acquainted with the work of the Committee on Hearing and BioAcoustics and Biomechanics of the N.A.S., the following article has been prepared. Dr. Milton Whitcomb is National Academy of Sciences' (NAS) Study Director, who has kindly written the following article for Corti's Organ. CHABA's next meeting will feature Tinnitus, Hearing and Aging, and Sports-related Injuries. The meeting date will be announced in the upcoming issue of Corti's Organ.)

COMMITTEE ON HEARING, BIOACOUSTICS, AND BIOMECHANICS (CHABA)

The Committee on Hearing, Bioacoustics, and Biomechanics responds to problems concerning any aspect of hearing. These problems involve engineering and equipment, the physics of sounds, physiology of response, individual perception, and group or social response. While the Committee deals chiefly with problems submitted by their sponsoring agencies, it also works on problems it generates, particularly on those that would be likely to interest the sponsors.

The Committee concerns itself with any field of science or technology that it finds necessary in pursuit of its objectives. These fields may include pertinent aspects of biological science, behavioral science, physics, chemistry, mathematics, engineering and medicine.

Examples of specific areas of interest to the Committee include:

- a. Hearing
 - (1) Measurement and evaluation of hearing.
 - (2) Conservation of hearing.
 - (3) The ear and associated central nervous system, its functions and means of protection against intense sounds.
 - (4) Communications, particularly speech communication in the presence of noise.
- b. Bioacoustics
 - (1) Non-auditory effects of intense sound fields on man and means for protection.
 - (2) Physiological, psychological and social reaction of man exposed to sound, for example, noise produced by jet-planes, rockets, gunfire, weapons, and vehicles.
 - (3) Physical and engineering problems of the generation, measurement and control of acoustical energy.
- c. Biomechanics
 - (1) Specification of the mechanical properties of the human body or its component parts.

(Continued on p.3)

Highlights of the AAS Executive Committee Meeting

The Executive Committee of AAS met in Detroit on November 20, 1980; the complete minutes of the meeting are given on page 5. The significant decisions made at the meeting are as follows:

- No dues increase in 1982
- Associate membership category is approved by the membership
- 1981 meeting to be held in New Orleans
- Awards to be given for outstanding manuscripts published in *Ear and Hearing*

Members are encouraged to read the minutes and contact Executive Committee members with any questions or comments.

Seidemann Outlines Annual Program

Mike Seidemann, program chairman for the 1981 annual meeting, has selected the Program Committee and is in the initial stages of planning for the presentations and events surrounding the meeting. This year's meeting will be held in New Orleans, La., in conjunction with the annual meeting of the American Academy of Otolaryngology-Head and Neck Surgery. The meeting date has been set for Monday, September 21, and the program theme is "Surgical and Prosthetic Management in Auditory Rehabilitation."

This year's meeting will be scheduled for the entire day (8:30 a.m.-5:00 p.m.). During the morning session invited papers will be presented, followed by the Carhart Memorial Lecture to be given by Dr. Paul Ward. Dr. Ward will present a paper entitled, "Research in Communicative Disorders: A Projection for the Next Decade." The afternoon session will feature submitted papers; a short business session will conclude the meeting.

A highlight of this year's meeting will be a riverboat tour of the New Orleans historic river front, to begin about 6:00 p.m. Complimentary cocktails and hors d'oeuvres will be provided. The traditional dinner for the Carhart Memorial Lecturer will follow the riverboat ride, and also promises to be exceptional. This year the dinner will be held in conjunction with the Society for Ear Nose and Throat Advances in Children (SENTAC) annual dinner. The dinner will be held at the internationally famous Commander's Palace restaurant, and during the festivities a real down-to-earth Cajun comedian will enliven the evening.

A Call for Papers will be sent in the next two to three weeks, and advanced registration will be included in the Spring issue of *Corti's Organ*. Those planning to attend the meeting this year are being encouraged to register as soon as possible, as there is room for only 120 participants. Other members of the program committee are AAS members: Virginia Anderson, George Cire, and Gerald Miltenberger.

Mike Seidemann

The major regulations involving limits to noise exposure for the protection of employees over the past years has been a maximum 90 dBA SPL level for eight hours with a 5 dB tradeoff, this being supplemented with vague references to use of ear protectors and monitoring hearing as "administrative" procedures (3). In January of 1974, a new OSHA draft in regard to noise was published (4). This was supposedly a final draft and included "a maximum exposure of 90 dBA for 8 hours with a 5 dB trade off" and permitted continued use of personal protective devices. It further stipulated that "if a significant shift in hearing develops (10 dB in speech range, 15 dB at 3KHz, and 20 dB at 4 and 6KHz) the employee must be notified and given a copy of his audiogram and referred for appropriate medical evaluation (4)." (Not much new here.) To say the least, these recommendations were not received with wild acclaim; support and damnation came from all quarters. The individual members of the OSHA committee issued statements almost weekly and everyone from industrial barons to neophyte audiometric technicians offered opinions. Research teams from far and wide offered "proof" that noise levels of 85 dB over prolonged periods resulted in damage to hair cells. Others intimated that you could whistle Dixie for twenty years at a 90 dBA level and not sustain a significant loss of hearing. The troops were engaged.

Dr. Meyers, then Deputy Assistant Administrator of noise programs of the Environmental Protection Agency (EPA) sounded the call to arms on March 11, 1975, at Lexington, Kentucky (5). He raised the banner of an 85 dBA eight-hour working day exposure and 3 dB tradeoff, and stated "EPA believes that technology in some form or other is available to control virtually any noise source." Also, that "there is no dispute anywhere that more people will have a permanent hearing impairment if they are exposed to 90 dBA for eight hours over a working lifetime, than if they were protected at the level of 85 dBA."

President Ford then seemed to express the opposition's position when he asked on April 28, 1975, at the 63rd annual meeting of the U.S. Chamber of Commerce, "Is it worth as much as 30 billion a year of consumers' dollars to reduce the level of occupational noise exposure by approximately five decibels? (6)"

The debate continued from that point on from convention meeting floors, called sessions, professional journals and trade organs.

Then came the public hearings — I'll not bore you with all the reports and counter reports, nor the multitude of recommendations. The total circus was well summarized in the August 14, 1975, issue of "Washington Sounds" (20).

After hearing hundreds of witnesses, the Occupational Safety and Health Administration (OSHA) on July 30 concluded its public hearings on occupational noise standards. But don't expect a standard soon. The scenario, which could stretch into next year, runs something like this: The hearing record will remain open for forty-five days for additional comments; then an inflationary impact statement must be prepared by OSHA and submitted for the record, a process that will go beyond the first forty-five day period; then an additional forty-five days will be allowed for public comment on the inflationary impact statement; and finally, after the hearing record closes, the agency has sixty days to prepare a final regulation. Those are just the scheduled events.

Given the controversy around this issue and the frequent delays in even getting hearings underway, it's possible that other events could intervene and further delay the timetable.

How true the prediction. We went into September 1975 thinking that the issue might be resolved with a compromise of 90 dBA and 5 dB tradeoff, but with stringent monitoring of hearing. However, by mid-September EPA was still holding strongly to 85 and 5, and in a final fit of compassion stated that

ONE BRIDGE TOO FAR?

It was with mixed emotions that we received the following announcement in our mailbag recently:

Dear Colleague:

On September 4th, during the XV International Congress of Audiology in Krakow, a group of physicians in audiology decided to form an International Association of Audiological Physicians. Participants of the inaugural meeting were Drs. Hinchcliffe, Davies, Martin, Snashall, Stephens (United Kingdom), Bentzen (Denmark), Barr, Liden (Sweden), Jauhainen (Finland), Borkowska-Gaerting (Poland), Prasansuk (Thailand), and Niemeyer (Fed. Rep. Germany); apologized for not coming were Drs. Gannon (Canada), Glorig (USA) and Salomon. Dr. Stephens was elected secretary; Dr. Niemeyer, preliminary chairman was directed to organize the next meeting on the weekend of 1st/2nd November, 1980, in Germany (Marburg or Wiesbaden).

"Thus, after having arranged the priority tasks of organization, I have now the pleasure to invite you to participate in our formation assembly in Wiesbaden from Saturday, November 1st, to Sunday, Nov. 2nd.

The meeting was held to formulate a constitution following the model of already-established national Associations of Physicians in Audiology, e.g., in England, Denmark, etc. Its formation highlights the marked difference between Audiology in the U.S. and Audiology in Europe. Although England has begun to train a specific profession of Audiologists, and other countries such as Israel have followed the U.S. model of Audiology, most European countries have continued to follow a Physician-Audiologist model.

We question whether the attempt to be both Otolaryngologist and Audiologist may not reduce the quality of both performances. The physician-audiologist does not perform the actual day-to-day audiometry and hearing evaluation, leaving that to technicians with little academic training. The use of technicians presupposes a contempt for the skills of audiometric testing — skills which are the life-blood of audiology, without which the profession is emasculated.

We hold basic audiometric testing and interpretation in high esteem, and believe that a high degree of education is requisite to its adequate performance. Why are psychoacoustics, linguistics, psychology, child development, and related academic subjects included in the prerequisites for audiology? It is to establish a basic understanding of the complex interaction between the patient, the tester, and the instrument. It is to develop a confidence that the tester knows more than the machine — that the fundamental element is not the machine but the relationship between tester and subject. It is to recognize that linguistic development must be considered in making any evaluation of auditory function. These and many other considerations make the science of audiology a high art as well as a science. It can only be mastered in day-to-day testing experience, by a knowledgeable, insightful person.

What we are saying is that we like the American model, where the otologist is otologist and the audiologist is audiologist, but where they meet on the common ground of hearing function. To make that meeting ground more effective has been the goal of the American Auditory Society. We like that too.

Letter from England

Dear Editor of Corti's Organ,

This letter could be 'from Scotland' because I have just visited that beautiful historic city, Edinburgh. I had the honour of delivering the Second McBride Lecture entitled 'McBride and the Midfacial Granuloma Syndrome.'

Peter McBride (1854-1946) was the founder of otorhinolaryngology in Edinburgh and his 'department' consisted, in 1883, of one small room only. Dr. Kenneth McLay, one of his present successors, and his colleagues have a large modern department with nearly 100 beds. McBride has been credited with the first description in 1897 of the so-called 'midline granuloma,' an enigmatic (idiopathic) disease of the midfacial tissues. It has stimulated a vast literature and an exercise in terminological acrobatics (a complete list of the terms suggested might exhaust the space allotted to my letter).

Credit is due to another great Scottish otolaryngologist, J.P. Stewart (now 82 and going strong), whose review of the clinical findings of the disease in 1933 has remained a classic. I feel that the eponym I have suggested in 1955: 'Stewart's Granuloma,' is not only well merited but helpful. It was gratifying to find both pathologists and surgeons attending my lecture agreeing with my concept of 'Stewart's type granuloma.'

I have travelled by train to Scotland, an almost forgotten way of travelling, enjoying a renaissance. The train was the

'Aberdonian' and it reminded me of the pride of Scotsmen. When the Titanic sank an Aberdeen newspaper carried the headline — 'Aberdonian lost on high sea!'

I often wished that the big ships still crossed the Atlantic — perhaps we might not be rushing to and from so many symposia.

We have, as you know, attended in September a friendly meeting of the Collegium O.R.L.A.S. in San Francisco under the Presidency of our old friend Frank Sooy, the greatly respected Chancellor of the UC San Francisco. Afterwards we promptly flew to Los Angeles where, at the hospitable Ear Research Institute, a Symposium on Electron microscopy of the Ear has attracted a large and interested audience from all over the world. As always this great Institute provided a congenial atmosphere and their new EM-team under Dr. Frank Galey contributed greatly to the success of the Symposium.

I could only attend the Exhibition of the Academy in Anaheim. There was much 'pathology' of great interest among the exhibited cases.

I wish you and your readers many more happy reunions in your wonderful country and continued success in the New Year.

I. Friedmann

A.G. Bell Assn. Names President Elect

Dr. William E. Castle

Dr. William E. Castle, vice president of RIT and director of NTID, recently was elected the president-elect of the Alexander Graham Bell Association of the Deaf (AGBAD).

Dr. Castle serves as president-elect for two years beginning July 1, 1980, and will become president during AGBAD's 1982 international convention in Toronto. He will serve as president until 1984 and will continue to serve on the board of directors until 1986 as past president.

Dr. Castle has played a leading national role in bringing together the leaders of several major organizations serving deaf people in the United States. In 1979, he brought together the four respective leaders of the National Association of the Deaf (NAD), the International Association of Parents of the Deaf (IAPD), the Oral Deaf Adults Section (ODAS) of AGBAD, and the International Parents Organization (IPO) of AGBAD to discuss issues regarding deafness in the 1980s.

"I hope to see a further coming together of organizations serving the deaf," Dr. Castle says. "Our many organizations need to be able to arrive at an appropriate united front in the interests of deaf people without any one of the organizations losing its own rightful and historical identity."

"During our 1979 meeting, an important point of agreement among the four leaders was that the oral/aural components of 'total communication' must be restored by those who practice it. I'm really convinced that NAD, IAPD, ODAS, and IPO can readily establish a united front on many issues regarding deafness, including early identification, early intervention, the need for better quality education, and optimal implementation of Public Law 94-142 through the maintenance of all legitimate alternatives from which the deaf and their parents may choose."

Dr. Castle served as dean and director of NTID until September 1979, when he was promoted to vice president of RIT, NTID's host institution. He retained his NTID director's position. Dr. Castle also serves as NTID's chief institutional liaison with the executive and legislative branches of the federal government and with national and international constituencies related to deafness.

A native of Watertown, S.D., Dr. Castle obtained his undergraduate degree in 1951 from Northern State Teacher College in Aberdeen, S.D. He later earned a master's degree at the University of Iowa and his doctoral degree in speech pathology and audiology from Stanford University.

Dr. Castle had extensive teaching experience at the college level before coming to NTID in 1968 as assistant to the vice president and as director of NTID's Division of Instructional Affairs. He was named dean of NTID in 1969 and director in 1977.

Glorig Receives Honors

The highest honor of the International Audiology Society was presented to Aram Glorig in Cracow, Poland, in September. Glorig was one of the founders of the I.A.S. and served as Executive Committee member and President of the Society.

The award was given at an impressive ceremony in the State Museum at Cracow. Surrounded by awe-inspiring paintings representing Poland's turbulent history and preceded by a concert by the Cracow Symphony Orchestra, Glorig was given the honor at the hands of his good friend and president of the IAS, Dix Ward. Glorig and Ward were also 1st and 2nd presidents of the AAS.

The IAS biennial meeting was held in the midst of rumblings of Polish protest against the Russians, but the unrest was not felt in the great halls of the meeting. As usual, international friendships were made and renewed without regard for political boundaries. Scientific exchanges were lively, and members felt enriched by the exchanges.

Predoctoral Assistants Wanted

Predoctoral research assistantships are available in the Program in Communication Disorders for highly qualified applicants. Preference will be given to individuals with experience in animal psychophysics, auditory evoked potentials, single unit analysis, neuroanatomy, electrical brain stimulation and computer programming. Send transcript, summary of research interests, GRE and three letters of recommendation. EOAAE.

THE EAR

Injuries to the Ear, and How to Prevent Them

Among the causes of injury to the ear must unfortunately be reckoned bathing. Not that this healthful and important pleasure need, therefore, be in the least discouraged; but it should be wisely regulated. Staying too long in the water certainly tends to produce deafness as well as other evils; and it is a practice against which young persons of both sexes should be carefully on their guard. But independently of this, swimming and floating are attended with a certain danger from the difficulty of preventing the entrance of water into the ear in those positions. Now, no cold fluid should ever enter the ear; cold water is always more or less irritating, and if used for syringing, rapidly produces extreme giddiness. In the case of warm water, its entrance into the ear is less objectionable, but even this is not free from disadvantage. Often the water lodges in the ears and produces an uncomfortable sensation till it is removed; this should always be taken as a sign of danger. That the risk to hearing from unwise bathing is not a fancy is proved by the fact, well known to lovers of dogs, that those animals, if in the habit of jumping or being thrown into the water, so that their heads are covered, frequently become deaf. A knowledge of the danger is a sufficient guard. To be safe it is only necessary to keep the water from entering the ear. If this cannot be accomplished otherwise, the head may be covered. It should be added, however, that wet hair, whether from bathing or washing, may be a cause of deafness, if it be suffered to dry by itself. Whenever wetted, the hair should be wiped till it is fairly dry.

Nor ought the practice of moistening the hair with water, to make it curl, to pass without remonstrance. To leave wet hair about the ears is to run great risk of injuring them. In the washing of children, too, care should be taken that all the little folds of the outer ear are carefully and gently dried with a soft towel. But I come now to what is probably the most frequent way in which the ear is impaired; that is, by the attempt to clean it. It ought to be understood that the passage of the ear does not require cleaning by us. Nature undertakes that task, and, in the healthy state, fulfils it perfectly. Her means for cleansing the ear is the wax. Perhaps the reader has never wondered what becomes of ear-wax. I will tell him. It dries up into thin fine scales, and those peel off, one by one, from the surface of the passage, and fall out imperceptibly, leaving behind them a perfectly clean, smooth surface. In health the passage of the ear is never dirty; but, if we attempt to clean it, we infallibly make it so. Here — by a strange lack of justice, as it would seem, which, however, has, no doubt, a deep justice at the bottom — the best people, those who love cleanliness, suffer most, and good and careful nurses do a mischief negligent ones avoid. Washing the ear out with soap and water is bad; it keeps the wax moist when it ought to become dry and scaly, increases its quantity unduly, and makes it absorb the dust with which the air always abounds. But the most hurtful thing is introducing the corner of the towel, screwed up, and twisting it around. This does more harm to ears than all other mistakes together. It drives down the wax upon the membrane, much more than it gets it out. Let any one who doubts this make a tube like the passage, especially with the curve which it possesses; let him put a thin membrane at one end, smear its inner surface with a substance like the ear-wax, and then try to get it out so by a towel! But this plan does much more mischief than merely pressing down the wax. It irritates the passage, and makes it cast off small flakes of skin, which dry up and become extremely hard, and these also are pressed down upon the membrane. Often it is not only deafness which ensues, but pain and inflammation and then matter is formed which the hard mass prevents from escaping, and the membrane becomes diseased, and worse may follow. The ear should never be cleaned out with the screwed-up corner of a towel. Washing should extend only to the outer surface, as far as the finger can reach. — *The Popular Science Monthly* [From Godey's Lady's Book and Magazine (1873)]

CHABA

(From page 1)

(2) Effects of mechanical force fields (for example, vibration) upon human performance, health, and comfort.

(3) Protection of man from mechanical force fields.

(4) Physical and engineering problems of the generation, measurement and control of mechanical force fields.

As a general policy the Committee will undertake work in the above areas only when the required advisory services are not provided elsewhere.

At present, the Committee is supported by the three armed services and six civilian agencies: The Federal Aviation Administration, the National Aeronautics and Space Administration, the National Institute of Neurological and Communicative Disorders and Stroke, the National Institute for Occupational Safety and Health, the Office of Special Education, and the National Science Foundation. The Committee also cooperates with and gives advice and assistance to four international organizations: the North Atlantic Treaty Organization, the International Civil Aviation Organization, the Organization for Economic Cooperation and Development, and the International Organization for Standardization. These organizations are concerned with establishing standards for transportation noise and providing solutions to auditory problems related to aviation. The Committee is linked with about 40 foreign correspondents through whom an interchange of information in areas of mutual scientific and technological interest is maintained. In addition, the Committee currently maintains correspondence with about 300 scientists.

The Committee gives assistance to its sponsoring agencies in the following ways: (1) applying scientific and technical knowledge to the solution of problems; (2) planning research for meeting future problems; (3) bringing problems that concern supporting agencies to the attention of scientific and technical investigators; (4) promoting exchange of research information; and (5) identifying deficiencies in scientific knowledge and encouraging research designed to reduce them.

The Committee has ten members who have been carefully selected for demonstrated competence and to cover the wide range of specialties pertinent to the work of the Committee. The work requires competence in the biological, behavioral, and social sciences, physics, chemistry, mathematics, engineering, and medicine. Members are selected primarily from universities. Some, however, are selected from governmental, industrial, and private research organizations.

The Committee tries to respond as rapidly as possible to technical questions posed by the supporting agencies. When the Committee has already developed considered opinions or conducted studies on a question, answers can be provided immediately by the Committee's staff. If not, problems may still be handled with small delay through telephone consultations with knowledgeable Committee members. More difficult problems are handled by the Committee through specially appointed small working groups, whose work results in reports. Usually, the Committee has about ten active working groups.

Though a major identifiable product of the committee is the publications that result from Working Group activity, it is well to mention another less visible function of the Committee, namely, its service to those in CHABA's fields of interest. Because CHABA has been active for so many years, and has been relatively visible to those in the fields of hearing, bioacoustics, and biomechanics, it is not uncommon that the office will receive two or three calls daily from scientists around the country requesting information on a given problem, wishing to know who is working on certain problems, wishing to be referred to reports and articles, and asking for information about jobs that are available or submitting information about jobs that are available.

The ten members of the Committee meet twice a year to conduct the business of the Committee. They meet together with the nine representatives of the supporting federal agencies. They consider the problems that are brought to CHABA from the supporting sponsors and decide which would be appropriate for CHABA to work on, which already have answers, and which are inappropriate or should be handled by other organizations. Another function of the Committee is its review and approval of reports generated by Working Groups. In some respects the Committee operates in a manner similar to the board of a journal. They review reports for technical content. Review for major policy issues is considered as well but this concern is shared with members of the Assembly of Behavioral and Social Sciences who also review CHABA reports prior to publication.

CHABA maintains an active correspondence with approximately 200 advisors, about 150 of whom are advisors selected at large from among scientists around the country. They are selected with great care for their research competence and usually have a PhD plus at least five years of high quality publication. There is a group of somewhat less than 100 advisors that are nominated by the sponsors and with whom CHABA also maintains an active correspondence. In many cases, these are scientists who are qualified to be advisors-at-large were they not employed by one of the supporting sponsors. Others, for examples, may be nominated because of administrative interests. Most of the Working Groups are composed of members selected from these groups of advisors but the Committee can go outside its group of advisors to select scientists with special skills that are needed for a particular Working Group.

Abstracts and Summaries from Annual AAS Meeting

(Editors' Note: This and the next issue will contain summaries of the papers that were presented at the annual meeting.)

CARHART MEMORIAL LECTURE

THE INFANT AUDITORY SYSTEM: RE-PROGRAMMED FOR LANGUAGE?

By Marion P. Downs
University of Colorado Health Sciences Center
Denver, Colorado

Marion P. Downs

The new surge of inquiry into language development must assume a high priority with audiologists and otolaryngologists. We have a unique contribution to make to psycholinguistics — one which linguists and psychologists cannot offer — and that is the study of the degree to which the acoustic parameters of language learning in the infant are innate, pre-programmed processes, and how they influence language learning. Already there is research evidence demonstrating that there may be special, biologically predetermined processes of perception for the various acoustical dimensions of speech. It is the purpose of this paper to review what is known about the acoustics of language learning, and to propose contributions that can be made by our disciplines.

How well accepted is the hypothesis that humans are born with a genetic endowment for recognizing and formulating language? It has been proposed that genetic information for language may be coded into our nervous system — that we carry with us special DNA for syntax, special neurons for grammar, special deep structures for coding out the parts of speech. New linguistic theories (1) support a hypothesis that we are programmed to identify words and sentences and generate grammar, as an innate, preadaptive function. This ability evolved through millennia as an evolutionary process exclusive to man. And it developed through the medium of an evolved, articulated speech that impinged on evolved, differentiated hair cells.

For language has lived only through its transmitting mechanism, speech, which is dependent upon our spewing out acoustic energy in various measurable forms. Were it not for this acoustic energy being transformed by our miraculous ears into differentiated, neural patterns, we would still only be able to manipulate visual symbols laboriously and primitively. In lower animals the manipulation of visual symbols with some primitive syntax has been shown to be the limit of language usage. Some have claimed that an elementary, original, grammatic manipulation of visual symbols is proof of "language" in chimpanzees, but it has really no relation to human language.

For speech is the essence — the vehicle upon which language has been carried through eons of time, by all those orbicularis oris opening and shutting billions of mouths, and all those mobile tongues sliding and "ploding" and emitting the acoustic vibrations that became speech.

The vibrations of that speech became intelligible to ears that accordingly developed the most sensitive hearing at those frequencies carrying the specific information-bearing elements of the speech. Or was it the other way around? Did speech develop its specific optimal frequencies at 500-3000 Hz in order to adapt to the ears' most sensitive acuity range? If the ear had been most sensitive at 16,000 Hz would speech have accommodated by evolving its most optimal intelligibility range in the higher areas? Or if speech had arisen in the 16,000 Hz range how loud would it have had to have been in order for the ear to hear? Whichever way it was, evolution has left us with an effective quid-pro-quo.

Lieberman (2) has suggested that "Human speech shapes human language" — that speech and language are interdependent and that the evolution of the one affected that of the other. He shows that an animal is articulate to the degree that it can manufacture a range of formant frequencies corresponding to the vowel triangle a-e-u. Lieberman points out that the anatomical features possessed by man — a well developed pharynx with posterior 1/3 or so of the tongue forming its anterior wall — are optimal for the generation of the wide range of formant frequencies that facilitate speech. No animal other than man has this capacity; hence, man is the animal that has developed speech and its correlate, language.

It is only through what we may call the "mind's ear" that we can transform the acoustic energy generated by the speech mechanism into information, store that information up, and generate theories about life. When we hear some fact that fits a hypothesis our minds literally explode with ideas — neurons scurrying here and there to find other matches for the facts that are being generated. In other words, as Thomas (3) suggests, our minds are actively acting on the incoming material, shaping it, expanding it, giving it new life and form.

Active Auditory Learning

The infants' auditory learning is such a performance — actively influencing the incoming acoustic information as a reflexive activity, pre-programmed to go through this activity to form a basis for what has been called pre-linguistic training. Actually, perhaps there is no such a thing as a pre-linguistic acuity. All auditory acuity related to speech is linguistic, however elementary it may be.

What do we know about the development of auditory perceptions in infants? Most studies in this area point to the fact that the infant uses acoustic information in a reflexive, or innate, manner that lays the matrix for later language development. Perhaps it would be more appropriate to say that it is communication that is innate. For there is evidence that a great deal of non-verbal communication is actively carried out on an instinctive level.

For example, the smile of the infant appears, innately, by two months, as one of the means to attract the parent to him and ensure the infant's survival. The cooing, gurgling sounds that he makes also seduce the parents into loving him. At two weeks he can make these sounds, when the infant larynx has assumed a proper position. The babbling of the human infant up to five months is part of an innate communication activity, evidenced by the fact that a totally deaf infant will babble exactly like a hearing infant for the first five months of life. In these ways the infant acts reflexively upon his social environment in order to influence communication with his caretaker. It has been suggested that the acoustic stimuli that are heard by the developing organism are signals for these self-serving activities to be set off. (18) But when one considers the fact that deaf babies smile, coo and gurgle just as normal babies do, this hypothesis does not seem tenable. The infant needs no acoustic input to initiate the smiling and babbling activities. These activities are part of the innate beginning of communication.

How early does the infant perceive speech and act upon his acoustic environment? There is research evidence for the existence of preadaptive processes of perception for the acoustic dimensions of speech. At birth the infant is able to discriminate its mother's voice and to work to produce her voice in preference to the voice of another female. These capacities were demonstrated by DeCasper and Fifer (4) utilizing the classic sucking paradigm with infants shortly after delivery. Earphones were placed over the ears of the supine infant and a non-nutritive nipple was placed in its mouth. An assistant held the nipple loosely in place; the nipple was connected by way of a pressure transducer to solid state programming and recording equipment that produced only its or its mother's voice. For five randomly selected infants, sucking bursts produced first only the mother's voice on the tape for a predetermined interval, and then the voice of another infant's mother. For another five infants the conditions were reversed. A preference for the maternal voice was indicated if the infant produced it more often than the non-maternal voice. It was apparent that the infant soon learned to gain access to the mother's voice, since specific temporal properties of sucking were required to produce the maternal voice.

These data of DeCasper and Fifer show that newborns reared in group nurseries that allow minimal maternal contact can discriminate between their mothers' and others' speech, and moreover, will work to produce their mothers' voices in preference to those of other females. These authors postulated that prenatal, intrauterine influences may be a factor in this early learning.

Is there sufficient acoustic exposure in the uterus to permit such a precocious development? It may be. Bench (5) has shown that for a 72 dB signal there is the least attenuation of sound going into the uterus at 200 Hz (19 dB); slightly more at 500 Hz (24 dB); more at 1000 Hz (38 dB); and the most at 2000 and 4000 Hz (48 dB). The last two measures were not considered accurate since the strength of the applied signal was not sufficient to overcome the masking of the internal sounds that had been measured at 72 dB. Thus the frequencies of 1000 Hz and below contained the maternal voice may well be heard, if faintly, from the fifth month of gestation when, it has been shown, the fetal ear is capable of analyzing the sound.

The Bench study was not made inside the intact amniotic sac and of course did not deal strictly with the sounds available

to the fetus. But a study by Armitage et al. (6) measured the actual sound level inside the amniotic sac of pregnant ewes by means of hydrophones inside the sac, in the normal fluid environment of the fetus. These investigators found that although sounds from the maternal cardiovascular system were not perceived, the sounds of the mothers' eating, drinking, ruminating, breathing and of their muscular movements, were discernable, as were sounds from outside the mother. They found that the attenuation of sounds measured on a C-weighted scale reached a maximum of 37 dB just below 1000 Hz, but it was reduced below and above this frequency, with its higher frequencies attenuated at about 20 dB up to the highest recorded, 5000 Hz. The amount of attenuation fluctuated however: conversation at normal levels outside the animal could often but not always be understood when transmitted from inside. Raised voices were almost always distinct. If we make the leap from this animal model to the case of the human fetus, then the mother's and even the father's voices would be heard by the fetus. A study similar to the DeCasper and Fifer one, but utilizing the father's voice instead of the mother's would give even more definitive evidence for the fetal hearing of external voices.

Another animal model that is relevant is the study of Gries and Counter (7) who transmitted patterned acoustic signals to chick embryos through the egg shell and found that after birth the chicks clapped their beaks and vocalized more often to the patterned signals than did chicks in a non-exposed control group. The authors postulated that prenatal auditory "imprinting" had occurred.

The above studies lend weight to the hypothesis of DeCasper and Fifer that a great deal of auditory experience has preceded the abilities of the newborn to prefer the mother's voice to other voices. But before such early discriminations can be made the infant auditory system would have to be preadapted to various acoustic discriminations. Such discriminations have been shown to be present in the newborn, and assuming a functional ear and central nervous system the same capabilities would be present in the five month fetus. The innate discriminations that subserve the preference for the mother's voice require the auditory competencies of discriminating rhythm, intonation, frequency variation, stress (supra-segmental aspects of speech) and phonetic components of speech (linguistic aspects).

Supra-Segmental Speech Activity

Condon and Sander (8) reported that neonates move in precise and sustained segments of movements that are synchronous with the articulated structure of speech. Further perception of rhythm in two month old infants was demonstrated by Demany et al. (9) who utilized varied sequences of time bursts in a habituation paradigm relating duration of fixation on a visual figure. Infants were able to perceive intervals of time as subjective links between sounds. Spring and Dale (10) showed that one to four month old babies could discriminate linguistic stress as well as location, fundamental frequency, intensity, and duration. Thus the entire gamut of supra-segmental aspects of speech seem to be available to the infant at birth.

Kimura (11) has shown that the supra-segmental aspects of speech are handled by the right brain. The segmental, linguistic aspects are located in the left brain, according to Studdert-Kennedy and Shankweiler (12). But this is not to deny the importance of the supra-segmental aspects of speech in learning its intelligibility. Language learning is not confined to the segmental aspects of speech. Rhythm, intonation, duration and stress are extremely important to understanding multiple meanings of words, as well as to the meanings of homophones. Many words and phrases contain multiple meanings that are made clear only by intonation, rhythm, duration and stress. This fact explains a part of the problem of a deaf child in understanding some of the subtle parameters of irony, satire, scorn, implied anger, or humor, that convey the sense of multi-meaning words or phrases. "You're tired," "You're tired?" are two different sentences depending on the intonation of the rising or falling fundamental frequency. "You drive me up the wall," "I can't bear it" — make for humorous misconceptions, but it is the kind of thing that is difficult for the concrete-minded deaf child who has not heard the stress and intonations that make the phrases meaningful.

Franklin (12) showed that there is useful consonant information in the low frequencies. Rosenthal (13) also showed that when a low frequency band is added to a 1100-2200 Hz high band, there is a significant increase in consonant recognition. So, to return to the pre-natal learning that may go on, whether the fetus hears low frequency sounds better than high or not may not matter to the early learning that goes on.

Segmental Aspect

Eimas (18) and others have given us evidence that the child is also able to discriminate segmental aspects of speech in a categorical and presumably linguistic manner. He chose to utilize differences in voice onset time (VOT). The categorical perception of VOT has been assumed to be a function of the special processing which the sounds of speech undergo and tends to be a special characteristic of perception in a speech or linguistic mode. Eimas (18) believed that there were special biologically determined processes of perception for this acoustic dimension. In one experiment with 26 infants one month old, he employed the classic sucking paradigm in discriminating the differences between the voiced stop /b/ and the voice-

(Cont. on page 10)

Minutes of the Executive Committee of the American Auditory Society

DATE: November 20, 1980

PLACE: Henry Ford Hospital
Detroit, Michigan

TIME: 12:30 p.m.

Members present: Marion Downs, Bruce Graham, Earl Harford, Suzanne Kos, Ed Johnson, Ross Roeser, Hiroshi Shimizu, Laura Wilber

Members absent: Charlie Anderson, Susan Conway-Fithian, Malcolm Graham, Merle Lawrence, Fred Linthicum, Samuel Lybarger, Ralph Naunton, John Sinclair, Dixon Ward

1. President Wilber opened the meeting at 12:30 p.m.
2. The minutes from the 1979 Executive Committee meeting held in Dallas, Texas, were presented and approved without revision.
3. The income and disbursements for the period January 1, 1980, through August 31, 1980, were reviewed, discussed and approved.
4. A list of 182 applicants for membership during 1979 was presented. Of this number 144 were approved for membership, 37 had incomplete applications as they did not have the necessary signatures, and 1 was disapproved for membership due to lack of the minimum educational and experience requirements.
5. The results of the ballot to amend the AAS bylaws were presented. Three hundred sixteen votes approved the adoption of both the associate membership and liquidation amendments. Two voted to adopt only the associate member-

ship amendment, 60 voted to adopt only the liquidation amendment, and 5 voted no change. The final result was that both the amendments were adopted.

6. A discussion was held regarding consideration of a dues increase for 1982. Although it was realized that increased costs will eventually cause an increase in dues, after the discussion it was decided that dues not be increased for 1982.

7. The 1981 meeting will take place in New Orleans, Louisiana, in conjunction with the American Academy of Otolaryngology.

8. The program chairman for the 1981 meeting will be Dr. Michael Seidemann.

9. A discussion was held regarding future meeting sites. Following the discussion a motion was made and approved that AAS meet alternately with the American Speech-Language Hearing Association and the American Academy of Otolaryngology.

10. President Naunton was appointed the chairman of the 1981 Carhart Memorial lectureship award. He is charged with generating the list of candidates for the award. After the candidates are identified, each member of the Executive Committee will vote on the candidates. It was recommended that the list of the previous committee (chaired by Lybarger) be shared with him.

11. Ross J. Roeser was appointed secretary/treasurer for 1982.

12. Suzanne Kos was appointed assistant secretary/treasurer for 1982.

13. Charlie D. Anderson was appointed Vice President/President Elect for 1981.

14. It was agreed that American Auditory Society would forward the name of Dr. Howard House as a candidate for the CRS Amplifon Award.

15. Dr. Harford brought up the possibility of publishing a separate membership directory. After discussion it was decided that the secretary/treasurer would explore the costs of offset printing for such a directory. In addition, the future directories should be published in *Corti's Organ* in a clip-out format.

16. Drs. Shimizu and Johnson were appointed as the nominating committee for 1981 elections for the Executive Committee. Those members whose terms expire in 1981 are: Bruce Graham, Earl Harford, Suzanne Kos, Merle Lawrence, Fred Linthicum, Samuel Lybarger, and Dixon Ward.

In order to continue to maintain a balance of interests on the Executive Committee, 4 audiologists, 2 otolaryngologists, and 1 individual representing the hearing aid industry must be nominated for election.

17. A discussion was held on the status of Ear and Hearing, and the following points were resolved:

A) \$1,000.00 would be transferred from the American Auditory Society account to the Ear and Hearing account.

B) Annual awards will be given for outstanding papers published in the journal. These would consist of a first place award of \$300.00, second place award of \$100.00, and honorable mentions having no cash awards. These awards will be initiated for volume 2 (1981), and would be presented at the 1982 annual meeting. The editorial board would nominate articles for first and second prizes and for honorable mentions. These nominations would be reviewed and approved by the Executive Committee.

18. After discussion a motion was made that members should be prohibited from using the name of the society in personal advertising. This motion passed. Earl Harford and Marion Downs were appointed by President Wilber to provide guidelines on this matter.

There being no other business, the meeting adjourned at 2:05 p.m.

Decibel (From p.1)

"a time weighed average exposure level of 80 dBA with a 3 dB trading factor is necessary to assure that no employee will suffer material hearing impairment over his working lifetime" (7).

In October 1975, just to keep everyone on their toes, EPA identified 80 dBA as safe, but makes no recommendation to OSHA; and then continues, "in order to take into account the fact that susceptibility to noise-induced hearing impairment varies widely among the population, OSHA must select a maximum permissible exposure level adequately protective on a basis of at least the 90th percentile" (7).

Further — into October and from "Noise Report" (9)

Pressure is building to permit continued use of hearing protectors, yet consumers union evaluated thirty-two types and concluded none of the tested devices can offer absolute protection.

And finally another intriguing note,

OSHA figures that medium-sized business (between 100 and 249 employees) are most often cited for noise violations (10).

Nineteen seventy-six was now upon us and still no final draft. A favorite tune of the noisy new year was "may 90 dB not be forgot and days of ear protection." And sure enough, they were not! More hearings, more reports, more "damnation" between the groups involved.

The "Inter-Industry Noise Study" that was heralded as the true revealer of cause and effect was going ahead full steam, and promised final factual information on the effect of noise on workers. Environmental groups, labor organizations, insurance companies, EPA and OSHA officers, and the American Speech and Hearing Association issued statements bi-weekly. Industry and management counteracted with vigor. But still no final draft, although public hearings had ended.

December of 1976 was distinguished by a memorandum prepared by Leon Billings, staff director of the Senate Public Works Subcommittee on Environmental Pollution, on scheduling environmental legislation for 1977 which indicated that three days of on-site hearings on implementation of the Act (Noise Control Act of 1972) will probably be conducted during 1977 in preparation for amendments in 1978 (11). Therefore, 1977 looked like "more of the same."

Sure enough, New Year announcements clearly indicated that our poor decibel was still in a battle. Dr. Morton Corn, still Assistant Secretary of Labor for OSHA, told Dr. Raymond Yerg, Chairman of the Inter-Industry Noise Study Steering Committee (IINS), that he did not plan to hold a post-hearing comment period open specifically for the purpose of receiving the results of the IINS's study, but would put it on his schedule of a final noise standard in February 1977. He (further) noted

that revisions to the occupational noise rule had been in the works since 1972, and that further delay was "unthinkable" (12). He then turned in his resignation.

OSHA quietly followed Dr. Corn's resignation with the news that it was reopening the docket for limited comment on additional data on the economic impact statement that was prepared by Bolt, Beranett and Newman Inc. and that limited comments would be accepted until February 28th (13). This announcement was followed by a notice that IINS intended to use the reopened docket to submit results of its three-year research project on the effects of continuous exposure to workplace noise.

The rest of 1977 passed with noticeable "quietness." As a matter of fact little noise was heard from 1977 through 1979 except from the Research Report of the long-awaited Inter-Industry Noise Study that was published on May 7, 1978 (21); the field investigation of noise reduction afforded by insert-type hearing protectors in November 1978 (1); and finally the 1979 mandatory requirement of standardized reporting of "Hearing Protector Noise Reduction" by manufacturers (14).

The year 1980 brought the battle of the decibel back (if you will excuse the expression) with a bang. The April 18th Federal Register (15) contained the explosive news that

Occupational Safety and Health Administration (has) reopened its rulemaking record on its proposed revision to the occupational noise standard in order to include material that has been submitted to the agency since 1977, when the record was closed, and to introduce some undated cost information on the proposed revisions. OSHA will also be accepting written comments on the new material for inclusion in the record.

It was a hot summer to be sure. In July various industrial groups and individuals including such giants as Owens-Illinois Inc., Fiber Box Association, and American Paper Institute issued a statement on personal hearing protection that asked for it to be "elevated to the same status as engineering and administrative control" (16). Further, that

For OSHA to ignore the importance of hearing conservation programs in its regulatory process is a serious deficiency. API believes that OSHA should carefully consider its previous testimony on the priority of hearing conservation programs (16).

Fall 1980 — the battle has yet to end and the poor decibel struggles on. Why does the battle rage? Primarily because of what we do and do not know. Let's start with what we do know; knowledge that provides armament for the battle.

One of the biggest arguments against lowering the acceptable noise level is that the employee can be adequately protected from the effects of noise exposure by the simple use of EAR PROTECTORS. Further, everyone knows they do not cost much. A good argument; however, "it ain't necessarily so."

We who have evaluated the effectiveness of ear protectors are fully aware of the fact that there is a substantial difference

in the amount of protection one type of ear plug, and even ear muff, will provide one individual over another. Our own research shows a maximum difference of 40 dB between individuals using the same make of ear plug; and in one case, it increased hearing acuity at certain frequencies. Contributing factors to this variance included size of ear, shape of ears, difference between one individual's two ears, and shape of head when ear muffs were utilized.

Until 1979 there were no national standards for ear protectors. It took until September 12, 1979, for the Federal Environmental Protection Agency to issue a final rule that would require manufacturers to place labels on every hearing protector. In addition, one year from the issue of the standard all manufacturers "will be required to test all categories of protectors offered for sale according to the procedures specified by the American Standards Institute" (14). Unfortunately — or typically — EPA started granting "Relief" on hearing protector labels by February 1980 (17).

The most important study that dealt with the complexity of ear protector use was the Field Investigation of Noise Reduction afforded by insert-type hearing protectors, published in November 1978 (1). We herein quote from the abstract:

Results indicate that, on the average, workers were receiving noise protection ranging from a minimum of about 6 dB at 125Hz to a maximum of approximately 20 dB at 3150Hz. (Test frequency range was 125 to 8000Hz.) Comparison of these results to corresponding data established in the laboratory, and reported by the earplug manufacturers, shows that half of the workers tested were receiving less than 1/3 of the potential attenuation of the hearing protectors in terms of noise reduction in dBA. Additional special testing demonstrated that this reduced performance probably was due to the workers using the wrong size for their ear canals and/or improperly inserting the earplugs. The degree of protection was not found to depend significantly upon intensity of workplace noise level, earplug design or company policy regarding earplug usage; however, a significant difference was found between the attenuation received in the first test of all workers and in the four subsequent tests. A slight difference was also demonstrated between workers having an "active" job task compared to those with a more "passive" job activity.

The enforcement of protector use has also caused considerable concern. This is typified by the following "Standard" issued by OSHRC in July of 1980 (18).

WEARING OF HEARING PROTECTION IS "IMPOSSIBLE TO ENFORCE," OSHRC SAYS. An employer should not be cited or fined for the failure of one employee to wear hearing protection, Occupational Safety and Health Review Commis-

(Continued on p. 11)

Hearing Aid Workshop

SECOND ANNUAL HEARING AID PRESCRIPTION WORKSHOP

New Directions and Practical Applications to Hearing Aid Selection and Fittings

Objective: To present an intensive one-day learning program designed to improve the effectiveness of your hearing aid fittings. State of the art techniques to insure better client satisfaction in less time. Scenario for success in the 1980s.

Some of the urgent questions to be addressed:

- Are our present hearing aid selection procedures adequate for the 1980s?
- Are we ignoring state of the art research that could significantly benefit our hearing impaired clients?
- Is the speech test based approach sensitive enough to choose the most appropriate amplifier? If not, what are the alternatives?
- Is there an ideal frequency response with wide application for many of the hearing impaired?
- Is the 2 cc coupler appropriate for our needs?
- How important is sound quality in hearing aid selection?
- Why the Killion technology is vital in achieving client satisfaction.
- Is it time to assume binaural superiority for most bilateral impaired clients?
- Are our sound field measurements accurate and valid?

Time: Saturday, April 11, 1981, 8:45 a.m. to 4:30 p.m.

Place: Franklin Plaza Hotel, Philadelphia, Pa.

Fee: \$95.00 including lunch and all workshop materials.
\$75.00 student fee

Enrollment limited

Address communications to:

The Unnatural Laws of Academe

THE GOLDEN RULE OF ARTS AND SCIENCES
Whoever has the gold makes the rules.

BOREN'S FIRST LAW
When in doubt, mumble.

BARTH'S DISTINCTION
There are two types of people: those who divide people into two types, and those who don't.

SEGAL'S LAW
A man with one watch knows what time it is. A man with two watches is never sure.

NINETY-NINETY RULE OF PROJECT SCHEDULES
The first 90% of the task takes 90% of the time, and the last 10% takes the other 90%.

HOWE'S LAW
Every man has a scheme that will not work.

SKINNER'S CONSTANT (FLANNAGAN'S FINAGLING FACTOR)
That quantity which, when multiplied by, divided by, added to, or subtracted from the answer you get, gives you the answer you should have gotten.

CHABA (from p.3)

HISTORY OF CHABA

CHABA was constituted in 1956 as the Committee on Hearing and Bioacoustics and operated out of a secretariat at the Central Institute for the Deaf at St. Louis, MO. At this time it was funded by the Army, Navy, and Air Force. However, it has its roots in a Committee on Hearing that had functioned from 1943 until 1952. Interestingly the Committee on Vision had a similar early beginning in World War II as the Vision Committee. Then, later, was reformed as the Committee on Vision and was operated by a secretariat at the University of California and later at the University of Florida. In 1959 the Committees were combined and the secretariat was brought to Washington to function here with the National Research Council. This permitted a full-time professional who divided responsibilities between the two committees. Later, as the activities of the two committees continued to grow, it became necessary to add a second professional, one responsible primarily for the Committee on Vision, and the other for the Committee on Hearing, Bioacoustics and Biomechanics.

Recently CHABA has changed its interests. In the audiometric area, for example, CHABA has shifted somewhat from military problems dealing with the measurement and care of the hearing of healthy young males, for whom a certain amount of hearing risk is often permitted because of operational necessity, to a concern with protecting the hearing of the public at large from any audiometric loss at all. This change has, in part, resulted from the sponsorship of CHABA having changed from being purely military to include federal agencies that are concerned with health. CHABA has also become more concerned with noise produced by aircraft and the control of such noise sources because of the addition of sponsorship from the Federal Aviation Administration and the National Aeronautics and Space Administration. A third change in CHABA's interest areas has come about because of the inclusion of biomechanics. This has encouraged activity in areas such as O and multiple G, tolerance to vibration, impact injury (both head and whole-body impact), acceleration, spin and rotation.

If one categorizes CHABA activity during the past years into areas such as audiometry and hearing conservation, airport noise and attitude surveys, relation of hearing loss to noise exposure, biomechanics, speech perception, non-auditory effects of noise exposure, and finally, noise control (either through quieting of the source or through ear protection), a few trends may be noticed which are of interest. First, the activity of CHABA in the area of noise control has decreased. This is unfortunate because the engineering control of noise holds forth perhaps more promise for ultimate alleviation of noise as a pollutant or hazard than almost any of the other areas in which CHABA might participate. It might be well to consider entering this area again. Secondly, the activity in audiometry and hearing conservation, airport noise surveys and the relationship of hearing loss to noise exposure has maintained almost a constant level neither increasing nor decreasing. It might, however, be interesting to note that the level of activity within CHABA for audiometry and hearing has always been double the activity in any of the other general categories. Thirdly, the CHABA activity level for biomechanics, speech perception, and non-auditory effects of noise has increased during the past few years.

If for no other reason, simply because of its long life of some thirty years, CHABA has an excellent image nationally. Its reports are referred to repeatedly in open journal publications. Many of its reports have been adopted by the American Standards Association and now the American National Standards Institute, without modification, as national standards. The Committee is almost as well known internationally as it is nationally, since many of the journals published in this country are read by researchers in other countries. CHABA's International Correspondents also contribute to this image in that they are recipients of all of the reports of CHABA and thus tend to disseminate throughout many of the countries of Europe information that has been published by CHABA. In fact, at meetings of the International Standards Organization the U.S. delegates on acoustical committees are often asked by foreign delegates about CHABA's posture on an issue.

STATUS OF CURRENT PROJECTS

Working Group 61 — Hearing Retirement Standards for Speech Testing in Noise

This Working Group is to develop a test of speech reception in noise. This test should be suitable as a partial determinant of whether military personnel should be retained on duty or retired with compensation for their hearing impairment. The Working Group supervised the development of a set of speech materials in noise at various speech-to-noise ratios and has administered that test both to normal and hearing impaired populations of varying ages. This test also has been interrelated with a battery of other selected speech reception tests and, of course, pure tone audiometry. These data have been combined into a final report which is presently under revision. It is estimated that this report will go into review by ABASS in October 1980.

Working Group 73 — A National Standard Fire Alarm

This group was to recommend the most desirable two or three audible signals that are maximally detectable, relative to other audible signals, when presented indoors where large numbers of people are gathered (apartments, hotels, motels, schools, hospitals, stores, factories and offices) for consideration as a national standard fire alarm. This Working Group met only once and agreed to the most desirable audible alarm signal for use as a national standard fire alarm. Its report was

published in the Journal of the Acoustical Society of America in 1975. The reason the group is still in existence is to monitor the efforts of an American National Standards Institute (ANSI) Working Group and an International Standards Organization (ISO) Working Group, both of whom are attempting to develop a national standard fire alarm and an international standard fire alarm, respectively. These two Working Groups are in close cooperation. The Study Director of CHABA is serving on the national group as an advisor and is the chairman of the international group. It might be of interest to note that the international group met in June 1980 in New York City and voted unanimously to adopt the CHABA signal. There is no reason to believe that the ANSI group will not follow suit. Currently, member nations of ISO are checking to see if any organizations within each of the nations might be opposed to the CHABA signal. This survey will be concluded by December 31, 1980. It is possible that the CHABA signal, as reported in 1975, will become an international standard in 1981.

Working Group 81 — The Effects of Long-term Exposure to Noise upon Human Health

This Working Group was asked to conduct a critical review of the literature in this area particularly emphasizing the recent literature that has accumulated since CHABA published its report on this topic in 1971. The report has been drafted, approved by the Working Group, approved by CHABA, and is now being reviewed by ABASS.

Working Group 83 — The Effects of Intermittent Noise on Speech Intelligibility Indoors

This Working Group was asked to review the literature concerning the effects of intermittent noise on speech intelligibility indoors. Recommendations are to be generated concerning minimal sign-to-noise ratios below which communication is disrupted. Additional guidance may be given concerning sound treatment. The Working Group has prepared and approved its final report, it has been approved by CHABA, and with the exception of a few minor corrections that will be dealt with on a conference telephone call scheduled for September 3rd, the manuscript should be available for review by ABASS by September 10, 1980.

Working Group 84 — Human Response to Impulse Noise

This group was asked to consider the human response, particularly of annoyance and sleep interference, to impulse noises ranging from 90 to 140 dB peak pressure with pulse durations ranging from 40 to 1000 milliseconds. The literature is to be reviewed and criteria are to be suggested, below which annoyance and sleep interference will not present a problem to the public. The Working Group has been asked by the Environmental Protection Agency to await a table being developed by the agency which might be appropriate for inclusion in the final report of the Working Group. Following that, the group is ready to draft the final report and it should be available for review by CHABA about November 1980.

Working Group 85 — The Effects of Noise Exposure on the Human Fetus

The Working Group was asked to assess the potential hazard to the human fetus resulting from noise exposure of pregnant women and to propose limiting noise exposure conditions, as well as to recommend specific research efforts that might resolve unanswered questions. The final report of this Working Group is being drafted by Dr. William Neff and should be available for Working Group approval in October 1980, following which it will be submitted for approval by CHABA and eventually by ABASS.

Working Group 87 — Feasibility of a National Biomechanics Data Bank

This Working Group was asked to examine the feasibility of collecting biomechanical data originating from various technical programs, conducted or sponsored by various federal agencies and private sources, into one integrated data bank. The Working Group has completed its final report and approved it. CHABA has approved the report and it is now being reviewed by ABASS.

Two reports were published during the past year:
The Effects of Whole-Body Vibration on Health. Working Group 79. Henning E. Von Gierke, Chairman, March 1979.

The Multiple Position Letter Sorting Machine: An Evaluation of Visual, Auditory, and Human Factor Problems. Working Group 88. J.W. Gebhard, Chairman. 1979.

Six reports are in the final stages of editing.

FUTURE PLANS

A proposed Working Group, number 89, on Tinnitus is being submitted to ABASS for approval at the next meeting. The group will be asked to review and evaluate critically the existing literature on tinnitus. Topics to be included are (1) experimental and clinical reports concerning the causes of tinnitus, (2) the advantages and disadvantages of the various procedures for measuring tinnitus, and (3) the relative efficacy of current techniques for treating tinnitus (including biofeedback, drug therapy, surgery, and direct electrical stimulation). Pertaining to tinnitus maskers specifically, the Working Group will try to evaluate (4) their reported long- and short-term effectiveness, (5) the potential hazards associated with their prolonged use (e.g., additional hearing loss), and (6) whether there are at present sufficient experimental and clinical data to permit issuance of specifications for optimal acous-

(Continued on p.10)

Audiology Update

A new series of continuing education programs, "Audiology Update," got off to a successful start in 1980, and plans are well under way for the 1981 program.

Sponsors of the Audiology Update series are SUNY Upstate Medical Center in Syracuse, N.Y., and the University of Nebraska Medical Center in Omaha. Program directors are Alan Feldman, Ph.D., professor of otolaryngology and communication sciences at SUNY, and T. Wellington Norris, Ph.D., professor and director of the Division of Audiology and Speech Pathology at Nebraska.

The 1980 program, held in Itasca, IL, focused on hearing aid dispensing, with emphasis on practical aspects, and on language and language processing. A review of language as a tool in audiologic evaluation of impairment in auditory processing was supplemented by an overview of the status of auditory evoked potentials in the evaluation of the central auditory system.

Faculty, in addition to Feldman and Norris, were Robyn Cox, Ph.D., Memphis State University; Julia Davis, Ph.D., University of Iowa; David Goldstein, Ph.D., Purdue University; C. Thomas Grimes, Ph.D., SUNY Upstate Medical Center; Stephen D. Kasden, M.S., Providence, R.I.; George Lynn, Ph.D., Wayne State University; Jane Madell, Ph.D., New York League for the Hard of Hearing; Lynne Marshall, Ph.D., University of Nebraska Medical Center; Norma Rees, Ph.D., City University of New York; Paul Skinner, Ph.D., University of Arizona; and Jack Willeford, Ph.D., Colorado State University.

The 1981 Audiology Update will be held June 24-27 at the Viking Motor Hotel and Newport Convention Center, Newport, RI. Topic of this program is "Protocol for Audiologic Diagnostic in the '80s."

Sessions will cover idiopathic hearing loss, evaluation and management of tinnitus, audiologic evaluation of middle ear function, ENG as an audiology service, brainstem audiometry, and evaluation of sensorineural hearing loss. Practicums will be offered on acoustic immittance and interpretation of ENG records.

Faculty will include Robert G. Turner, Ph.D., James F. Jerger, Ph.D., Robert H. Margolis, Ph.D., Stephen D. Kasden, M.S., Robert J. Ruben, M.D., Alan S. Feldman, Ph.D., C. Thomas Grimes, Ph.D., Charles Parkins, M.D., Lytt Gardner, M.D., T. Wellington Norris, Ph.D., and Lynne Marshall, Ph.D.

Special Amplification for the Mentally Retarded: A Helmet-Mounted Hearing Aid

David A. Klodd, Leslie J. Block,
Jeff Higenbotham, and Terry Griffing.

ABSTRACT:

Diagnosing hearing loss and providing appropriate amplification for the mentally retarded is a problem encountered by audiologists. Amplification has generally been considered impractical for those individuals with self-abusive behavior. The paper gave a case report of the utilization of brainstem auditory evoked potentials for the diagnosis of hearing loss, and the development of a helmet-mounted hearing aid. Findings revealed an increased awareness to sound by the child and a reduction of his self-abusive behavior.

Children's Speech Discrimination in Noise

BRIAN M. SHAW and HOWARD M. GUTNICK
BOWLING GREEN STATE UNIVERSITY
BOWLING GREEN, OHIO 43403

Tests of speech discrimination, in a background of noise, have been investigated extensively in adults. Some recent investigations have shown that children who have learning or reading problems may show poor figure-ground ability. For example, one study showed that many learning-disabled children required better signal-to-noise ratios to achieve a speech reception threshold than did normal-hearing children.

Although normal children who are older than 6½ years have discrimination scores in quiet equal to those of adults, a significant difference may become apparent when the speech is combined with ipsilateral noise. Data for discrimination in noise of normal children using the CID W-22 word lists are not available. The purpose of this study, then, was to fill that gap.

The children were selected from an elementary school located in Bowling Green, Ohio. Ten children were selected from each of three age groups, 7, 9, and 11 years. Each child was within six months of his or her yearly age. Five of the children from each age group were boys and five were girls. All of the children had negative histories of hearing loss or middle-

ear problems as determined by a questionnaire sent home to the parents. When doubts arose, the parents were called to obtain more detailed information. Each child had thresholds which were at most 10 dB Hearing Level from 500 to 4000 Hz, type A tympanograms, and a crossed acoustic-reflex response to a 1000 Hz tone at 100 dB Hearing Level. All of the children passed the Goldman-Fristoe Test of Articulation.

The testing was done in a quiet room within the school, the same room in which the hearing screening was completed. An Auditec of St. Louis cassette tape recording of the CID W-22 word lists was used. The recorded lists were mixed with white noise that was generated by a Grason Stadler Model 162 speech audiometer and then fed to a TDH-39 earphone. The word lists were presented at 70 dB sound pressure level and the noise was varied accordingly to obtain signal-to-noise ratios of -9, 0, +9, and +18 dB. The order of presentation of the experimental conditions was randomized. The children were asked to repeat each word, even if they had to guess. Before testing, each child listened to 10 words, at a signal-to-noise ratio of +20 dB, in order to familiarize them with the task.

The data were analyzed statistically with a three-way repeated-measured analysis of variance. In order to make the variance homogeneous, the proportional scores were submitted to an arcsin transformation, and the ANOVA was done on the transformed scores.

The performances in percent correct of the 7, 9, and 11 year old boys and girls are plotted here as a function of signal-to-noise ratio. Please note that although the statistical analyses were done on arcsin-transformed data, we will present our graphs and tables in terms of percent correct, a more familiar and tractable unit. Several results are noteworthy. There were no significant differences due to the children's age. That is, the older children did not do better than the younger children as we had expected. Possibly for this task, the children's ability has matured by 7 years of age. In addition, the test may not have probed the children's semantic-closure skills, which have been linked to language skills and therefore expected to display maturational trends.

Oddly enough, we did note a significant main effect due to sex. The boys did better at each signal-to-noise ratio by about 4 percent. Although this was a statistically significant difference, we concluded that the difference was too small to be considered clinically relevant.

This is the growth function of the means and standard deviation, collapsed across age and sex. The function rises monotonically with a slope of 2.63 percent per dB. The 50

percent point of discrimination is at a signal-to-noise ratio of 7 dB, an interpolated value.

The data you saw on the previous slide are presented here in tabular form. The mean scores of 6 percent at -9 dB and 22 percent at 0 dB imply that the task was very difficult at these signal-to-noise ratios, and therefore, probably not of clinical value. The mean scores of 58 percent at +9 dB and 78 percent at +18 dB appear to be more appropriate in that they allow the child to perform well enough to stay interested. We recommend that clinicians select signal-to-noise ratios greater than +9 dB for this task.

In line with this, expected scores at other often-used signal-to-noise ratios are presented in this table. These are interpolated or extrapolated values. Therefore, at +10 dB, we could expect a performance of approximately 62 percent; at 15 dB, 72 percent, and at 20 dB, 82 percent.

Thorton and Raffin, in 1978, proposed that the performance of open-response tests of speech discrimination can be modeled as a binomial variable. Although their model was devised to estimate an individual's true score from one equivalent list to another under different conditions, the model may be useful in this application. If the mean scores we measured are assumed to reflect the expected scores of normal-hearing children, then the model can be used to predict if a score measured on a client is significantly different than the score expected of normal-hearing children. For example, the overall mean performance was 58 percent at a signal-to-noise ratio of 9 dB. According to the model, the 95 percent confidence interval of the true score is from 40 to 76 percent. Therefore, one can say that a child who scores less than 40 percent for this condition has performed significantly below his or her peers. Of course, additional data using this test must be collected on children with learning disabilities, central auditory dysfunction or peripheral hearing loss in order to determine if their performance is significantly poorer than normal-hearing children and if that difference is clinically meaningful.

In summary, this study provides an articulation function of the Auditec of St. Louis version of the CID W-22 word lists in a background of white noise at various signal-to-noise ratios for normal-hearing children. The scores we obtained can be used as norms to compare the performance of children with learning or reading disabilities, central auditory dysfunction, or peripheral hearing loss. Until additional research is done, it is suggested that an extension of a binomial model, as used by Thorton and Raffin, in conjunction with the norms provided, can aid the clinician in making valid clinical judgments.

Infant Auditory System (cont.)

less stop /p/ combined with the vowel (a). His results indicated that infants as young as 1 month of age are not only responsive to speech and able to make rather fine discriminations but that they are capable of perceiving voicing distinctions in a manner approximating categorical perceptions.

Later studies by Morse (14) confirmed the fact that infants as young as two months were able to process or perceive distinctions in a linguistically relevant manner, showing that categorical perception is present in infants before the onset of speech production. Morse investigated 2 month old infants' abilities to differentiate the voiced stops (b) and (g) in a speech context from the same second and third-formant transitions in a non-speech context. (The non-speech context was achieved by eliminating the entire first formant and the steady-state portions of the second and third formants.) Using the sucking paradigm he demonstrated that the experimental infants discriminated the speech sounds by increased sucking. They also recovered differentially from the control group who had heard the synthetic patterns. This, he felt, confirmed the linguistic relevance of their distinctions.

The theoretical considerations of the infant's ability to process a segmental unit of speech have occasioned a great deal of speculation. The arguments revolve around the fact that speech is a very complex code; transformation of the acoustic energy signaling speech to the perceptual event may not be a simple conversion mediated by an auditory decoder. Lieberman (2) states "The acoustic cues for successive phonemes are intermixed in the sound stream to such an extent that definable segments of sound do not correspond to segments at the phoneme level. Moreover, the same phoneme is most commonly represented in different phonemic environments by sounds that are vastly different. There is, in short, a marked lack of correspondence between sound and perceived phoneme. This is a central fact of speech perception." Lieberman believes that the perception of speech signals is mediated in some manner by central neural events, because infants have had no experience in the consistent articulation of phonetic distinctions. Therefore the ability must be a part of the native endowment of the human organism.

Other theories have been advanced by Stevens and Hale (16) and Stevens and House, (17) who presented an analysis-by-synthesis model presupposing that an internalized or computed auditory pattern is generated and compared with the stored pattern. But for this theory also the premise is that "perception requires knowledge of phonological rules that can map abstract features into articulatory events" (Eimas). So all theories lead to the inescapable conclusion that the infant enters this world with considerable knowledge of the phonological component of language.

Eimas points out that when one compares the degree of categorical perception of the VOT in infants with that of adults the degree does not appear to be age-related and therefore is unaffected by experience with language of either a perceptual or a productive nature. Eimas explains the infant's ability to differentially discriminate VOT differences by assuming these detectors are operative shortly after birth, and may be made functional by merely experiencing speech.

Whether the infants' detectors are activated shortly after birth as Eimas has suggested or whether they have become functional during inter-uterine life may be a relevant question to his theory. Four months of listening practice might facilitate in a way the categorical perceptions that are evident at birth. However, we suspect that if the same kinds of experiments could be made on the unborn fetus at five or six months gestational age categorical perception would be present and would demonstrate that detectors need only be activated by hearing speech in order to be fully functional. It remains for some zealous researcher to attempt to replicate these studies during inter-uterine life.

The fact that the infant is able to discriminate the acoustic features of speech means that he can segment an almost continuous acoustic input into discrete elements. This ability to process language into discrete elements is a basis for full language competence. The infant's ability to do this at the very beginning of language acquisition means that he does not have to learn that language is formed by discrete elements. The result is a facilitation of the language acquisition process and indeed the ability to break down discrete elementary language may even be requisite to its formation. The audiologist should note that the capacity to process language in discrete units would not be possible were it not for the damping effect of the structures of the cochlea. Were speech sounds — and indeed, any sounds — allowed to reverberate without hindrance in the ear the hair cells would not be able to discriminate the discrete frequency components of the speech sounds in a manner necessary to language perception.

Reflexive Rehearsal Activities

There appear to be a number of rehearsal activities that the infant is programmed to carry out. Meltzoff and Moore, (19) and Reddy and Rao (20) have described both manual and facial imitations in newborn infants — abilities which disappear shortly and reappear again at about a year of age. These researchers show such imitative movements as pursing the lips, opening the mouth, and even sticking out the tongue — all of which seem to be precursors of later speech and articulatory movements. The infant seems to be going through these imitative movements as a kind of rehearsal for later more consciously controlled speech activities.

Bower reviewed a number of early skills that are retrieved when they are required by the infant at a later time. He hypothesized that the reason that sensori-motor abilities disappear is that they are not exercised. He tested this hypothesis by

administering a selection of various tasks to infants only days or weeks old and gave them intensive practice in performing the tasks as soon as their abilities appeared. However, he found for example that the practice of ear-hand coordination in what he called Phase 1 actually accelerated the disappearance of the coordination and retarded its reappearance in Phase 2 (around a year old).

Bower attempted to explain this phenomenon in terms either of lack of motivation of the infant, or of the passivity of the auditory system. He maintained that although the infant can turn off its visual system by closing its eyes, it cannot turn off its auditory system even at night, but must listen to sounds 24 hours a day. Bower was obviously unfamiliar with the efferent fibers of Rasmussen (22) and the studies showing the ability of these efferent fibers to turn off the auditory receptors.

Another "rehearsal" function may well be the cooing and babbling activity that even deaf babies produce. Normally-hearing babies stop babbling at about 6 months of age, as do deaf babies. However, the normal baby again picks up vocalization around a year of age, and as any parent knows, never stops vocalizing from then on.

A more logical explanation of such abilities which appear, disappear, and then reappear would be that the Phase 1 appearance of the skill is a pre-programmed rehearsal of the activity or one might even say a "warm-up" of the system that allows the organism to be prepared for the later, more conscious reappearance of the skill. It is as if nature provides for a reflexive involuntary animation — a flexing of the linguistic muscles — in order to warm up the functions that will then lie dormant until the time comes for them to be put into permanent use.

Summary

There appear to be speech processing mechanisms available to the infant at birth and probably well before birth. The mechanisms require only the hearing of acoustic signals that have speech dimensionality to be activated. From an acoustic point of view these actions are reflexive, and possibly audiologists may be able to demonstrate that they comprise some sort of acoustic preadaptive signal-response activity. If so, they are the basis for the infant's utilization of its innate knowledge of language.

CHABA (From p.6)

tical characteristics for tinnitus masking devices. A consequence of this review and evaluation should be the identification of areas in which future research will prove illuminating.

Additional projects which are planned in the immediate future are to develop working groups on presbycusis, techniques for aiding those with a hearing handicap, human response to the sonic boom, and development of a hearing compensation formula.

Starting fiscal year 1981, which commences December 1980, there will be two new sponsors of CHABA and the Committee on Vision, the Food and Drug Administration and the National Institute on Aging.

NRC COMMITTEE ON HEARING, BIOACOUSTICS, BIOMECHANICS Membership List

CHABA PROJECTS SUPPORTED BY OUTSIDE FUNDS

Occasionally a sponsor (or, now and then, a federal agency that is not currently a sponsor) will request an activity of CHABA that cannot be conducted within the fiscal constraints of the core funding. Whenever this happens an independent committee is usually established with its own study director for the purpose of satisfying the request. Some examples of this in the past are the Committee on the Evaluation of Sound Spectrograms. This committee was established at the request and sponsorship of the Federal Bureau of Investigation. They were concerned with the validity and reliability of voiceprints. It was clear to CHABA that this activity would go far beyond the usual working group constraints in both time and cost, so an independent committee was established with its own study director. This led to the publication of a report entitled "On the Theory and Practice of Voice Identification." On another occasion, the Environmental Protection Agency asked for assistance concerning transportation noise and its societal consequences. Again a Committee was established entitled the Committee on Appraisal of Societal Consequences of Noise Abatement and developed a report entitled "Noise Abatement: Policy Alternatives for Transportation." Similarly, the Federal Aviation Administration came to CHABA and asked for assistance in evaluating the community response to the Concorde as it first flew into Dulles Airport. Again a committee was established with its own study director. It was the Committee on Community Reactions to the Concorde and it published a report entitled "Community Reaction to the Concorde: An Assessment of the Trial Period at Dulles Airport."

On other occasions CHABA has seen fit to work with an independent established Committee of the National Research Council and provide what inputs they can to that Committee. A good example of this would be the Committee on SST-Sonic Boom. CHABA staffed the Subcommittee that was concerned with human response to the sonic boom.

Other segments of the Committee considered problems such as response of buildings and structures to the boom, the possibility of alleviating the boom through aerodynamic modifica-

tion, the insurance risks involved, the financial problems in federal funding of the prototype development of the supersonic transport, etc. Early on, CHABA answered a question concerning whether the sonic boom would damage hearing by stating flatly that it was two orders of magnitude lower than the level of an impulse required to damage hearing. In this case CHABA came out in what might be considered a favorable posture toward the aircraft industry and the development of the SST. A few months later when the research report on the FAA supersonic overflights of Oklahoma City was made available, CHABA members read this report with interest and stated that the Supersonic Transport, as designed with a 2.7 psf cruise boom, would not be tolerated by a large percentage of the population. Therefore, the SST should be considered only for transoceanic flights, not transcontinental. This position was held rigorously by the CHABA members on the sonic boom committee and it was only after three years that the parent committee agreed and the resulting statements by the committee, based in large part on the response of people, augmented the decision of the federal government not to fund the development of the prototype SST, since it would not be cost beneficial for transoceanic use alone.

On several occasions CHABA has accepted incremental funding from NASA of approximately \$20,000 per year to conduct a series of meetings that were held about every two years. These meetings led to publication of the First, Second, Third, Fourth, and Fifth Symposium on the Role of the Vestibular Organs in Space Exploration, a series still considered to be of great value.

As an example of another kind of non-core funding, CHABA accepted an additional \$20,000 from NINCDS for the purpose of funding a supervisory working group to guide an individual scientist who spent six months doing a comprehensive review entitled "Noise and Children: A Review of the Literature."

CHABA plans to continue such projects and cooperative efforts in the future.

Decibel (From p.5)

sion has ruled. OSHRC relieved Duriron, Inc., of responsibility for citation alleging a serious violation of the occupational noise standard because the company "made reasonable efforts to protect its employees from excessive sound levels" that could not be alleviated by engineering controls.

One can easily see that the proper selection, fitting, and use of ear protectors is not the simple task that many assume it to be. Further, we cannot accurately predict how much protection will be afforded a wearer unless he is properly evaluated with and without plugs in a sound field. Consequently, proper fitting could cost considerable money. This aspect of "Hearing Conservation" has not yet been subjected to cost analysis.

There is one other factor that makes many of us view blanket use of ear protectors with extreme caution. A number of us working in Industrial Hearing Conservation programs have seen an increase in outer ear infections in those industries that involve a dirty work environment and whose employees continuously use some type of ear plugs for protection; and for those who use ear muffs and work in hot environments. Furthermore, the wax buildup is becoming an ever-increasing problem for those who use ear insert protectors. The plugs seem to "push back" the wax in the canals and retard its normal movement to and elimination at the concha. Cautious use of ear protectors, cleanliness and a sterilization program would solve some of this problem. But again, at what cost and at what level of efficiency?

These are things we know about ear protectors, and we are learning more each day. We also know that continued exposure to noise will cause permanent loss of hearing acuity. What we don't know is actually how much noise, over what period of time, in what environment, what type of noise, and to whom it will cause damage. More ammunition for the battle!

We know some of the answers but even these are vague. One of the major problems in setting criteria for protection of the employee is that there is a tremendous difference between the susceptibility of one over another. Dr. Aram Glorig, who has been involved in Industrial Audiology longer than most of us, refers to "hard," "soft" and "normal" ears in regard to the damaging effect noise has on different people (2). There is also a tremendous difference in the noise one finds in industry and the way it affects different people.

One of the reasons we cannot state without hesitation what is damaging and to whom, is that we are restricted in experimenting with humans. The other primary handicap is that long range studies on large groups of workers are difficult because our population is mobile and prone to change jobs over prolonged periods of time. Hopefully the questions of who, what, where, when and why in regard to noise will be answered in the future, but it will be a long process.

The major study that many thought would answer some of these questions was the Inter-Industry Noise Study referred to earlier. Unfortunately it got underway at a time of recession and job instability. The results of the study were looked forward to by industry for it was speculated they would show that noise may not be as devastating a factor in employee health; or at least, would produce clean cut guidelines for solving our decibel dilemma. Yet now that the first part has been concluded rest assured that its reliability will be attacked with vigor. We quote from the summary of the study that appeared in the Journal of Occupational Medicine in May 1978 (20):

Within the range of 82 to 92 dBA, differences in noise intensity had no observable "effect" on hearing level. That is, the hearing levels of workers at the upper end of the noise intensity exposure were not observa-

bly different from the hearing levels of workers at the lower end of the noise exposure. Age was a more important factor than duration on the job in explaining differences in hearing level within any group. Comparison between experimental and control subjects were made on an age-adjustment basis.

Differences between females exposed to 82 to 92 dBA and their controls were small and were statistically significant at 500, 100, and 2000Hz. Levels in the noise-exposed group significantly exceeded those in the control group at 3000, 4000, and 6000Hz by approximately 6 to 9 dB. At 8000Hz, differences again became not significant.

There was no real evidence of a difference between noise-exposed workers and their controls with respect to the changes in hearing levels during the course of their follow-up one and two years after initial audiograms. Changes were negligible for both groups.

Interestingly enough the editorial by Robert B. O'Conner (19) that followed the study ended with:

The dispute continued as to whether the standard for control of noise to prevent hearing loss should be set at 90 dB or 85 dB. From this study it appears that 90 is as protective as 85, as far as women's hearing is concerned. In the case of men, if a small amount of hearing loss in frequencies that are well beyond the speech range is considered unacceptable, then this study supports a standard of 85 dB.

Only time will tell whether our decibel will be allowed to leave the battlefield. Unfortunately past experience indicates that the battle will be prolonged until we have more specific data on which to declare peace. Until then — let's at least try not to add to the din!

P.S. The Battle of the Decibel was ended on January 13, 1981, when the Occupational Safety and Health Administration approved the final requirements for hearing conservation. Historians will now devote their efforts to deciding who won and who lost.

**AAS ANNUAL
MEETING
NEW ORLEANS
NOV 21st**

CALENDAR OF EVENTS

March 1981 22-27

2nd INTERNATIONAL CONFERENCE ON CHOLESTEATOMA AND MASTOID SURGERY, Hilton Hotel, Tel Aviv, ISRAEL. Sponsor: The Tel Aviv Univ., Sackler Sch. of Medicine, the Weizmann Inst. of Science and the Univ. of Minnesota, Dept. of Oto. Fee: \$280 U.S.; Residents/Fellows \$140; Extra Persons \$100. 22 hrs. AMA Category I credit. CONTACT: The Secretariat, 2nd International Conference on Cholesteatoma and Mastoid Surgery, P.O. Box 16271, Tel Aviv, ISRAEL/call 03/255367.

23-25

CURRENT CLINICAL CONCEPTS IN OTOLARYNGOLOGY 1981, Eden Roc Hotel, Miami Beach, FL. * Sponsor: University of Miami School of Medicine, Dept. of Otolaryngology. 15 hrs. AMA Category I credit. Chairman: James R. Chandler, M.D. CONTACT: Betty Howard, Univ. of Miami School of Medicine, Div. of CME D23-3, P.O. Box 016960, Miami, FL 33101/call 305-347-6716.

* (In conjunction with Pan-American Symposium on Trauma of the Head and Neck.)

27

COMMUNICATION DISORDERS, New York, NY. Sponsor: The Dept. of Otolaryngology and the Page and Wm. Black Post-Graduate School of Medicine. Asher Barr, Ph.D., and Guest Lecturers. Fee: \$35.00. 7 hrs. AMA Category I credit. CONTACT: Director, The Page and Wm. Black Post-Graduate School of Medicine, Mt. Sinai School of Medicine, One Gustave L. Levy Pl., New York, NY 10029/call 212-650-6737.

27

HEALTH CARE DELIVERY FOR DEAF PATIENTS, Washington, D.C. Co-sponsors: The Catholic University of America and Gallaudet College. CEU through The Catholic University of America School of Nursing. CONTACT: Connie H. Knight, or for Registration Information, Terri Baker, The National Academy of Gallaudet College, Kendall Green, Washington, D.C. 20002/call 202-651-5480.

29

1ST INTERNATIONAL SYMPOSIUM OF RECENT ADVANCES IN EAR SURGERY, Palestine Hotel, Alexandria, EGYPT. Sponsor: Alexandria School of Medicine. Chairman: A. Belal, Jr., Assoc. Prof., ORL Dept., Alexandria School of Medicine, Alexandria, Egypt/phone Alexandria 42845.

APRIL 1981

3-4

ENG INTERPRETATION, San Diego, CA. CONTACT: Marion Servos, Instrumentation and Control Systems, Inc., 520 Interstate Rd., Addison, IL 60101/call 312-543-6200.

25-May 3

DIVING MEDICINE IN DEPTH: AN ADVANCED PROGRAM, Flamingo Beach Hotel, Bonaire, Netherland Antilles. Prerequisite is attendance at Basic Program, 28 hrs. AMA Category I. Sponsor: Human Underwater Biology, Inc., and the Undersea Medical Society. Fees: \$350 for academic program; other rates vary. 30 hrs. AMA Category I credit. CONTACT: Program Coordinator, Dept. M-101, Human Underwater Biology, P.O. Box 5893, San Antonio, TX 78201/call 512-492-9395.

26-May 2

POSTGRADUATE COURSE IN EAR SURGERY, Nijmegen, the NETHERLANDS. Sponsor: Ear, Nose and Throat Dept. of the Univ. of Nijmegen. CONTACT: Prof. P. van den Broek, Philips van Leydenlaan 15, 6500 HB Nijmegen, the Netherlands.

MAY 1981

2-9

HEARING HEALTH CARE TEAM CONFERENCE, Caribbean Cruise from San Juan on the Sun Princess. Sponsor: Dept. of Speech Communication, Oregon State Univ. CME credit available. CONTACT: Paul J. Willoughby, Ph.D., Cruise Coordinator, 12389 N.W. Kearney, Portland, OR 97229/call 503-228-9497 or 646-8628.

8-15

COMBINED OTOLARYNGOLOGICAL SPRING MEETINGS, The Bayshore Inn, Vancouver, B.C., Canada. The following societies will be participating:

May 8 The American Society of Ophthalmologic & Otolaryngologic Allergy
May 8 The American Neurotology Society
May 9-10 The American Otological Society
May 10-11 The American Laryngological Association
May 11-12 The American Broncho-Esophagological Association
May 12-14 The Triological Society
May 13-15 The American Academy of Facial Plastic & Reconstructive Surgery
CONTACT: Harry W. McCurdy, M.D., COSM Coordinator, The American Council of Otolaryngology and Head & Neck Surgery, 1100-17th Street, N.W., Suite 602, Washington, D.C. 20036/call 202-659-4591.

15-16

NEW DEVELOPMENTS IN NEUROLOGY AND OTOLARYNGOLOGY, Springfield, IL. Sponsor: Div. of Oto., Dept. of Surgery, Southern Illinois University School of Medicine. 14 hrs. AMA Category I credit. CONTACT: Horst R. Konrad, M.D., Chairman, SIU School of Medicine, Dept. of Surgery, P.O. Box 3926, Springfield, IL 62708/call 217-782-5880.

23

HEALTH CARE DELIVERY FOR PATIENTS, Philadelphia, PA. Co-sponsors: The Catholic University of America and Gallaudet College. CEU through The Catholic University School of Nursing. CONTACT: Connie H. Knight, or for Registration Information Terri Baker, The National Academy of Gallaudet College, Kendall Green, Washington, D.C. 20002/call 202-651-5480.

25-26

CONTROVERSIES IN OTOLARYNGOLOGY, New York, NY. Sponsor: THE Dept. of Otolaryngology and The Page and Wm. Black Post-Graduate School of Medicine. Course Director: Frank E. Lucente, M.D. Fee: \$225; Residents and House Staff \$125. 14.5 hrs. AMA Category I credit. CONTACT: Director, The Page and Wm. Black Post-Graduate School of Medicine, Mt. Sinai School of Medicine, One Gustave L. Levy Pl., New York, NY 10029/call 212-650-6737.

JUNE 1981

10-13

THE 5TH ANNUAL FITZ-HUGH SYMPOSIUM: PEDIATRIC OTOLARYNGOLOGY. The Boar's Head Inn, Charlottesville, Va. CONTACT: University of Virginia School of Medicine, Box 368-Medical Center, Charlottesville, VA 22908.

11-13

PEDIATRIC OTOLARYNGOLOGY '81, Galveston, TX. Sponsor: Dept. of Oto., University of Texas Medical Branch, Galveston. Fee: \$180. 20 hrs. AMA Category I credit. Guest Faculty: Drs. Robin Cotton and Sylvan Stool. CONTACT: Chairman, John K. Jones, M.D., Dept. of Oto., Univ. of Texas Medical Branch, Galveston, TX 77550/call 713-765-3633.

AUGUST 1981

2-6

F.T. HILL 22ND ANNUAL SEMINAR IN OTOLARYNGOLOGY, Waterville, ME. Sponsor: Colby College and the Mid-Maine Medical Center. Fee: \$270. CONTACT: Colby College, Mayflower Hill, Waterville, ME 04901.

5-7

GREAT DEBATES IN OTOLARYNGOLOGY, Seattle, WA. Sponsor: Univ. of Washington in cooperation with Washington State Medical Association. CONTACT: Univ. of Washington, Div. of CME, SC-50, Seattle, WA 98195.

SEPTEMBER 1981

21

ANNUAL MEETING OF THE AMERICAN AUDITORY SOCIETY, New Orleans, La. (See Page 1 for details.)

20-23

AMERICAN ACADEMY OF OTOLARYNGOLOGY AND HEAD AND NECK SURGERY ANNUAL MEETING, New Orleans, LA. CONTACT: Ruth C. Enquist, Director of Meet-

ings and Membership, AAO, 15 Second St., Rochester, MN 55901/call 507-288-7444.

NOVEMBER 1981

20-23

AMERICAN SPEECH-LANGUAGE-HEARING ASSOCIATION NATIONAL CONVENTION, Los Angeles, CA. CONTACT: Frances J. Johnston, Ph.D., Director, Convention and Meetings Div., American Speech-Language-Hearing Association, 10801 Rockville Pike, Rockville, MD 20852/call 301-897-5700.

MAY 1982

1-8

Vol. 5, No. 2

Spring, 1980

I Remember :

The International Audiology Society

By Aram Glorig

Aram Glorig

Since this is the year for the International Audiology Society to meet, it is appropriate that perhaps a short history of this society be published by the younger society known as the American Auditory Society.

When I first approached this task, I thought that it would be rather easy to do, but having written to quite a number of members of the society who were knowledgeable about its beginning, I find it is much more difficult than I expected, particularly if it is to be accompanied by photographs etc., which make the article much more interesting.

Consequently, in order to meet a deadline for the April

issue, Marion has asked me to write a short and brief history taken from my own memory and from a few suggestions here and there. You will probably all remember—that is, those of you who are gray haired enough—that audiology had its beginnings in the Army hospitals during World War II and certainly, shortly after World War II ceased. My first contact with any organized activity as far as audiology was concerned, was in 1946 when I became Director of the newly formed Walter Reed Army Hospital Audiology and Speech Correction Center. Shortly after this, as a matter of fact in 1948, the first conference on audiology was held in Stockholm in September. At that time there was no organized society, but quite a few well known individuals in the field of audiology gathered together for a conference under the immediate sponsorship of Gunnar Holmgren of the Karolinska Institute in Sotockhom, Sweden. The conference participants were men like Carhart, Canfield, Glorig, Homlgren, Johansen, and Bill Hardy. I believe Dick Silverman and Hal Davis were there also.

The year 1948 marks the beginning of the International Audiology Society, but it was not actually organized as a society until 1952. Prior to that there were conferences on audiology and courses in audiology.

Some of the material I have includes notes on some very interesting events. In 1948, under the initiative of Prof. Holmgren, 40 participants representing 16 countries attended the conference which I mentioned above. In 1959, it was decided that a committee which had been appointed in 1948 to study the problem of organizing audiology should be enlarged, but it was not thought at that time that the founding of a "great society" was yet appropriate. In 1951, again under the initiative of Prof. Holmgren, 40 teachers with 200 participants from 23 different countries attended a second course in Sweden. In 1950, the first executive committee of the society was chosen. The President at that time was Prof. Lüscher, Vice President was Prof. Tato, Prof. van Dishoeck, and Prof. Langenbeck.

(cont. on page 2)

Graham, et al Calls For Papers-Downs is Carhart Lecturer

The annual meeting of the American Auditory Society will be held from 9 to 5 on Thursday, November 20, 1980, in the Buerki Auditorium of Henry Ford Hospital in Detroit, just prior to the American Speech, Language and Hearing Association convention.

The theme is The Hearing Impaired: Rehabilitation Routes. Papers concerning possible medical, surgical, educational or amplification approaches to rehabilitation are hereby invited. Clinical research experiences, basic research studies, however remote, if they have long range implications for rehabilitation of the hearing impaired, including children or adults are solicited.

A strict 12 minute time period will be allotted for each presentation with a three minute discussion following. Please submit a 75 word abstract of the proposed presentation to:

A. Bruce Graham, Ph.D.
Division of Audiology, Speech and Language Pathology
Henry Ford Hospital
2799 West Grand Boulevard
Detroit, MI 48208

The other Program Committee members are Michael Paperella and William Ely. The original deadline for receipt of abstracts was May 20, 1980, but has been extended to June 10, 1980. Mrs. Marion Downs, professor of audiology at The University of Colorado Medical Center in Denver, and Editor of Corti's Organ has been chosen as this years Carhart Memorial Lecturer. Complete details and a preliminary program, will be published in the Summer/Fall issue of Corti's Organ.

Mrs. Marion Downs

When one enters a new decade, one tends to set back and look at where one has been and/or try to decide where one should go. Neither the American Auditory Society nor I happen to be at the end of our personal decades, however, it does seem as we begin the 1980's that as a Society we might look forward to some of the problems and some of the possibilities of the next decade.

Since my crystal ball is, as usual, underneath a pile of papers on my desk it is difficult to be sure what the future will hold. But a few thoughts come to mind which I would like to share with you. Your projections and prognostications may be different, but maybe our thoughts will overlap.

It seems to me that one problem which still faces us is lack of good communication. Clearly one of the aims of the American Auditory Society has been to draw together individuals from the various disciplines which are concerned with hearing and hearing impairment. Our society has provided a forum for (note alphabetical listing) audiologists, members of the hearing aid industry, and physicians (otologists, otolaryngologists and others) to talk together, to listen together and to learn together. In most instances it has seemed to me that communication has been facilitated and that the members of our society have been able to communicate openly and well with one another. Most of the sniping which has occurred among our disciplines has tended to occur outside of this society. It seems, therefore, that we should use our society as a place where members, regardless of discipline or background, can exchange information and ideas to better learn how to help the hearing impaired. It has been noteworthy that this society has tended to be more interested in scientific presentations, (along with skiing, travelling, and partying) than in territorial rights. I hope that state prevails during the next decade and beyond. The edge of my crystal ball (hiding under CORTI's Organ) suggests that will happen.

From a professional viewpoint, the next decade should be one in which we begin to make more and more breakthroughs in the area of rehabilitation. Tremendous advances have been made in the last two decades in the definition of hearing impairment and in medical and surgical treatment for hearing loss. No doubt advances in these areas will continue during the next decade. The precision with which the site of the hearing problem can now be identified, and the definition of that problem appears to be increasing geometrically. However, within the last decade we have again begun to pay more and more attention to the individual whose hearing loss cannot be treated medically or surgically with current techniques. Al-

Editorial:

It's sad to think that a whole generation of audiologists and otologists has grown up without knowing about the early contributions of such organizations as the International Audiology Society and the Committee on Hearing and Bioacoustics of the National Academy of Sciences. In this issue Corti's Organ begins to remedy that gap in the education of the new generation, and will continue in the next edition.

What was mind-blowing to those who participated in early International Audiology Congresses was to learn to know personally some of the giants of early Audiology and Otolaryngology. The Americans: Glorig, Carhart, Davis, Silverman and Hirsh represented towers of intellect, innovation. The Europeans too were unique; most combined otology with audiology: the imposing patrician Dr. Lüscher of Switzerland, the jolly and immensely effective Dr. Van Disboeck of Holland; the august and dignified Dr. Wohlstein of Germany; the gentle, concerned Henk Huizing of Holland; (Huizing and E. König of Switzerland (Editor of Audiology) were the two physicists - turned - audiologists); the handsome and impressive Drs. Portmann from France, pere et fils et femme; the fun-loving, aristocratic Swedes, Drs. Barr, Holmgren and Wedenberg; the intellectual Dr. Werth of Israel who was the efficient medical officer in charge of health during the siege of Jerusalem; Drs. Berruocos of Mexico and Tato of Argentina, who furnished the Latin flavor; the charming, humane Dr. Edith Whetstone of England - and a host of other marvelous characters.

The International Congresses comprise a United Nations of Audiology - a forum where audiological activities in other countries are quickly assimilated, and the fellowship between nations bespeaks One World. It is worth attending at least once in a lifetime.

Who knows? World Fellowship may become addictive. Try it.
MPD/RJR

Letters from England

(The following letter was not able to be published in the fall issue, but is belatedly presented for interest)

Dear Editor,

The arrival of Corti's organ has remained a most pleasant occasion and the last issue was no exception. Profusely illustrated it revived some enjoyable memories of many friends and of the Columbus meeting I have reported on before. What a tragic loss that our Guest of Honour at that meeting the great, in every respect, Sven Ingelstedt has died and will no longer enliven our meetings. He will be sadly missed.

Mr. Ear, as you call Dr. Glorig adds lustre to any occasion and looks handsome and impressive in his photograph. Your Foreign Editor on the other hand in regard to his own picture, could not help recalling Oscar Wilde's comment: "I have no objection to the truth but I would have preferred a little flattery"...

Incidentally there was a mistaken identity in your first photo showing in fact not Dr. Wilson but Berny Colman from Oxford. There was a stimulating Course organized by our Oxford colleagues in July before the most successful British Academy meeting in Birmingham. At the Oxford meeting Professor Taylor from Manchester University the world famous audiologist delivered the second LIVINGSTONE Memorial lecture. The late Gavin Livingstone, as you know, developed some new methods for the reconstruction of the closed or malformed external ear.

Talking of meetings we have just come back from a most enjoyable meeting of the Collegium Otolaryngologicum Amicitiae sacrum held in Budapest in September and attended by about 120 members but only few from the USA. Immunology and its role in otology was ably presented under the chairmanship of the President of the meeting Professor L. Surjan from Budapest and his team (including his son a pathologist). Professor Naumann from Munich and the prolific Professor Palva from Helsinki were other contributors to this important topic.

The fine weather and excellent organization contributed to the success of the conference in the splendid Hilton, and gave the opportunity for the renewal of old friendships, a most important function of the Collegium.

A highlight of the meeting was Don Harrison's description of the larynx of the Giraffe (a tall story?).

We shall be looking forward to the next meeting in San Francisco (if we can afford it) and the following Symposium in Electron microscopy of the ear to be held at my second alma mater the splendid Ear Research Institute in Los Angeles. The response to Bill House's call for papers has been excellent.

Imre Friedmann

I Remember...

The Secretary General was Dr. Trenque. Members of the committee were Michelle Arslan, Raymond Carhart, Terrance Cawthorne, Dr. Clere, Hollowell Davis, Harold Ewertsen, Aram Glorig and H.C. Huizing.

Similar notes that I have run across are very interesting. A few of these follow: Gunner Holmgren in 1950 stated that audiology is a new term, early used by W. Hargrove, Norton Canfield, Raymond Carhart and Hollowell Davis. In 1948, Norton Canfield said "Audiology considers everything that can be said to be of aid or detriment to life from sounds which can or should be heard." Again in 1950, Gunnar Holmgren said that "Audiology involves and presupposes team work between several different branches of science; anatomy and pathology, physiology and neurophysiology, physical acoustics, psychology and psychiatry, social sciences, and first and last, otology, the science of ear diseases which is the central and leading branch in this comprehensive team work." These things were said approximately 30 years ago and I do not think that the concept that they express has changed in principal over the 30 years.

The Journal of the International Audiology Society also has a very interesting beginning. In 1952, there were two volumes printed, in 1954 only one, three in 1955, one in 1956 and then in 1964 the journal was changed in terms of the editor who was Prof. van Dishoeck and published in Leiden, Holland. The new editor appointed was Ernest König and the new publisher was S. Karger located in Basel, Switzerland. I think that it would be safe to say that the journal has become an international

I have to end on a very sad news of the death of the Doyen of British audiology and otological pathology Dr. C. S. Hallpike. Others more competent than I will pay tribute to his great work. I have been encouraged by his great interest in the pathology of the inner ear and his entirely scientific approach to its problems.

That wonderful man Pope John Paul the Second has been speaking of peace and reconciliation everywhere. Why is it so difficult to achieve. Sacred friendship, the motto of the Collegium, should be our goal too.

I. Friedmann
London, Autumn 1979

My dear Editor,

A previous letter may not have reached you with my congratulations to Dr. Glorig's awards and honours, so well merited by his pioneering contributions to audiology and his continued research work at the Ear Research Institute. Ad multos annos!

The last issue of Corti's Organ brought back most pleasant memories of the Columbus Symposium marred only by the knowledge of the death of our great friend Sven Ingelstedt. His vitality and energy will be sadly missed at all our meetings.

Talking of meetings I have referred briefly to the stimulating conference of the Collegium in Budapest last September under the able Presidency of Dr. L. Surjan who will also be presiding over the next International Congress to be held in Budapest in 1981 which it is hoped all will be able to attend.

Otolaryngology has come a long way since my joining the racket and the list of meetings, workshops gets longer every year. Your workshop in Vail may rightly be called the 'original Winter meeting' which has stimulated various flattering imitations.

British otology has long been focused on the Royal Society of Medicine in London. Always well attended it is going to remain the centre of meetings. Nevertheless the enhanced interest in this field has encouraged the organization of a new Research Society and of several Courses e.g. the 2nd Cambridge Course in Advanced Otolaryngology in July, 1980 and Courses in Pathology at the Institute of Otolaryngology and in Manchester.

Credit in all this is due to the pioneers of British otology, prominent among them, Dr. Charles Skinner Hallpike, C.B.E., F.R.S., F.R.C.S., who died, aged 79, last year. He was an authority on hearing with an international reputation. As Director of the Medical Research Council's otological research unit he contributed greatly with his co-workers, Hood, who has succeeded him, and Margaret Dix, to the advancement of our knowledge of the pathology of the inner ear.

Pathologists have appreciated the high standard of historical technique demanded by Hallpike in the study of the temporal bone, and the illustrations of his paper e.g. on the pathology of Meniere's disease—incidentally the first description of endolymphatic hydrops in this condition—bear witness to this excellent work.

Our winter has not been too bad and we have been anxiously following the news of the awful weather, in of all places, Southern California. Weather or no weather the political climate has not improved but that is another story.

I. Friedmann
London

(Continued from pg 1)

standard as far as audiological publications are concerned.

Some of the early meetings were certainly interesting meetings and it was highly gratifying to see the audiological field developing as it did under the leadership of the men who are still known as the "Giants of Audiology." It is also interesting to note that the bulk of the leaders as far as the elderly beginnings of audiology are concerned were medically educated men who had an interest in hearing.

Let it also be noted that about 40% of the men who were involved in the beginnings of audiology were non-medically educated individuals, among those we all know were Carhart, Hardy, Silverman and L. Doerfler. I point this out merely to reiterate what has been said by many of us many times, that audiology is a medically related field and should be so considered by all of us.

One anecdote that I remember clearly occurred during the first or second meeting of the audiology conferences that were held in Sweden. I was teaching a group of about 20 or 25 individuals of mixed nationality. Among these were three Scandinavians, a Swede, a Norwegian and a Dane. Discussions which followed the session amazed me somewhat since I noticed that each of the Scandinavians were speaking in their own language and understanding each other quite well. I asked the Swede how he explained this and he stated that "Swedish is really the official Scandinavian language and Norwegian is a dialect of Swedish, but Danish is a disease of the throat."

Papers and Abstracts

from Otology-Audiology Conference

EFFECTS OF VIBROTACTILE STIMULATION ON THE SPEECH PRODUCTION OF THE DEAF AND DEAF-BLIND

Barbara Franklin, Ph.D.
San Francisco State University

The writer is currently directing a study designed to investigate whether there is an improvement in the speech of deaf and deaf-blind children with vibrotactile stimulation using a tactile belt, the Teleactor. This sensory aid, worn about the abdomen, displays speech sounds as dynamic patterns on a belt of electrocutaneous stimulators. Dr. Frank Saunders, Director of the Tactile Hearing Project at the Smith-Kettlewell Institute, Pacific Medical Center in San Francisco, developed the Teleactor and has previously tested the belt for comfort, reliability, safety, and to a limited extent, for speech recognition.

The subjects in this study are six children with severe to profound, bilateral, sensorineural hearing loss, three from the Marin County Deaf Program and three from the Deaf-Blind Department at the California School for the Blind in Berkeley. The children are presented with a series of consonant-vowel combinations using the vowels /a/, /i/, and /u/. The syllables are presented as 1) a 2-sec sustained utterance (to assess the child's ability to control articulators in sustaining a vowel), 2) a 2-sec 2 syllable utterance, and 3) a 3-syllable utterance, uttered at a 3/sec rate (approximating the rate of normal speech). The training stimuli are presented by videotape, and the children's responses are recorded under 2 conditions, one while wearing their hearing aids with the vibrotactile aid, and the other with hearing aids alone. An on-going comparison is being made of the responses of the children in each training session with and without the tactile belt.

A spectrographic analysis is made of selected suprasegmental and acoustic features, including:

1. Rhythm as measured by length of each syllable and entire utterance
2. Manner of articulation, such as plosive, nasality, affrication, etc.
3. Place of articulation, such as labial, alveolar, velar, etc.
4. Vowel formants

As a result of the field testing to date it has become apparent that the belt, in its present design, does not optimally reflect the acoustic properties of speech sounds. The intensity of the sensation at each of the 32 stimulators reflects the amount of energy present in each band, over a range of 30 dB. I have proposed that the sensitivity level of the stimulators be varied to reflect the energy present in the various frequency areas of the speech spectrum. A series of psychoacoustic experiments will be conducted to establish the equivalent of phon curves for the skin.

At the present time, the frequency range has been divided into 32 channels, at approximately $\frac{1}{4}$ octave intervals. However, this spacing does not reflect the distribution of speech information throughout the frequency range. I have proposed dividing the frequency range into approximately 18 channels representing areas of concentration of speech energy. A re-designed belt will be available Fall '80 for comparative field testing with the present belt.

I want to thank my doctoral students, Connie Schimmel and Deborah Bremer for their assistance in the data collection, and my masters students, J. J. Libbon, Ivy Braun, and Chris Atkinson for their assistance in the data analysis. This project is supported primarily by a two-year NIH grant awarded to Dr. Frank Saunders at the Pacific Medical Center in San Francisco, and in part by an NIH Biomedical Research Support Grant awarded to me at San Francisco State University.

STONES, BONES & TEMPORAL BONES

LaVonne Bergstrom, M.D.

UCLA

In a number of disorders of connective tissues formation, calcium metabolism and renal disease there may be profound congenital or delayed effects on the function of the ear. In some of these entities temporal bone pathology, tomographic or surgical findings are known, although in many instances the number of published cases is small.

For the purposes of this presentation the available case material was classified into 1) systemic disorders of bone formation; 2) renal disorders resulting in stone formation; 3) absence of ear stones (otoconia); and 4) ectopic inner calcification.

Primary bone disorders were subclassified into these congenital ones which often result in softening of the bone or in fractures (osteogenesis imperfecta), osteopetrosis - benign and malignant forms; hypophosphatasia, hyperphosphatasia; those usually genetic disorders in which the base of the skull becomes densely overgrown with excessive bone which may fix ossicles or impinge on labyrinthine spaces or nerve canals (osteopetrosis, craniometaphyseal dysplasia, frontometaphyseal dysplasia, craniodiaphyseal dysplasia, sclerosteosis, hyperostosis corticalis generalisata, acromegaly); those causing disproportionate dwarfism (achondroplasia, diastrophic dwarfism, Kniest's, spondyloepiphyseal dysplasia, metaphyseal dysostosis and campeloc syndrome); those having progressive replacement of bone by abnormal tissue (Paget's, osteitis fibrosa cystica, fibrous dysplasia); those causing bony deformity (arthroopthalmopathy, osteodysplasty, Paget's) and bony disorders often localized to the temporal bone (otosclerosis, osteomas, exotoses).

An example of a biochemical disorder leading to kidney calcifications, renal disease, progressive hearing loss and ataxia is primary hyperuricemia.

Animal models and a human case recently reported show a combination of cutaneous hypopigmentation and absent otoconia.

Ectopic calcification in the cochlea, especially in or near the stria vascularis, occurs in a variety of disorders. Displaced otoconia may have been observed in a number of cases of Scheibe malformation.

(Note: some disorders are listed twice because they have more than one predominant characteristic.)

CONGENITAL HEARING LOSS—THE SECOND LOOK

LaVonne Bergstrom, M.D.

UCLA

This concept is borrowed from Wangenstein's surgical re-exploration of the operative site for recurrent abdominal

cancer. However, in the present context it refers in general to periodic re-evaluation of revision of diagnosis of the congenitally hearing-impaired child in whom the etiology of the hearing loss is uncertain or unknown at first presentation.

Specific reasons for re-evaluation or change in diagnosis include, but are not limited to: 1) repeat audiometry which may reveal progression of loss or unsuspected opposite ear involvement; 2) overlooked historical items; 3) overlooked physical findings; 4) suppressed family history; 5) false positive family history; 6) red herrings; 7) wrong initial diagnosis; 8) mental block phenomenon; 9) progressive concomitant disease; 10) to complete the workup; 11) second thoughts; 12) new information from a consultant; 13) new scientific knowledge; 14) new technology; 15) to determine how the child is doing.

Case examples of each of these were presented.

(Abstracts continued on Pg. 12)

I Remember

Cont. from pg 2

I would like to close this brief description of the beginnings with a quote from the Statues of the International Society of Audiology under Aims. "The aims of the Society are to facilitate the knowledge, protection and rehabilitation (in its theoretical aspects) of human hearing, and to this end it coordinates and disseminates information, particularly through the holding of regular international congresses and the publication of work of its members. The Society has no political or religious character and any incursion into these fields is expressly forbidden."

As I stated early in this brief exposition, I am gathering data with which to prepare a more lengthy and detailed history of the International Society of Audiology. I hope that you will bear with me in trying to meet the deadline that was imposed upon me by our charming editor of Corti's Organ. I promise to do better in a later article.

Presidents' Message

Cont. from pg. 1

though this group may also diminish during the next decade, it is clear that rehabilitation procedures should and will be enhanced. The hearing aid has shrunk from an object that might best be carried in a backpack to one that can be placed within the ear canal. Its frequency responses have been extended at both ends and flattened throughout until now we are presented with music and with environmental sounds to make listening technical breakthroughs, we can continue to improve our procedures for evaluating hearing aid performance with speech, with music and with environmental sounds to make listening pleasurable as well as intelligible.

The number of people who can be helped by amplification will increase during the next decade. It is to be hoped and believed that procedures for determining the ways to select appropriate instruments and perhaps even that elusive "best possible instrument" will be refined during this decade. Aural Rehabilitation no longer means a weekly course in lipreading supplemented by hearing aid orientation, but means maximizing use of residual hearing, optimizing ones listening environment and utilizing as much sensory input as possible for the understanding of speech and for adapting to ones environment. These techniques will improve during the next decade.

I have no doubt that the members of this society will continue to work together to provide answers to some of the questions which still remain about how the hearing mechanism works in the normal ear and non-normal ear; that they will work together to develop better and more reliable procedures for assessing hearing impairments, for determining its cause, and for remedying the problem through medicine, surgery, amplification and/or rehabilitation. This society provides a meeting place for members of the disciplines most closely involved with the hearing impaired and I hope that through this society many of the questions yet unanswered will find solutions. Although I suspect we will not find all the answers during my year as President, I certainly hope that we will find some.

Recently a class of students at our university prepared a script which had as its underlying thesis, the thought that hearing loss had been abolished (everyone wore their ear protectors, no one used ototoxic drugs, all the "bad" genes were identified, etc.) I wish that would be the outcome of the 1980's but since I don't believe it will, I hope that we will be able to work together to reduce the number of hearing impaired and to help those which remain, live the most productive lives possible.

In short, sometime I think we'll find a boring decade but I don't believe that 1980 will be it. Now, I don't know about you but I think I'm ready to get on with it. Let's do it together.

AAS Membership Directory

(The following individuals were paid members of AAS as of March 1, 1980)

ABEL, DEBRA BERGER
8865 Lynnett St., N.E.
Alliance, OH 44601

ABER, WILLIAM
18 Morningside Dr.
Livingston, NJ 07039

ADAMS, JACK
Northern Interior Health Unit
1444 Edmonton St.
Prince George, BC
Canada V2M 6W5

AHRENS, ROBERT P.
23-15 Broadway
Fair Lawn, NJ 07410

AHROON, WILLIAM A.
Dept. of Audiology
Wayne State Univ.
4201 St. Antoine 5 E
Detroit, MI 48201

ALBRIGHT, PAULETTE
4617 Stuart Av.
Richmond, VA 23226

ALFORD, B. R.
Neurosensory Center
Baylor College of Medicine
6501 Fannin
Houston, TX 77030

ALLARD, J. BRAD
P.O. Box 1871
Columbia, MO 65205

ALLEN, JOHN R.
8527 - 60th Av.
Berwyn Heights, MD 20740

ALLEN, DORIS V.
Wayne State University
Department of Audiology
4201 St. Antoine, 5-E
Detroit, MI 48201

ALLUISI, MARY JANE
15211 Sandia
San Antonio, TX 78232

AMATYAKUL, POONPIT
Hearing & Speech Clinics
Ramathobodii Hosp.-EENT
Rama VI Rd.
Bangkok 4, Thailand
ANDERSON, LLOYD C.
1033 Springfield Dr.
Millbrae, CA 94030

ANDERSON, MARCIA LEE
275 Middleneck Rd.
Great Neck, NY 11023

ANDERSON, VIRGINIA S.
1105 Kings Mountain Dr.
Little Rock, AR 72211

ANDERSON, CHARLIE D.
Tracoustics, Inc.
P.O. Box 3610
Austin, TX 78764

ANDERSON, CHARLES V.
University of Iowa Hosps.
Dept. of Orl/Audiology
Iowa City, IA 52241

ANGELELLI, ROGER M.
Chairman, Dir. of Audiology
Mercy Hosp.
Pittsburgh, PA 15219

ANTHONY, P. F.
662 S. Henderson
Ft. Worth, TX 76004

ANTHONY, W. P.
662 S. Henderson
Ft. Worth, TX 76104

ARENBERG, I. KAUFMAN
U. of Wl. Hosp. & Clinical Sci. Ctr.
600 Highland
Madison, WI 53792

ARICK, JUDITH T.
14 Victoria Ctr.
Newton Centre, MA 02159

ARNST, DENNIS JAMES
Audiology & Sp. Path. Service
VA Med. Ctr.
4150 Clement St.
San Francisco, CA 94121

BACHNIVSKY, VALENTINA
Ent. & Facial Surgery, Inc.
711 River Dr.
Marion, IN 46952

BADGER, JANICE E.
Public Health Speech &
Hearing Clinic
8635 S. Young Rd.
Chilliwack, BC
Canada V2P-4P3

BAILEY, JR., H. A. TED
The Ent Clinic
1200 Medical Towers Bldg.
Little Rock, AR 72205

BAIRD, PATRICIA M.
4939 Garfield St.
La Mesa, CA 92041

BAKER, ASHLEY H.
Neurotologic Assocs.
111 East 77th St.
New York, NY 10021

BALAY, GEORGEAN
1554 Charter Oak Dr.
Rochester, MI 48063

BALLA, LOUIS B.
916 - 19th St., N.W., Ste. 214
Washington, DC 20006

BALMER, WILLIAM F.
6403 West 131st St. Ct.
Apple Valley, MN 55124

BARKER, ANN M.
3319 Spring St.
Davenport, IA 52807

BARRON, DAVID P.
334 Brook St.
Noank, CT 06340

BARRY, S. JOSEPH
Speech & Hearing Ctr.
Univ. of Oklahoma Health Sci. Ctr.
P. O. 26901
Oklahoma City, OK 73190

BARTLING, VICTORIA
1603 Harris Rd.
Philadelphia, PA 19118

BASS, JANICE H.
13309 Sherwood Forest Dr.
Silver Spring, MO 20904

BATE, HAROLD L.
Dept. Speech Path. & Audiology
Western Michigan University
Kalamazoo, MI 49008

BATSHAW, MARILYN SEIDNER
152 Cypress Dr.
Colonia, NJ 07067

BATTIN, R. RAY
3931 Essex Ln. #7
Houston, TX 77027

BAUCH, CHRISTOPHER
805 - 28th St., N.W.
Rochester, MN 55901

BAUER, STEPHANIE LYNN
9035 Moorhead Dr.
Indianapolis, IN 46268

BEASLEY, DANIEL S.
Dept. of Audiology & Sp. Path.
Memphis State University
807 Jefferson Av.
Memphis, TN 38015

BEAUCHAMP, CPT. JAMES A.
Letterman Army Med. Ctr.
Box 1503
Presidio of San Francisco, CA 94129

BEAUMONT, PERSIS T.
S.B.A. Memorial Hosp., Rm. 201
El Dorado, KS 67042

BEAVER, HAROLD G.
Scott & White Clinic
Audiology Section
Temple, TX 76501

BEEBY, GARY J.
Sp. & Hearing Clinic, Hanner Hall
Oklahoma State University
Stillwater, OK 73858

BEGEN, LINDA GAIL
16 Dorothy Pl.
Berkely, CA 94705

BEHNKE, CHARLES R.
VA West Side Hosp.
820 S. Damen Av.
Chicago, IL 60612

BENITEZ, JAIME T.
Director, Div. of Otoneurology
Wm. Beaumont Hosp.
3535 W. 13 Mile Rd.
Royal Oak, MI 48072

BERGER, KENNETH W.
Kent State University
Speech & Hearing Clinic
Kent, OH 44242

BERGSTROM, LAVONNE
Div. of Head & Neck Surgery
Rm. 32-34 Rehab., UCLA
1000 Veteran Av.
Los Angeles, CA 90024

BERKOWITZ, ALICE O.
39 Gramercy Park
New York, NY 10010

AIR BONE GAP, DIPS AND NOTCHES EVALUATION OF COCHLEAR RESERVE IN OTOSCLEROSIS

by Jean R. and J. Bernard CAUSSE

Otolaryngology Clinic

34325 BEZILERS (France)

I. HISTORY

The prediction of the type of stapedial fixation thanks to the audiometric shape before stapedectomy can be useful, not only to foresee the eventual operative difficulties, but also to forecast the final prognosis of the post-operative functional result. Numerous authors have tried to find the relationship between the shape of the Air Bone Gap (ABG) and the remodelling of the niche encroaching the footplate, but most of them have not succeeded. DANIC and ELBAZ (25), GRISTWOOD (28), George SHAMBAUGH (39) admit that no parallelism can be found between the ABG and the importance of the stapedial fixation. We have also tried to solve the problem, but we only partially succeeded.

Rapidly, we found the reasons for our failure in this study, and so we changed our method. There are two main difficulties in the solution of the problem: first, the correlation of the ABG with the importance of the encroachment of the footplate;—second, the accurate evaluation of the bone conduction level. The first difficulty was relatively easy to solve, but the second one, of critical importance, was very deceiving. So, starting from an anatomical point of view, we had great difficulty in appraising the true cochlear reserve in the otospongiotic/otosclerotic disease. We would like to show you our data, our deductions, our arguments, and our doubts too, for we are still doubtful on some points.

Indeed, the problem in predicting the type of stapedial fixation from the ABG shape is less important now that we have the enormous possibilities of impedance-audiometry and X-Ray tomographies of the ossicles and of the niche for the diagnosis. Moreover, the present techniques of stapedectomy allow us to perform the operation safely, whatever the anatomical type encountered may be. But we have persued this idea in this lecture, because it leads to the research of the real value of bone conduction as a method of evaluation of the true cochlear reserve. And this last problem is of great interest in otospongiosis/otosclerosis.

But before going ahead, we would like to explain why we sometimes use the term "otospongiosis", sometimes the more common one "otosclerosis". The two nouns should be used according to the stages of the disease. "Otospongiosis" characterizes the first stage of destruction, the only typical one, whereas "otosclerosis" typifies the very common stage of pseudo-haversian rebuilding. In fact, otospongiosis represents the more important phase of the disease itself with very active microfoci, and otosclerosis is its most common surgical aspect. Consequently, "otospongiosis" should be the name

applied to the disease itself caused by very active microfoci, whereas "otosclerosis" should remain the term for stapedial fixation caused by the terminal second rebuilding state of the niche.

II. PATIENTS AND METHODS

All subjects were tested in a sound-proof test cabin with the audiologist and equipment in a separate control area, also strictly sound-proof. The two cabins are separated by a double sound-proof wall and windows with three glass plates insuring total safety from noise. The audiometers were standard diagnostic audiometers Peters AP5/6 and Madsen OB-70, with TDH.39 earphones and radio-ears B.70A bone conduction vibrators. The speech material was delivered by dissyllabic word lists tapes recorded to facilitate handling. Of course, complete calibration check-ups of the audiometers were made every two weeks, using an audiometer calibrator unit BRUEL and KJAER consisting of a sound level meter, a microphone calibrator with 6 cc cavity and an artificial mastoid 49/30 B.C. calibrator. The electrical voltage was controlled by a voltage stabilizer was controlled by a voltage stabilizer.

All the tested subjects were active otospongiotic and non progressive resultant otosclerotic patients, with two control groups (normal and sensorineural without middle ear pathology).

Starting first from the concept that an unknown relationship could exist between the ABG shape and the stapedial fixation, we studied the data collected in 580 consecutive otospongiotic/otosclerotic patients from September 19, 1977 through April 4, 1978. During this period of time, we gathered similar data on a control group of 36 non otosclerotic patients, operated on for another disease. (Tab. 1) The collected data included pre-operative audiometric air conduction and bone conduction testing and operative findings on stapedial fixation type and remodelling of the niche, by two surgeons operating on the middle ear with similar teflon-interposition technique.

As we did not find enough significant correlations between pre-operative ABG and footplate encroachment, we changed our technique of investigation of the possible relationship between audiometric and anatomical data encountered in stapedectomies. And this second study dealt with statistical computerized data collected from 1970 through 1980 on 13,682 patients and related to ABG shape (width, ascending or decreasing type), B. C. curves (chiefly dips and notches involving some defined frequencies), anatomical operative finds and, when possible, bony cochlea pathology by X-Ray investigations (comparative tomographies).

This complex and extensive study gave us interesting and valuable results, which we will analyze in the next chapter, but ended in the disappointing conclusion that it is very difficult to evaluate the accurate bone conduction threshold in pure tone audiometry, thus allowing us to know the real cochlear reserve. And yet, a precise bone conduction level is

the very basis of the shape of the A.B.G.

III. ANALYSIS OF THE RESULTS

1/The first comparative study of the data gathered on pre-operative ABG and operative findings in 580 consecutive patients operated on for otosclerosis by stapedectomy, allowed us to draw up to 6 types of ABG shapes, each corresponding to a special type of remodelling of the niche invading the footplate.

In fact, the average of 67% of exact correlations between the pre-operative ABG opening and the intra-operative anatomical findings concerning the footplate encroachment by the bony remodeling of the niche, appears significant, so far as the percentages of the correlations of ABG-stapedial fixation and those of ABG-remodelling of the niche are similar. The difference (6%) seems due to the mild remodeling of the niche, very difficult to see in the early stages. But these relationships are only of indicative value, because there remains more than 30% in which no correlations can be found.

These unsatisfactory results may be caused by the more or less important middle-ear contribution to bone conduction, for the B. C. occurs not only by the vibrations of the skull communicated to the cochlear fluids, but also by those of the ossicular chain of which the ossicles have a different vibration owing to their mass and inertia. Moreover, the opposition of the phases of the two windows must be taken into account. The bone conduction mechanism is very complex and has not yet been clarified.

2/Consequently, we undertook a second series of research on computerized data collected from 1970 through 1980 on 13,682 patients operated on, and related to ABG shape, B. C. curves and operative findings. This study was long, complex and difficult. It confirmed our previous results on relationship between the ABG shape and anatomical changes in the niche area in otosclerosis. But a close analysis of the bone conduction thresholds rapidly confirmed the notion that too many factors are involved in the B. C. hearing mechanism to allow a sure evaluation of the true cochlear reserve thanks to the B. C. curves in pure tone audiometry.

We found 4 types of notches in B. C. levels:

1/a dip at 500 Hz, which we had for a long time related to vascular factors acting on cochlear blood flow (10,11);

2/a dip at low-mid frequencies (250-500-1000 Hz), presented by JOHNSON, HAWKINS and LINTHICUM (30), as the result of a toxic factor diffusing from an active large anterior otospongiotic focus;

3/a "cookie-bite" curve in cochlear otospongiosis described by SHAMBAUGH (39) and some other authors (16, 41). This shape is now classical, but very often mistaken for genetic deafness and described as an isolated syndrom.

4/the classical CARHART notch, which we explained in 1965 in some papers (8,9), and chiefly in a film on the Teflon Inter-

position Technique. On the whole, this notch shows the middle ear contribution to the pre-operative B. C., but its disappearance seems the consequence of the changes in the labyrinthine fluids pressure after stapedectomy.

But according to post-operative functional results, obviously showing a considerable improvement of the B. C. in pure tone audiometry and the disappearance of the dips and notches immediately after stapedectomy, other factors must be found to explain the various shapes of the ABG, and particularly the B. C. levels.

IV DISCUSSION

We believe that the old concepts of the ABG value and of the B. C. thresholds as giving the true cochlear reserve, must be completed and some of them revised.

1. **ABG value:** the ABG shows the conductive component of hearing loss, but only on the condition that B. C. levels reflect the true cochlear reserve. The considerable improvement of B. C. curves immediately after stapedectomy for otosclerosis makes evident the fact that pre-operative B. C. threshold levels are not its real reflection.

Thus we will only discuss two points related to the mechanism of the opening of the ABG.

A/TYPE I: corresponding to narrow or questionable ABG at low frequencies, combined with diphasic impedance change (on-off effect) in impedance audiometry. Its elicitation allows a very early diagnosis of the otosclerotic stapedial fixation, much better than tympanometry. We have given a mechanical explanation (based on anatomical operative findings, that is the presence of bony spiculae at the anterior third of the oval window rim, and on the mathematical analysis, that is the same response of an elastic system to a deformation, but with a different mechanism for the two inverse peaks, due to a different mass and thus to a different inertia (2, 11, 12, 18).

Our mechanical concept called for numerous criticisms. We have no time to summarize them here. The most interesting is that expressed by LOVE and STREAM (32) in their explanation of this perspective. Their concept does not conflict with our's as they seem to base their opinion on an erroneous interpretation of our schemas. On the contrary, our concept perfectly completes their's, since the respective responses of stapedius and tensor tympani muscles help and amplify the responses of the elastic tympano-ligament-ossicular systems to the disturbance caused by the intense sound stimulus (1, 18). Moreover, the diphasic impedance change does not precise the diagnosis of the otosclerotic disease itself, but only the type of stapedial fixation, without prejudging its origin. But owing to the very frequent coexistence of otospongiotic bony spiculae, already described, and of an on-off effect, it appears as a considerable sign for the presumption of stapedial otospongiotic involvement (in about 90% of cases) (2, 18).

B/TYPE VI: ABG open on the "cookie-bite" B. C. curves chiefly depends on the B. C. threshold levels. The problem of its explanation is half conductive, half perceptive. The conductive mechanism is easily explained by the change in impedance of the middle ear after stapedectomy; so a relative B. C. level is changed in a true B. C. one thanks to the release of the stapedial fixation, as we explained in 1965 (9). But the total recovery of the CARHART notch immediately after a correct stapedectomy implies another factor, that is a change in cochlear hydrodynamics, as we will see later in the study of dips and notches in B. C. audiometry.

2.—Dips at low-mid frequencies in B. C. pure tone audiometry.

The disappearance of the various dips and notches at low and mid frequencies, immediately following stapedectomy, is evidently due to changes in labyrinthine fluids pressures. Studying the same problem that we were working on, RICCI and COLLETTI (35) concluded in 1977 that the bone conduction undergoes systematic changes during stapedectomy both in threshold levels and in difference limens of intensity, mainly at midhigh frequency. They are strictly related to the surgical phase of the operations and they appear to be related to differences in cochlear hydrodynamics, rather than to damage of the sensorineural structures. We totally agree with RICCI and COLLETTI, but other factors must be admitted.

The Dip at 500 Hz, which we first thought to be of vascular origin (10, 11, 15), and the Dip at 1000 Hz, originated by JOHNSON, HAWKINS and LINTHICUM (30), seem indisputably due to pressure changes in labyrinthine fluids and not to an enzymatic or vascular etiology. But we have four main reasons to believe that other factors must be added to the pressional one:

a) the disappearance of these Dips at 500 or/and 1000 Hz immediately follows the stapedectomy, as soon as the pre-operative perilymph hyperpressure is reduced by the opening of the new fenestra in the footplate and by its sealing either by a supple vein graft in the teflon-interposition technique, or by a spontaneous thin membrane surrounding the shaft of the prosthesis in the teflon-piston technique. A pure enzymatic origin could not improve B. C. audiometric curve so rapidly. Only a pressure change of labyrinthine fluids after stapedectomy can explain this rapid improvement.

b) from the anatomical point of view, the correlation between the Dip at 1000 Hz and the anterior focus can be explained by the expansion of this focus towards the area of the cochlear canal, precisely corresponding to the 1000 Hz frequency, whereas an enzymatic action spreading from this anterior focus should diffuse into the labyrinthine fluids and

thus progressively reach other areas. The 1000 Hz dip could not be so precise and so narrow.

c) the 1000 Hz Dip can coexist with a cochlear component due to the enzymatic activity, but it does not depend on this activity. The best proof is given by the comparison between pure tone audiograms, showing a very deep Dip on both A. C. and B. C. in stages II without cochlear component, whereas this Dip is only seen on A. C., and not on B. C., in stages III with a more or less severe cochlear component. An enzymatic origin could not cause such a deep Dip on both A. C. and B. C. curves in the stage II of the first patient (BUCH...Jeanine, n° 790339) and only a Dip on A. C. curve, with a decreasing B. C. of enzymatic origin, in the stage III of the second patient (DUF...Maria, N°775995).

d) only the coexistence of 3 factors: hyperpressure of labyrinthine fluids, expansion of the otospongiotic focus into the bony cochlear duct, and toxicity of the enzymatic activity on hair cells, with a possible predominance of one of these 3 factors according to the case, can explain the various dips and notches in A. C. and B. C. curves encountered at low and mid frequencies in pure tone audiometry performed on otospongiotic/otosclerotic patients. Two practical examples can be drawn out of our numerous data: the first one, CAV...Patricia, n°785031, 19 years old, with a very deep dip on 1000 Hz frequency co-existing with poor vascularized middle ear and labyrinthine fluids hypopressure in spite of the dip and tinnitus at 1000 Hz seems to correspond to an active anterior focus acting by expansion:—the second one, CHAR...Andre, n°775002, 45 years old, having an impressive remodelling of the niche invading the footplate and an important labyrinthine fluids hyperpressure explaining pre-operative tinnitus and vertigos, but with a questionable notch on pre-operative B. C. levels, shows an active otospongiotic process leading to labyrinthine liquids hyperpressure through remodelling of the bony cochlea and troubles of resorption.

In fact, these 3 factors: hyperpressure, expansion and toxic action, have the same origin, that is the enzymatic process which only can explain both the bony remodelling of the cochlear duct and of the vestibule with the resultant resorption troubles and the narrowing of these areas leading to focus expansion and fluids hyperpressure, and the enzymatic toxic action on the hair cells. This enzymatic action could be a reaction against the embryonic cartilaginous remnants, very frequent up to 25/30 years of age in the otic capsule, and the enzymatic mechanism of the balance based on inhibitors resulting from the antigen-antibody conflict. The active otospongiosis of the first lytic stage seems to be an autoimmune disease, leading to the inactive otosclerotic stage of pseudo-haversian bony rebuilding.

3.—Notches at mid-high frequency in B. C. pure tone audiometry. They correspond:

a) to the well known "CARHART notch" often seen at 500/2000 Hz in bone conduction with an ABG related to the stapedial fixation. The conductive mechanism can be attributed to the effect of stapes fixation on inertial B. C. before the operation, the stapedectomy changing this pre-operative relative B. C. into the real B. C. showing the true cochlear reserve post-operatively. But we believe that the modification of labyrinthine pressures caused by stapedectomy, can also explain the total disappearance of the CARHART notch immediately following the operation on the footplate, changing the pre-operative hyperpressure back to normal. We must confess that the only mechanical explanation we gave in 1965 (8, 9) was incomplete and partly unsatisfactory. The addition of the two factors, both mechanical and pressional, is logical and explains the broad area of the impaired frequencies, contrasting with the narrowness of the dips caused by expansion of a focus, or with the site of predilection of low-mid frequency in case of expansion of an anterior focus.

b) to the "cookie-bite curves", described by G. SHAMBAUGH (27, 39) and by our group (19,22) in typical cochlear otospongiosis without any conductive components. A labyrinthine fluids hyperpressure may be caused by changes in resorption of the labyrinthine fluids and by the interference of the disturbances in venous drainage in scala tympani, but we must not forget the specific bony remodelling of the cochlear duct, either in the affected middle and apical turns, or sometimes in the lower basal turn, amplifying the hyperpressure and directly acting on the membranous canal through formation of new lamellar bone in the scala tympani (33, 38). Indeed the absence of ABG is in favour of a mobile footplate in these cases and the mobility of the footplate is conflicting with the theory of hyperpressure as the sole factor of the notch. In spite of the absence of any surgical or histopathological findings on ABG in pure tone audiograms, we agree with JOHNSON, HAWKINS and LINTHICUM (30) on the notion that all of these notched losses without any conductive component are in fact the result of active otospongiosis or resultant otosclerosis.

4.—B. C. progressive decrease at high frequencies. Aging and sensorineural degeneration having been excluded, this progressive B. C. deterioration evidently has an enzymatic origin (13, 15, 19, 20, 21, 22, 24). The toxic action of the trypsin on hair cells slowly causes this degeneration according to our enzymatic concept of the otospongiotic disease, in which the upset of the normal equilibrium between trypsin and alpha 1 antitrypsin causes both the bony rebuilding of the niche leading to stapedial fixation and the bony remodelling of the capsular otosclerosis, as well as the cochlear membranous structures impairment leading to sensorineural hearing loss.

But these descending curves, sloping on high frequency, modify the shape of the ABG, as we have already seen in type IV of the ABG systematization. A close study of the ABG shape in each case allows a correct interpretation of A. C. and B. C. component. There is no problem.

5.—Accurate evaluation of real B. C. threshold levels in pure tone audiometry appears illusive in the light of the above detailed discussion. We must add some other misleading elements to the already mentioned deceiving factors for a precise approach of the true B. C. For instance:

a) The B. C. level measurements have not attained the same degree of precision as those of air conduction hearing, for two reasons: first, we have not yet a satisfactory method of calibration of B. C. transducers, even with mastoid model unit;—second, the aim of the B. C. transducer is to vibrate the bony structures of the cochlea being tested, but it induces vibration of the whole head at the same time. Moreover, if an artificial ear has physical characteristics identical to those of a real human ear, it appears very difficult to have precise devices presenting the same responses in terms of sound pressures to that generated in the real ear.

b) The B. C. levels are not only determined by sound vibrations reaching the cochlear fluids through the skull and through the oval and round windows (34, 39), but also through the whole middle ear, owing to the vibrations of the skull, the tympanic membrane, the ossicles, etc., so far as we could paradoxically say that a B. C. loss may be not significant of a bad cochlear reserve. Only a certain amount of sound energy reaches the cochlea directly through its bony structures, acting on labyrinthine fluids and thus on kinocilia of the hair cells. When the skull is set into vibrations by the B. C. transducer, the inertia of the ossicles in the middle ear may produce a differential motion of the stapes, and therefore of the fluids in the cochlea. It is the basis of the explanation of the CARHART notch and of its disappearance, according to the pre-operative stapedial fixation and its post-operative release, changing both ossicles impedance and fluids pressures.

c) Evidence for sound perception with the labyrinth was demonstrated by BLEEKER, WIT and SEGENHOUT (4), who have shown that in guinea pigs and pigeons with a total cochlear loss caused by CO₂ laser radiation or by total removal of the cochlea, fenestration of the lateral semicircular canal affords a quality of information equal to that obtained by monopolar cochlear implants. Of course, it can hardly be expected that frequency discrimination is possible, but patients with bilateral total cochlear loss and intact labyrinth could, after fenestration and training, obtain a meaningful sensation from sounds, especially for the lowest frequencies.

This extensive, but disappointing study of the B. C. threshold levels, done while investigating the relationship between ABG and remodelling of the niche in otosclerosis, led us to the conclusion that the B. C. in pure tone audiometry testing is not always reflective of the true cochlear reserve. It seems that cochlear changes made evident by post-operative pure tone audiometry, and even by standard air conduction speech discrimination audiometric tests, do not always correspond to a true sensorineural type hearing loss. We agree with M. ROBINSON and S. KASDEN (36, 37) stating that the apparent sensorineural audiometric changes immediately following stapedectomy may be not indicative of a cochlear drop, because the conductive mechanism partially implied in standard measure of B. C. levels, is temporarily impaired by changes in the impedance and some other factors, such as oedema, transudates, blood clots, micro-hemorrhagia in the middle ear (37).

For these same reasons, we generally recommend high doses of Cortison (I.V. Hemisuccinate) for the first five post-operative days and middle-ear inflations either by valsalva or by gentle politzer as soon as the first post-operative day, thanks to a wide vein graft sealing the niche. (15, 23)

V. PRECISE EVALUATION OF THE REAL COCHLEAR RESERVE BY BONE CONDUCTION SPEECH AUDIO-METRY

Working on the same topic, that is the research of a valuable method to evaluate the true cochlear reserve preoperatively in otosclerosis, but without studying together, our group in 1967 (10, 11, 14) and ROBINSON and KASDEN in 1970 (36, 37) drew the same conclusion that only pre-operative Bone Conduction Speech Audiometry can reflect the true cochlear reserve. Our basic concept was the same, but the methods were different, both of them allowing an accurate prognosis of the post-operative functional result in otosclerosis.

1/The Bone Conduction Speech Audiometry recommended by ROBINSON and KASDEN (36, 37). In this test, the pre-operative speech discrimination by bone is an excellent indication of post-operative speech discrimination, much more valuable than pre-operative speech discrimination by air. It gives an accurate indication of the post-operative functional result, but only on the condition that we use a maximum permissible masking on the opposite non tested ear (37), for the B. C. cross-over is very great in otosclerosis. Thus this test cannot be performed if the contralateral non tested ear has been already operated on by stapedectomy.

2/The Bone Conduction Speech Weber Test (SWT) which we originated in 1967 (10, 11, 14), is a simple and sure method, allowing the prediction of post-operative functional result for each ear with accuracy. Our test automatically shows, thanks to the direction of its lateralization, the ear to be operated on

(cont. on pg. 14)

Announcing the P.E.M. System

New earmold construction utilizing acoustic horns and predictable damping characteristics are now available. This innovative technology will result in greatly improved sound quality for speech and music according to E. Robert Libby, President of Associated Hearing Instruments.

These new earmold constructions will provide

- (1) Smoother hearing aid frequency response
- (2) Compensation for loss of ear canal resonance
- (3) Increased bandwidth up to 8000 Hz for wideband receivers

- (4) Greater predictability
- (5) Lower distortion
- (6) Greater economy.

Users have reported more natural sound quality resulting in greater satisfaction. A new concept of hearing aid fitting will probably result from these revolutionary constructions. The original research design and engineering was conducted by Mead Killion, senior research engineer at Industrial Research Products, and Hugh Knowles, President of Knowles Electronics.

These earmold modification techniques will enable the fitter to modify the entire frequency spectrum to 8000 Hz by means of acoustic horns, dampers and vents.

These new coupling systems will

- (1) Preserve the balance between the highs and the lows of the speech spectrum
- (2) Preserve the normal eardrum free field transfer function
- (3) Extend the high frequencies
- (4) Eliminate the peak at 1000 Hz which can be detrimental for many mild to moderate hearing losses.

These molds are called by various names such as 8CR, 6R12 and 6AM.

The following observations have been recorded with these new earmold constructions.

- (1) Improvements in free field speech audiometry in quiet and in noise
- (2) Sound field thresholds with narrow band or warble tones improved significantly, especially at 3000 Hz
- (3) Improvements in judged quality of amplified sound especially music.

Test kits of the P.E.M. System earmold constructions are available for immediate hearing aid evaluation. Write to E. Robert Libby

Air Bone Gap, etc.,

Cont. from pg 13

first, and thanks to the position of its curve, the post-operative functional result to be expected for the ear towards which it is lateralized. Moreover, it does not need contralateral masking and so it can be performed even if the opposite ear has already been operated on by stapedectomy.

Since the post-operative functional result is the only accurate reflection of the true cochlear reserve and as the B. C. SWT always predicts the outcome of the ear operated on by stapedectomy in otosclerosis, our B. C. Speech Weber test appears always reflective of the real cochlear reserve. So the best means for the precise evaluation of the true cochlear reserve is only given by B. C. speech audiometry, mainly by our B. C. Speech Weber test.

The only difficulty is to perform this test during the two or three first post-operative days in the patient's room. The B. C. SWT needs a sound proof test cabin, with a tape recorder. For this reason, we are used to perform a B. C. pure tone audiometry every day and the first three days in the patient's room, and if B. C. pure tone testing shows either a B. C. decrease or its disappearance, the patient is immediately tested in a sound proof test room with complete equipment, mainly an audiometer with speech material delivered by tape recorded with dissyllabic word-lists. We believe that transferring the patient recently operated on by stapedectomy to a sound proof equipped test room is less dangerous for the cochlea than to remain doubtful about a questionable B. C. level in pure tone audiometry easily performed in the patient's room. Delay in B. C. Speech audiometry testing prevents the prescription of an efficient therapy in time with high doses of I.V. Cortison, I.V. hypertonic glucose solution, vasodilators, gentle but firm inflations of the middle ear, etc.

These are the only means to perform safe and sure surgery in stapedial otosclerosis, most often associated with a more or less severe cochlear component.

THE EFFECT OF TYMPANIC MEMBRANE PATHOLOGY ON TYMPANOMETRIC PATTERNS

James L. Parkin, M.D., F.A.C.S.
Presbyterian University Hospital
Pittsburgh, Pa.

Tympanometry has become a commonly used technique in the screening of patients with potential ear disease and the diagnostic evaluation of patients with known ear disease. The continuity and mobility of the ossicles, presence of middle ear fluid, degree of middle ear ventilation, pressure of inner ear fluids and the presence of middle ear tumors are factors most commonly referred to as affecting the impedance of sound wave transmission. Assuming the patency of the external auditory canal, the intact tympanic membrane is the reflecting surface for the probe tone.

Pathology of the tympanic membrane is known by audiologists and otologists to affect the tympanometric pattern. They hypercompliant pattern is often attributed to the monomeric or dimeric membrane and the hypocompliant pattern to tympanosclerosis. Little has been written in the medical literature about the predictability of tympanic membrane pathology on tympanometric patterns. This study is an attempted correlation between visualized abnormalities of tympanic membranes and the tympanometric patterns obtained.

Many studies have demonstrated good correlation between careful otoscopy and tympanometry. McCandless and Thomas showed a 96% correlation between otoscopy by an otolaryngologist and tympanometric abnormalities. The correlation is less precise in younger patients where both otoscopy and tympanometry are more difficult. (1) This study like multiple similar studies, does not address the question as to who is correct, the otologist or the audiologist, when the two methods fail to correlate. I would suspect both techniques detect disease the other might miss.

The tympanometry in this study was performed utilizing the Amplaid acoustic impedance bridge utilizing a 220 Hz probe tone. It is recognized that the 660 Hz probe tone is more likely to elicit biphasic responses from thinned tympanic membranes but since the 200 Hz probe tone is more frequently used clinically it was selected for this study. The patients were all examined under a Zeiss operating microscope. Pneumatic otoscopy was carefully performed under microscopy and tympanic membrane photographs were taken.

Tympanometric patterns were classified according to the system proposed by Jerger and Lidin. (2) It was found, however, that patterns were obtained which were not clearly in the Type A, As, Ad, B, or C categories. These examples will be further presented as they are encountered.

Tympanic membrane pathology can generally be categorized into three main groups: absent, perforated, and intact - abnormal (modified from Lidin.) (3) Absent or inaccessible tympanic membranes are associated with atresia or stenosis of the external auditory canal, most commonly encountered in congenital abnormalities. Perforated tympanic membranes result in flat (Type B) patterns if the eustachian tube is closed or failure to obtain a seal if the eustachian tube is patent. The measured volume will often differentiate a flat tympanogram of a noncompliant middle ear system from a perforated tympanic membrane with a closed eustachian tube. Intact abnormal tympanic membranes will be the major subject of this paper.

The pathology of intact-abnormal tympanic membranes has been subdivided into categories indicated in Table 1. It is important to keep in mind that the disease processes

SEGMENTAL RETRACTION	COMBINATION

which result in tympanic membrane pathology also frequently cause middle ear pathology. With an intact pathologic tympanic membrane, the otologist is unable to directly examine the magnitude of middle ear and ossicular involvement. For example, a small amount of tympanosclerosis of

Prices Reduced on Noise-Con Series Volumes

In 1973, the first in a series of national conferences on noise control engineering was held in Washington, DC. The most recent conference, NOISE-CON 79 had the theme "Machinery Noise Control," and was held at Purdue University in West Lafayette, Indiana in the spring of 1979. Proceedings of each conference have been published.

The Institute of Noise Control Engineering has announced that prices have been reduced by 50% on the earlier volumes of the Proceedings of these conferences: NOISE-CON 73 on General Noise Control Engineering, NOISE-CON 75 on Standards, Regulations and Federal Programs for Noise Control and NOISE-CON 77 on Transportation Noise. In addition, an author/subject index to the entire series has been prepared and is available free with orders for any book in the series.

A short description of each volume and ordering information is available in a new flyer which is available from the Institute of Noise Control Engineering. Contact the Institute at P. O. Box 3206, Arlington Branch, Poughkeepsie, NY 12603.

McGill University Schedules Dan Ling

Summer Colloquium on SPEECH, LANGUAGE AND SENSORY PROCESSING IN HEARING-IMPAIRED CHILDREN. August 18-22, 1980. This colloquium directed by Daniel Ling, Ph.D., will provide practical information and strategies that can be directly applied in the remedial treatment of hearing-impaired children. Cost \$150 U.S. or \$175 Cdn. Detailed information will be available on request from March 1, 1980. Contact Ms. Carole Shevloff, School of Human Communication Disorders, McGill University, 1266 Pine Avenue West, Montreal, P.Q. H3G 1A8.

the drumhead may be associated with extensive tympanosclerosis of the ossicles and tympanum.

At times it is difficult to determine if a tympanic membrane perforation has healed with a monomeric membrane. Pneumatic otoscopy under microscopy will allow this diagnosis to be made. The healed monomeric membrane can be visualized under the microscope and motion of that membrane can be assessed.

Case #1 M.M., represents a patient with bilateral tympanic membrane perforations each measuring approximately 1 mm in diameter. In addition, the patient has extensive tympanosclerotic changes of the remainder of both tympanic membranes. Audiometry illustrated in Figure 1 represents bilateral mixed hearing loss. Tympanometry for the right ear is indicated in Figure 2, and for the left ear in Figure 3. Flat

Symposium on Personal Hearing Protection

Sponsored by the Department of Otolaryngology and the Occupational and Environmental Health Unit, University of Toronto, and Mount Sinai Hospital, will be held May 14-15-16th 1980, at the University of Toronto.

Coordinators: P. W. Alberti, University of Toronto, and Edgar Shaw, National Research Council, Ottawa.

For: Audiologists, Design Engineers, Industrial Hygienists, Industrial Safety Personnel, Occupational Nurses, Occupational Physicians, Otolaryngologists, Research Scientists, etc.

Topics include: Biology of Hearing Loss; Risks from sound; Economics; Personal dosimetry; Hearing Protectors: design, safety, effectiveness: laboratory and shop floor; Motivation for use; Hearing Conservation: serial audiometry; Legislation including Ontario Bill 70, and government monitoring; Is it Effective? and MUCH MORE.

More than 20 International experts from Canada, England, France, Germany, Sweden, United States, etc.

Registration fee \$250.00 before April 1st 1980, \$275.00 after April 1st

For further details and registration application contact Mrs. D. McBride, Office of Continuing Medical Education, University of Toronto, Faculty of Medicine, 245 FitzGerald Bldg. Toronto, Ontario, Canada.

Fig. 3

configuration is attributed to the extensive tympanic membrane tympanosclerosis. There is no fluid visualized through either middle ear space. The perforation has healed over with a monomeric membrane on the right side, but is patent on the left side. The measured volume difference in the two ears is an indication of the patency of the tympanic membrane perforation.

Small, patchy tympanosclerosis of the tympanic membrane does not affect the tympanometric pattern if there is a section of normally mobile tympanic membrane interposed between the annulus and the tympanosclerosis and between the long process of the malleus and the tympanosclerosis. It must be remembered, however, that tympanosclerotic changes can also involve the ossicles usually resulting in As type pattern. Extensive tympanic membrane tympanosclerosis as seen in the first case will result in a flat tympanogram even though the tympanum is well ventilated.

Segmental fibrous scarring of the tympanic membrane results in no significant alterations of the tympanometric pattern. However, extensive fibrous scarring and tympanic membrane thickening results in decreased compliance of the conductive system. Figure 4 represents a tympanogram

Fig. 4

obtained from a patient with moderately extensive fibrous scarring of the tympanic membrane. Pneumatic otoscopy indicated a well ventilated middle ear space. Pure tone audiometry was within normal limits.

Segmental retractions of the tympanic membrane can cause some difficulty in the prediction of the tympanometric pattern. Here binocular microscopy with pneumatic otoscopy allows a high degree of accuracy.

Figure 5 represents the audiogram of a 13-year-old girl with

Calls for Papers is Issued Inter-Noise 80

An Announcement and Call for Papers for INTER-NOISE 80 is available from the Institute of Noise Control Engineering. INTER-NOISE 80, the 1980 International Conference on Noise Control Engineering, will be held on 1980 December 8-10 at the Hotel Inter-Continental in Miami, Florida, and will have the theme "Noise Control for the 80's." Papers are being solicited in a number of technical areas, including machinery noise reduction at the source, impulse and impact noise, noise emission measurements, labeling, active noise attenuators, acoustical data banks and noise control in industry.

The meeting is the ninth in a series of conferences which have been held annually since 1972. Deadline for the receipt of abstracts is May 12, 1980.

Copies of the announcement and further information on INTER-NOISE 80 are available from the Institute at P. O. Box 3206, Arlington Branch, Poughkeepsie, NY 12603.

Effect of Tympanic

Cont. from pg. 14

Fig. 5

a long history of recurrent otitis media and bilateral tympanostomies on three occasions. Otoscopy reveals the tympanic membrane which has been segmentalized by bands of fibrous scarring. Large areas of the patients tympanic membranes are deficient in the fibrous layer. These segmental retraction pockets were slightly retracted but were hypermobile with pneumatic otoscopy. The tympanometric patterns indicate hypercompliant systems with negative middle ear pressure. (Figures 6 and 7). This pattern of tym-

Fig. 6

Fig. 7

panogram does not fit well in the classical descriptions and possibly indicates a Type Cd.

The next patient, C. Z., is a 67-year-old female with progressive bilateral decreased hearing and a childhood history of recurrent episodes of otitis media. Her audiogram, Figure 8, represents bilateral sensorineural hearing loss with no

Fig. 8

significant conductive component. Otoscopy indicated tympanic membranes segmentalized by fibrous tissue and areas of monomeric or dimeric membranes. The anterior superior monomer was bulging in the left ear as seen by binocular microscopy. A similar area in the right ear was retracted. Figure 9 and 10 represent they tympanometric patterns seen

Fig. 9

Fig. 10

in these two ears respectively.

The next patient, L. B., also has bilateral segmental retractions. Otoscopy of the left ear indicates a normal appearing pars tensa with a retracted pars tensa, i.e., attic retraction

Use of Minicomputers in Speech and Hearing Research

An intensive five-day course at the introductory level.

Sponsored by:
Northwestern University
Department of Communicative Disorders

August 1980
and
January 1981

This course is designed to provide speech and hearing scientists, neurologists, physiologists, and psychologists with a basic understanding of how minicomputers work and how they are used in various areas of research. The course will cover the basic concepts of computer hardware and software, control of experiments, stimulus synthesis and analysis, data acquisition and reduction, and the elementary techniques involved in interfacing a computer to other laboratory equipment. Each topic will be covered in lectures, with extensive demonstrations of computers and associated laboratory equipment. The lectures will be complemented with small-group laboratory sessions, which will give participants hands-on experience with many of the techniques discussed.

Course Instructors: Fred Wightman, Ph.D. and Israel Raz, Ph.D.
Enrollment Limited.

Address inquiries to Frederic L. Wightman, Auditory Research Laboratory, Northwestern University, 2299 Sheridan Road, Evanston, IL, USA 60201

Prof. Ettore Bocca

PROF. ETTORE BOCCA,

DIRECTOR OF THE ENT UNIVERSITY CLINIC OF MILAN, RECEIVED THE AMPLIFON RESEARCH AND STUDIES CENTRE'S INTERNATIONAL PRIZE FOR 1979, FOR HIS CONTRIBUTION TOWARDS THE FIGHT AGAINST DEAFNESS.

Amplifon Research and Studies Centre's International Prize, the maximum acknowledgement for studies regarding the fight against deafness, has been awarded, for the year 1979, to the Director of the ORL Clinic of the University of Milan, Prof. Ettore Bocca.

The prizegiving ceremony took place on the 20th March at the Press Club in Milan, in the presence of a vast audience of scientists and doctors from all over Italy.

The Prize Committee's motivation emphasized Prof. Bocca's contribution for solving general problems of audiometry and made particular reference to his research on the diagnosis of lesions of the central auditory system.

The prizewinner was presented by Prof. Massimo Del Bo, Director of the Institute of Audiology of Milan University. Prof. Antonio Antonelli, of the ENT Clinic Of Milan University, illustrated the original and intuitive nature of Prof. Bocca's findings, which brought him fame throughout the world.

The President of Amplifon's Research and Studies Centre—Charles Holland—during the course of the ceremony gave an account of the Centre's activities during the past year.

Starting from 1979 the prize, endowed with approx. \$6,000, has been enriched with a further 2,000,000 Lire (approx. \$2,000) which the prizewinner will assign as a scholarship for researches in Audiology to a young student chosen by him.

In this manner Amplifon's CRS intends to link honouring an internationally famous scientist to motivating young doctors at the start of their career towards research.

During the afternoon of the same day a Symposium was held in honour of Prof. Bocca in the Amplifon Research and Studies Centre, on the theme "Audiometry and the Lesions of the Central Auditory System," attended by Audiologists, ENT doctors and Health Authorities from all over Italy.

The previous prizewinners are as follows:

Prof. Tokuro Suzuki (Japan), Prof. Erik Wendenberg (Sweden), Prof. Hallowell Davis (USA), Prof. James Jerger (USA), Prof. Jozef J. Zwislacki (USA), Prof. Suzanne Borel Maisonny (France), Prof. Michele Arslan (Italy), Prof. Aram Glorig (USA).

SENTAC Meeting Announced

The Society for Ear, Nose and Throat Advances in Children (SENTAC) is holding its annual meeting at The Mark at Vail, December 5, 6, and 7, 1980.

This is a call for papers for the annual meeting. Papers should be devoted to new ideas in the fields of audiology, speech pathology, otolaryngology and pediatrics relating to the concept of ear, nose and throat advances in children.

The papers will be of 10 minutes duration and an abstract of 250 words maximum will be required. The closing date for receipt of abstracts is July 15, 1980. Papers submitted for

presentation for SENTAC will be submitted to The International Journal of Pediatric Otolaryngology for consideration for publication.

For Further Information, please contact:

Allan B. Seid, M.D.
Program Chairman, SENTAC
Children's Hospital Medical Center
Elland and Bethesda Avenues
Cincinnati, OH 45229

Effect of Tympanic

Cont. from pg. 17

Small attic retraction pockets are commonly seen. If the pars tensa is normal, these attic retraction pockets have no effect on the tympanometric pattern. Another aspect of segmental retractions to be remembered is that apparent retraction pockets may be adherent to the promontory of ossicles of the middle ear. This fixation of the pocket most commonly occurs to the long process of the incus. This can be assessed by binaural otoscopy. Fixation of the retraction pocket may cause decreased compliance. The right ear of patient C. Z., Figure 10 also had a posterior superior segmental retraction pocket adherent to the long process of the incus.

Inflammation of the tympanic membrane with a ventilated middle ear space can occur in myringitis bullosa and otitis externa. It has been my experience with myringitis bullosa, however, that the majority of these patients also develop middle ear fluid with either bulging or retraction of the tympanic membrane resulting in flat tympanometric patterns.

Otitis externa can cause inflammation of the tympanic membrane with thickening of the membrane and decreased compliance. Patient B. O. had a chronic otitis externa with thickening of the tympanic membrane. Otoscopy indicated normal middle ear ventilation. Pure tone audiometry was within normal limits. Her tympanogram is shown in Figure 13.

Glomus jugulare and glomus tympanicum tumors can impinge upon the tympanic membrane without direct involvement of the tympanic membrane. Patient P. R. is a 68-year-old woman with a large glomus jugular tumor which fills the lower 35 to 40 percent of her ear canal and rests upon the tympanic membrane. However, the superior portion of her tympanic membrane is intact. It appears normal and has good mobility. Her tympanometric pattern, Figure 14, is within normal limits.

The next patient is a 6-year-old child with a congenital cholesteatoma visualized as a whitish mass between the posterior aspect of the tympanic membrane. His tympanic membrane otherwise appeared normal and was mobile. The tympanometric pattern is seen in Figure 15.

G. T. is a 76-year-old female with a large secondary acquired cholesteatoma. Surgery has not been advised because of her age and general medical condition. Cleaning of the cholesteatoma cavity is accomplished every three to four months. Following cleaning, her cholesteatoma is found to extend into the attic. It has destroyed the posterior superior bony canal wall and extends into the posterior tympanum with destruction of the incus, stapes, and a portion of the malleus. The anterior tympanic membrane segment, in the region of the eustachian tube orifice, is intact and mobile; however, this segment represents probably less than 10 percent of the total area encountered by the sound probe. Her tympanogram is indicated in Figure 16.

It must be remembered that many of these pathologies can occur in combination. The otologist can examine well the tympanic membrane with binocular microscopy and pneu-

matic otoscopy; however, he is usually unable to see the middle ear structures, especially the medial ossicles. Their mobility also affects tympanometric patterns. Combination pathologies are more difficult to predict.

SUMMARY:

Tympanic membrane pathology does affect tympanometric patterns. These effects are usually predictable otoscopically if the tympanic membrane is carefully examined under an operating microscope and utilizing pneumatic otoscopy. They are less predictable if a hand held otoscope is the method of examination. Subtle abnormalities such as the bulging or retraction of a healed perforation may be overlooked. It is crucial to remember that diseases resulting in tympanic membrane pathology also cause middle ear abnormalities. The tympanometric pattern is confused by combinations of pathology and may lead to the conclusion reached by Feldman that acoustic impedance is useful in the diagnosis of middle ear disease only when an intact, normal tympanic membrane exists. Scott Reger Honored By West Virginia University

On the occasion of Scott Reger's award of an honorary degree from his alma mater, West Virginia University, the following citation was made.

"Doctor Reger is certainly an uncommon man. His achievements have gained him an enviable international reputation in the field of audiology, acoustics, and otolaryngology. He is certainly in the category of West Virginia University graduates who have gained unusual eminence in their profession."

"Although a modest, humble man, personally, Dr. Reger is auditory mechanism, but one of the true pioneers in the field of auditory measurement. He is considered by many as the first audiologist in the United States and was among the first scientific investigators in this country interested in the quantitative measurement of hearing levels. He has been active in this field since the early 1930's and there are hardly any aspects of auditory phenomena that were not originally investigated by him.

He is blessed with creativity and inventiveness coupled with unique technical knowledge and skills. This has enabled him not only to design, but to construct instruments to measure hearing acuity which at that time were unavailable. For example, he is credited with the design and construction of the first clinically workable model of the Bekesy automatic audiometer available in this country."

"Through Dr. Reger's work on the measurement of the ear, he has gained the respect and admiration of not only his colleagues in the field of hearing science, but in related disciplines as well, such as acoustics and otolaryngology. This recognition is evidenced by his being named an Honorary Fellow of the American Academy of Ophthalmology and Otolaryngology, a Fellow of the Acoustical Society of America, an Associate Fellow of the American Laryngological, Rhinological, and Otolological Society, and the Honors of the American Speech and Hearing Association."

"He has been instrumental in the establishment of firm interdisciplinary communication with the field of otolaryngology."

ology. He often served on the board of examiners of the national boards of the American Academy of Ophthalmology and Otolaryngology."

"He was one of the early scientists to recognize the relation ship between exposure to unduly intense noise and damage to the inner ear of man. He devised instrumentation and clinically useful techniques to detect and measure the extent of this damage. The fruits of this pioneering interest has culminated in recent years in the Federal Government's active role in the protection of the ears of workers in industry from unduly intense noise."

"He received the Bachelor of Arts degree from West Virginia University in 1927 and then took the first two years of the medical school curriculum. In 1929, he went to the University of Iowa as an Eastman Fellow in Psychology of Music. He has remained at the University of Iowa ever since, receiving the Master of Arts degree (1931) and the Doctor of Philosophy (1933). He then joined the faculty of Iowa Medical Center. For many years he was a musician participating in the woodwind section of the University of Iowa faculty orchestra."

"Dr. Reger has been an outstanding contributor and innovator in all facets of the field of audiology and acoustics: researchers, teachers, clinician and administrator. He is truly one of the most respected leaders in his field. As Professor Emeritus of the University of Iowa, he continues to make significant contributions to his profession. The fact that he is a native of West Virginia (Weston) and a graduate of West Virginia University should make us proud to be affiliated with this state and this institution. He has had an exemplary career and would be an outstanding example of true eminence for the student body of West Virginia University to follow."

Corti's Organ proudly Salutes our colleague and friend, Scott Reger, Ph.D., D.Sc.H.C.

ABR Course Announcement

The Kresge Hearing Research Laboratory of the South, LSU Medical Center, New Orleans, Louisiana, will present a Short Course in Auditory Brainstem Response June 13-16, 1980, with an additional, optional practice day on June 17. The course is co-sponsored by the Lions Eye Foundation of Louisiana, the Eye & Ear Institute of Louisiana and LSU Office of Continuing Medical Education and will feature morning lectures on Anatomy, Physiology and Instrumentation as they relate to applied auditory physiology, and afternoon labs with hands-on, practical instruction in ABR. Special concurrent sessions will be available for people with no experience in electrophysiological measurement. Jim Stockare, MD, PhD, from the Department of Neurology, Mayo Clinic, will be the guest lecturer. Participants will have the opportunity to talk with representatives of major equipment manufacturers and to try their product.

The \$400 tuition includes, in addition to an educational opportunity of the finest quality: reduced hotel rates; free evening jazz party, featuring outstanding New Orleans musicians and hors d'oeuvres; free coffee and refreshments throughout the course. Free transportation to and from the airport and between the hotel and course location may be available, courtesy of the Eye & Ear Institute.

The Lions Eye Foundation of Louisiana may once again provide some full tuition scholarships for graduate students, residents, audiologists, etc. Enrollment in the course is limited to 40 paid participants, or 5 workers per available computer. For further information, application forms, and information on applying for scholarships, please contact Course Coordinator, Kresge Hearing Research Laboratory, 1100 Florida Ave., Bldg. 147, New Orleans, LA 70119, or call (504) 947-6641.

Attacking the Ski Slope

Model AE

Problem:
Classic sensorineural hearing loss where speech intelligibility is the primary concern.

Recommendation:
Evaluate Dahlberg's new Model AE, engineered to eliminate low frequency amplification (below 1,000 Hz) with usable gain to 6,100 Hz (37 dB). Model AE has both fitter and user adjust fre-

We invite you to compare the high frequency response of Model AE to any other instrument currently available.

What is the American Auditory Society?

The American Audiology Society was formed in October, 1974. In June, 1978, after a vote by the members of the Society, the name was changed to the American Auditory Society. The following provides basic information regarding the Society.

What Is The Purpose Of The Society?

The primary aims of the Society are to increase knowledge of human hearing, promote conservation of hearing, and foster habilitation and rehabilitation of aurally impaired individuals. To attain these goals, the Society will coordinate and disseminate information, particularly through the holding of regular meetings, and the publishing of reports. Because of the multiple disciplinary nature of the Society's membership (audiology, otolaryngology, deaf education, hearing aid engineering, psychoacoustics, etc.), the Society will provide a formal platform for the interchange of information from allied professional fields.

Who Can Be A Member?

Active membership is open to individuals holding at least a

baccalaureate degree from a recognized academic institution or to an individual who has had the equivalent of an academic degree in scientific experience or in professional experience in the field of audition. Admission to the Society may be granted by the Executive Committee after the candidate has submitted an application with recommendations from two members, and has paid dues for the year in which application is made. Persons wishing to become members must have an interest in human hearing. The Society shall be based primarily within the United States, but there shall be no geographic limitation on membership.

When And Where Will Meetings Take Place?

An annual meeting will be scheduled to take place either the day before or after annual meetings of other professional groups, such as the American Academy of Otolaryngology (AAO), and the American Speech and Hearing Association (ASHA) and the Acoustical Society of America (ASA).

Will There Be A Journal?

The Society publishes *Ear and Hearing*. *Ear and Hearing* has a clinical format and is issued bi-monthly (6 issues per year). In addition, "*Corti's Organ*" is published on a quarterly basis. *Corti's Organ* is an informal publication and the purpose is to keep members aware of Society activities and other notable events.

How Much Are Dues?

Annual dues are \$29.00. Because the Society will not concern itself with political issues, such as licensure, certification, etc., dues will remain reasonable. All members receive both of the publications as part of their dues.

How Does One Join The Society?

To become a member submit an application, with an endorsement from two active members, to the Secretary/Treasurer. For more information write: Ross J. Roeser, Ph.D., Secretary/Treasurer, American Auditory Society, 1966 Inwood Road, Dallas, TX 75235.

Presidents of AAS

Aram Glorig

W. Dixon Ward

Geary McCandless

Samuel F. Lybarger

Laura Wilber

Ralph Naunton (President Elect)

Special Membership Offer

The membership qualifications for AAS include a minimum of a Bachelor's degree or the equivalent in experience and signatures of two active members of the Society. Until July 1, 1980, applications will be accepted without accompanying signatures for applicants who do not know the names of two active members if they are sent on the form below. The secretary/treasurer's office will obtain the necessary signatures from two active members.

The AAS Tours to the International Audiology Congress

AAS's European counterpart, the International Audiology Society will hold its XV Congress in Krakow in September 1980. To make it reasonable and congenial for AAS members to attend, group tours are being planned for members, their families and friends.

Among the AAS members who will present papers in Krakow will be Ralph Naunton, Aram Glorig, LaVonne Bergstrom and Marion Downs. Phillip Peltzman will also be on the program. There will be three plenary sessions:

(1) Evaluation of Auditory Function after Surgical Procedures, (2) Etiologic Factors in Sensorineural Hearing Loss, and (3) Paedodaudiology. In addition, contributed papers will be presented.

Two options are being planned for the tour: one a seven-day trip to the Krakow Congress and back; the other an additional week's tour of Vienna and Budapest.

TOUR I—7 days. Air Fare from New York: \$695.00

Departure from New York—August 31

Return New York—September 7

August 31

New York—Evening departure for Warsaw on Pan Am.

September 1

Warsaw and Airport meeting and transfer to hotel. Cocktail party and dinner. Overnight.

September 2

Warsaw/Cracow. Breakfast. Leave Warsaw after breakfast by bus. Stop for lunch at Czestochowa and visit to Black Madonna Shrine.

September 2-6

On your own in Cracow.

September 6

2:00 P.M. leave by bus for Warsaw. Overnight.

September 7

Morning sightseeing. Take Pan Am for New York at noon.

TOUR II—14 days. \$1450.00

FOUR COUNTRY TOUR

POLAND, HUNGARY, AUSTRIA, CZECHOSLOVAKIA

Departure from New York: August 31

Return New York: September 13

1st Day: August 31

New York—evening departure for Warsaw via Pan Am flight.

2nd Day: September 1

Warsaw—Airport meeting and transfer to your hotel. In the evening welcome cocktail party. Dinner and overnight.

3rd Day: September 2

Warsaw/Cracow—Leave Warsaw after breakfast for Cracow. En route stop in Czestochowa where lunch and brief visit to the Monastery with its famous Black Madonna Shrine. Continue to Cracow. Dinner and overnight.

4th Day thru 8th Day: September 3 thru 6

CRACOW - CONVENTION

8th Day: September 6

Cracow/Zakopane. You will continue your tour after 2 PM. Leave Cracow for Zakopane in the Tatra Mountains. Free time till evening then entertainment by the Highlander Folk Group. Dinner and overnight.

9th Day: September 7

Zakopane/Budapest. Morning departure southward to Czechoslovakia across the Tatra Mountains to Hungary. Dinner and overnight.

10th Day: September 8

Budapest—Morning sightseeing tour of Budapest. Visit: The Citadel, St. Matthew Church, Parliament building. Afternoon free. In the evening dinner with folkloric gypsy entertainment. Overnight.

11th Day: September 9

Budapest/Vienna. Drive through Gyor and Nickelsdorf to Vienna. Lunch en route. Dinner and overnight in Vienna.

12th Day: September 10

Vienna—In the morning city sightseeing. Visit Schonbrunn Palace, Hofburg and St. Stephen's Cathedral. Afternoon free. In the evening tour and visit to Grinzing (drinks not included).

13th Day: September 11

Vienna/Prague. Morning departure for Prague, the capital of Czechoslovakia. Lunch en route. Overnight in Prague.

14th Day: September 12

Prague. City sightseeing in the morning. Visit among other sights the Waldstein Palace Museum and National Museum. In the afternoon time at leisure. Dinner and overnight in Prague.

15th Day: September 13

Prague/New York. After breakfast depart for the airport for your flight home. Arriving the same day.

TOUR FEATURES

ACCOMMODATIONS:

Hotels: Accommodations with private bath or shower. Hotel service charges and taxes are included.

The Davis name is known even in the wilderness!

They just aren't teaching people to spell correctly anymore!

Meals: Three meals daily in Poland. Seven breakfasts, three lunches, four dinners (in remaining countries as per itinerary.)
Transportation and Sightseeing: Transfers between airport and hotels; tips to porters for baggage and hotel. All sightseeing and excursions, by deluxe motorcoach, described. Entrance fees where they apply. English speaking guides.

TOTAL: LAND/AIR

\$1,450.00

Per Person/DbI

Single Supplement \$145.00

Air Fares: GIT/APEX-NYC/WAW/PRG/NYC subject to change in event of a fuel increase.

Russia Gets the Sack from AAS

The 2-week AAS tour to the International Audiology Congress in Krakow had planned to take in parts of Russia after the Congress ends. However, with the current national feeling about Russia's invasion of Afghanistan, AAS withdraws any notion of visiting in the Russian sector. Instead, more time will be spent touring beautiful Vienna and exotic Budapest.

The two options for group tours to the Congress are outlined on this page. Please note that one does not have to

be a member of AAS or of the International Audiology Society in order to join the tour. It is open to anyone interested in joining either group, for the Congress alone or for the longer two-week tour.

For those going only to the Congress for the week's stay the price includes airfare alone, plus the two night's stay and dinner in Warsaw, the bus trips to Krakow and back and lunch en route. After arrival in Krakow participants in the Congress must make their own arrangements for lodgings and meals.

CALENDAR OF EVENTS

MAY
9-10

ENG INTERPRETATION, Washington, D.C. 12 hours Category 1 credit for Physician's Award, AMA. The course is designed to aid physicians and audiologists using electronystagmography in the accurate interpretation of ENG findings. Fee: \$200.00. Contact: Marion Servos, ICS, Inc., 520 Interstate Road, Addison, IL, 312-543-6200.

10-11

ADVANCED ELECTRONYSTAGMOGRAPHY COURSE, Memphis, Tennessee. Contact: Course Coordinator, Life-Tech Instruments.

10-12

AUDITORY EVOKED POTENTIALS, Houston, Texas. Contact: Alfred C. Coats, 6565 Bertner Avenue, Houston, TX 77030.

28-30

DIAGNOSIS & REMEDIATION OF CENTRAL AUDITORY DYSFUNCTION IN CHILDREN, University of Cincinnati, Ohio. Contact: Dorothy H. Air, University of Cincinnati Medical Center, Audiology and Speech Pathology Division, Cincinnati, OH, 513-872-4241.

JUNE
4-6

TRAINING COURSE FOR AUDIOMETRIC TECHNIQUES IN INDUSTRY, Fullerton, CA. 18 hours RN credit. Fee: \$200.00. Contact: Max Nelson, Ph.D., Industrial Audiology Institute, 1530 N. Sycamore Ave., Fullerton, CA 92631, 714-879-4265.

9-20

TEACHING LANGUAGE TO DEAF CHILDREN, St. Louis, Missouri. Contact: George Fellendorf, Box 57241, Washington, D. C. 20037, 703-524-5600.

21-25

REHABILITATION THROUGH AMPLIFICATION WORKSHOP, Chicago, IL. Sponsor: American Hearing Research Foundation, AMA Category I credit. Contact: Jack D. Clemis, M.D., Program Chairman, American Hearing Research Foundation, 555 East Washington Street, Suite 2105, Chicago, Illinois 60602. Phone: 312-726-9670.

24-28

1980 INTERNATIONAL CONVENTION, Houston, TX. Sponsor: Alexander Graham Bell Association for the Deaf. Contact: A.G.B. Assn. for the Deaf, 202-337-5220.

27-28

14TH WORLD CONGRESS OF REHABILITATION INTERNATIONAL, Winnipeg, Canada.

27-28

CLINICAL ELECTRONYSTAGMOGRAPHY, Chicago, IL. 12 hours Category I credit for Physician's Award, AMA. These are parallel sessions in the practical aspects for technicians and neuro-otologic applications for physicians and experienced audiologists. Fee: \$200.00. Contact: Marion Servos, ICS, Inc., 520 Interstate Road, Addison, IL, 312-543-6200.

JULY

9-16

TENTH INTERNATIONAL CONGRESS ON ACOUSTICS, Sydney, Australia. The Congress will explore the future of acoustics in its many aspects. Contact: 101CA Executive Committee, 35-43 Clarence St., Sydney, NSW2000, Australia.

14-18

28TH ANNUAL OCCUPATIONAL HEARING LOSS INSTITUTE, University of Maine at Orono, Bangor, ME. 27 credits in PRA Category I of AMA Physician's Award. CAOHC accreditation. This course covers the total field of conservation of hearing to enable the professional to implement, administer and advise in effective hearing conservation. Fee: \$300.00. Contact: U.M.O. Coordinator, 1721 Pine St., Philadelphia, PA 19103, 215-735-0205.

AUGUST

4-7

18TH CONGRESS OF THE INTERNATIONAL ASSN. OF LOGOPEDICS AND PHONIATRICES, Washington, D. C. Contact: Frances J. Johnston, Ph.D., IALP Congress, 10801 Rockville Pike, Rockville, MD 20852, 301-897-5600.

4-8

INTERNATIONAL CONGRESS OF EDUCATION OF THE DEAF, Hamburg, West Germany. Contact: S. Richard Silverman, Ph.D., Central Institute for the Deaf, 818 S. Euclid, St. Louis, MO 63110.

SEPTEMBER

2-6

XV INTERNATIONAL CONGRESS OF AUDIOLOGY, Krakow, Poland. Contact: Dr. Andrzej R. Halama, Kopernika 23a, 31-501, Krakow, Poland.

16-20

7TH ANNUAL DOREEN POLLACK ACOUPEDIC WORKSHOP, Denver, CO. Contact: Listen Foundation, 2525 S. Downing, Denver, CO 80210.

NOVEMBER

20

ANNUAL MEETING OF THE AMERICAN AUDITORY SOCIETY, Detroit, Michigan. Contact: A. Bruce Graham, Ph.D., Henry Ford Hospital, Detroit, Michigan.

21-24

AMERICAN SPEECH-LANGUAGE-HEARING ASSOCIATION, Detroit, Michigan. Contact: Conventions ASHA, 301-897-5700.

DECEMBER

3-5

SOCIETY FOR EAR, NOST AND THROAT ADVANCES IN CHILDREN, The Mark, Vail Colorado (See page 17).

1981

JUNE

21-27

12TH WORLD CONGRESS OF OTO-RHINO-LARYNGOLOGY, Budapest, Hungary. Written to: Professor Dr. L. Surjan, P.O.B. 112, Budapest, Hungary, H-1389.

In All The Years of Hearing Instrumentation There Has Never Been an Engineering Achievement Quite Like The Widex A8+*

Years of research and development have culminated in a major breakthrough in postauricular hearing aid design.

Among the many features of the A8+ is an optimally-smooth frequency response, without the peaks and valleys usually associated with ear-level instruments. This is accomplished by a new technique of acoustic filtering developed in the Widex laboratories.

*Models A8+T and A9+T feature a high-efficiency induction pickup coil for effective loop-system use and enhanced telephone listening.

*Models A8+H and A9+H include a user-adjusted Bass Cut Switch which provides selection of two response contours.

The Electronic Tone Control in the A8+ provides bass-cutoff limits of 100 to 800 Hz, with no attenuation of those frequencies above 1200 Hz. This makes possible the fitting of a wide variety of audiometric configurations, ranging from "flat" losses to "Ski-slope" impairments.

New: Gain Limiter Control enables the Hearing Aid Consultant to pre-set the maximum available gain. Allows the patient with a mild loss to utilize the full range of the volume control. Also secures against excessive gain which might otherwise cause discomfort or acoustic feedback.

Additional Features: Continuously adjustable compression and output controls; numbered volume control, dual wind-shielded inlet ports; economical battery service.

Response characteristic of a typical wide range ear-level hearing aid. Note the peaks and valleys which can degrade auditory perception.

Response characteristic of the Widex A8+. The smooth, gradually rising curve simulates the response of the unaided normal ear, resulting in unsurpassed fidelity and listening comfort.

Low-frequency response is continuously adjustable, with cutoff limits of 100 to 800 Hz. Only those frequencies below 1200 Hz are attenuated, thereby preserving the high-frequency components of music and speech.

Directional Version Also Available: The Widex A9+ combines all the features of the A8+ with directional performance featuring an improved front/rear selectivity ratio.

Full-Color, Sixteen Page Introductory Brochure: Write or phone for your free copy of a comprehensive, descriptive manual on the A8+ and A9+ series.

CORTI'S ORGAN

The Official House Organ of the American Auditory Society

Vol. 6, No. 2

Spring/Summer 1981

AAS Annual Meeting to be a Blast

The 1981 Annual Meeting of the American Auditory Society will be held in New Orleans, La., on September 21, 1981 in conjunction with the American Academy of Otolaryngology-Head and Neck Surgery. The meeting will take place at the Marriot Hotel in The La Galerie room, No. 3, on the second floor. The theme for this year's program is Surgical and Prosthetic Management in Auditory Rehabilitation and will include a full day's presentation of papers and extend into the evening hours with social events. Featured in this year's program are:

Scientific Papers:

Paul Ward, M.D. — will present the 1981 Carhart Memorial Lecture entitled "Research in Communicative Disorders: A Projection for the Next Decade."

Charles I. Berlin, Ph.D. — Auditory Brainstem Responses

Jack Pulec, M.D. — The Management of Tinnitus

William House, M.D. — Cochlear Implants

Ted Bailey, M.D. — Hearing Aid Dispensing from the Otolaryngologist's Office

Selected Submitted Papers

Social Events:

6:30-8:30 p.m. A scenic river boat tour of the New Orleans historic river front with complimentary hors d'oeuvres.

9:00-? Dinner at the internationally famous Commander's Palace Restaurant with a real-live Cajun comedian to enliven the evening.

A pre-registration form is on page 20.

XVI International Audiology Congress To Meet In Finland

Helsinki, Finland will be the site of the 1982 Audiology Congress May 23-27. Two Americans, Jo Zwislocki and Fran Catlin, will be moderators of two of the Round Table sessions of the Congress. Zwislocki will present a panel on "Cochlear Mechanics", and Catlin presides over "Evaluation of Hearing and Hearing Handicap".

Papers are accepted on any audiological topic for the general sessions. Submittals and information requests go to:

XVI International Congress of Audiology
Secretary-General Dr. Tapani Jauhainen
Department of Otolaryngology
Helsinki University Central Hospital
Haartmaninkatu 4 E
SF 00290 Helsinki 29
Finland

Dr. Tauna Palva, well known to American otolaryngologists, is president of the organizing committee of the Congress. He promises lavish entertainment in the historic city of Helsinki.

A pre-Congress symposium will be held at Goteborg, Sweden on May 20-21, organized by Dr. Gunnar Liden. One day will be devoted to "Paedo-audiology" and the other to "Impedance Audiometry", with special emphasis on its use in otologic surgery. Dr. Liden's address is: Goteborgs Universitet, Audiologiska avd., Oronklinken, Sahlgrenska sjukhuset, 413 45 Goteborg, Sweden.

The 1984 Congress is planned for Santa Barbara, California, with Sandy Gerber as the president of the organizing committee. This will only be the second time the Congress has been held in the U. S.

The program of the Congress and pre-symposium is as follows:

Pre-Congress Meeting: Goteborg, Sweden
Thursday, May 20

Problems in Paedo-Audiology

Friday, May 21

Impedance Audiometry (Emphasis: Otologic Surgery)

XVI International Congress of Audiology, May 1982

The President's Message

Clinical Research in the Health
Sciences: A Collaborative Venture

It is now far more years than I care to count up since, as a relatively newly graduated physician from the University of London, I first developed what was to prove to be a life-long interest in the problems of hearing and hearing impairment. I can name the day (and almost the hour of the day) when it all started. I had made the decision to enter a residency training program in otolaryngology and on my first day in the program my new chief told me "Nauton, we want you to revive the Deafness Clinic." (The surname as a form of address is an interesting English custom; it keeps those subordinates in place.) The Deafness Clinic at University College Hospital in London had been started a few years prior to the outbreak of World War II by Dr. Phyllis Tookey Kerridge, but was brought to a halt first by the outbreak of World War II and secondly by the untimely death of Dr. Kerridge. The Clinic was unique in concept, but also in possessing a remarkably efficient and still strikingly enormous sound-treated room the size of a small house.

My reactions to my chief's urging to revive the clinic were three-fold: first, I was surprised to find that anyone who scarcely knew the front from the back of a hearing aid would be asked to assume such a responsibility; secondly, I changed the name of the Clinic to the Hearing Clinic; and thirdly, I immediately set out to establish rapport with the Phonetics Department of the University College, University of London, where, I knew, there were basic scientists interested in the physiology of speech and of hearing and in the study of hearing impairment and its alleviation. My new colleagues in the Phonetics Department were Dr. Dennis Fry and Dr. Peter Denes (the latter now at Bell Labs). Here I ask your indulgence as, for the first time in print, I express my appreciation to Dennis Fry and Peter Denes for their support and encouragement, as I began to follow in the footsteps of Phyllis Tookey Kerridge.

After that first start I went on to establish liaison with other physicists and electronic engineer investigators, with speech therapists, with educators of the deaf, and with the hearing aid industry; at the same time, my training in otolaryngology continued.

Since the early days of the Hearing Clinic in London, my

Pres. Ralph Naunton

experience has included several years as a Scientific Officer with the Medical Research Council of England (spending money from the Privy Purse), a year at the Central Institute for the Deaf in St. Louis, and many years spent at the University of Chicago in the Department of Otolaryngology. In

Editorial

The Joint Committee On Infant Hearing Is Alive and Well

Spurred on by its excellent Chairperson, Dr. Martha Rubin, the Joint Committee on Infant Hearing met April 12 and 13 at the Lexington School for the Deaf. Representatives were present from ASHA, from the Academy of Pediatrics, the Academy of Otolaryngology and the Nurses' Association. The agenda included an up-dating of methods for identifying congenital hearing loss at birth and later.

The Joint Committee will issue its 1981 statement shortly, covering the High Risk Register, BSER and behavioral tests in the identification of deafness at birth. Management of infants was also covered at the meeting.

This Committee has been an outstanding example of cooperation between Societies in achieving common goals. The merging of disciplines bring strength and vigor to the promotion of early identification, as well as giving it increased credibility. How about Joint Committees for other objectives? Should there be Joint Committees for Hearing Aids, for Noise-Induced Loss problems, for collection of psycho-acoustic information, for management of Hearing Loss? Hardly an area exists that would not benefit from the careful scrutiny of several related disciplines.

Can someone come up with a good list?

Meet The Candidates for AAS Executive Committee Election

In August of this year an election will be held to replace seven members of the Executive Committee of the American Auditory Society. In this issue of *Corti's Organ* we have asked each candidate nominated for the office to provide the Membership of the Society with some basic bibliographic information, and to provide their thoughts regarding the future direction of the Society.

LaVonne Bergerman, M.D., F.A.C.S., F.R.C.S., (1957, University of Minnesota), Professor of Surgery, Department of Surgery, Division of Head and Neck, 32-34 Rehabilitation Center, Los Angeles, California 90024.

The American Auditory Society is nearly unique in being an effective multidisciplinary professional organization. It has a fine journal which has been published since 1975 and it also has a useful, readable newsletter.

With this fine record of interest in the functions and malfunctions of the auditory system, it is amazing that less than 10% of the published papers have as even one author an otolaryngologist or other medical specialist. (These figures are based on 26 back issues strewn around my office — incomplete and unscientific!) The physician members of the society are not contributing to the journal, at least — mea culpa! How can the society encourage more participation of its otology segment? Certainly establishing a section for New Developments in Otology in our publication should help. I believe there is more that the AAS or its executive committee could do to round out this aspect of our scientific endeavors.

Daniel L. Bode, Ph.D. (1966, Speech and Hearing Science, Michigan University), Director of Research and Development, Hearing Rehabilitation Research Center, House Ear Institute, 256 South Lake Street, Los Angeles, California 90057.

The American Auditory Society continues to represent the best interests of a variety of specialists in audition, particu-

Letter to the Editor

Dear Editor:

I want to congratulate you and Ross on your editorial in *Corti's Organ*. It is a clear and reasoned statement, with which I agree entirely. You mention the effect upon quality of audiological services when an otolaryngologist tries to also be an audiologist. There is another side to that analysis which is equally pertinent. What happens to the quality of medical care provided by that otolaryngologist when he or she tries to also be the audiologist?

I count as personal friends some of the Europeans mentioned in your editorial. These are individuals whom I respect and whose professional contributions have been prodigious. Nonetheless, as I have said to them on many occasions, the American model of non-physician audiologist makes more sense in terms of its broad utility and application.

I will be mailing some of them a copy of your editorial and also this letter. I'm sure we will be hearing from them.

Keep up the good work.

Sincerely,
David P. Goldstein, Ph.D.
Professor of Audiology

larly those of us who are students of broad areas of study and of integration of knowledge. The Society is the one major organization wherein divisions among professional, scientific, and scholarly interests in hearing and hearing disorders are minimized. The essence of the word "colleague" seems to gain significant emphasis within the organization, both in the scope and style of published manuscripts and in the spirit of comradeship which is evident in the context of formal meetings. The recipients of the Carhart Award continue to be persons who represent the best models of our varied fields and who speak to the communality of the membership. The future of the Society and its individual members is enhanced immensely by these attitudes of community, of attention to issues influencing a wide range of individual and collective interests, and of encouraging a free, yet disciplined, exchange of information, opinions and philosophies.

Sanford E. Gerber, Ph.D., (1962 University of Southern California), Professor of Audiology, Chairman, Department of Speech, University of California, Santa Barbara, California 93106.

I view the American Auditory Society as an interest society as distinguished from a professional society. Therefore, we must continue to encourage participation from all those who ascribe to the society's aims as stated in the by-laws. Similarly, as an interest society, we should stay aloof from sectarian professional concerns except insofar as we foster the understanding of audition and auditory disorders.

A. Bruce Graham, Ph.D., (1953, Northwestern University), Chief, Division of Audiology, Speech and Language Pathology at Henry Ford Hospital, 2799 West Grand Boulevard, Detroit, Michigan 48202.

I consider myself fortunate to have been involved with some of the early planning sessions concerning the American Auditory Society. At the outset I made it quite clear how great I thought the opportunity would be to share the thinking of the many disciplines involved with the hearing impaired. If one is truly concerned with the welfare of these patients, one needs to look at the current otolaryngologic trends in diagnosis and medical or surgical management. From the audiologists come testing techniques and plans for non-medical or surgical habilitation or rehabilitation. New developments in testing or amplification equipment come from the manufacturer. The most effective educational approaches using these tools and the evidence at hand is the province of the educator of the hearing impaired. Each of these specialists has much to offer. There are many professional organizations geared to specific areas of research, but here in the American Auditory Society is an opportunity for genuine sharing of ideas to the benefit of this hearing impaired population.

(Continued on p. 3)

**AAS ANNUAL MEETING
SEPTEMBER 21st**

Meet The Candidates (Cont. from p. 2)

Earl R. Harford, Ph.D. (1958, Northwestern University), Professor of Otolaryngology, Director of Audiology, University of Minnesota Medical School and Director of Audiology Clinic, University Hospitals Outpatient Department, Audiology Clinic Box 283, Mayo Building, University of Minnesota Medical School, Minneapolis, Minnesota 55455.

The basic objectives of the American Auditory Society are to stimulate an increase in knowledge and understanding of the auditory process, to promote conservation of hearing, and to foster habilitation and rehabilitation of persons with hearing impairment. Primary among various vehicles to accomplish this objective is the dissemination of information through podium presentations and publications. The Society has not veered from this course the past six years since its founding in October 1974. There have been efforts by other groups and forces to enlist the formal declaration of support from AAS in political and semi-political issues, but the leadership of the Society rejected such maneuvers.

The strength of AAS lies in the fact that it is essentially an open organization that welcomes anyone who has a sincere interest in the objectives of the Society. The membership is diverse and the pace of the Society is relaxed and congenial. Those who attend the annual meetings can attest to the harmonious atmosphere and the sincerity of the members to support the Society. During the past 18 months the Journal of the American Auditory Society got a new name. (*Ear and Hearing*), a new cover, format and Editor (Ross Roeser). Many members and associates responded to the call to support the journal. By all indicators, *Ear and Hearing* has potential to become one of the major periodicals for hearing health professionals in the coming years. Audiologists, in particular, have been searching, consciously or subconsciously, for many years for an effective publication for the

dissemination of their research, clinical experiences and ideas. *Ear and Hearing* is a natural vehicle to accommodate this need.

As I look into my crystal ball for some enlightenment on the future of AAS, I see productive, exciting and interesting years ahead for this young organization. The AAS can and will meet the needs of many hearing health professionals as a forum for their interests. It must not lose sight of its primary aims and continue to avoid the temptations to indulge in professional politics and non-scientific and non-educational missions. Welcome to all those who can support and maintain the objectives of AAS.

Susanne Kos, M.A. (1975, North Texas State University), Dispensing audiologist, Metroplex Hearing Aid Centers, Inc., Medical Plaza Hearing Aid Dispensary, 801 Road to Six Flags W. #134, Arlington, Texas 76012.

The success of the American Auditory Society has been evidenced recently by the significant increase in members of varying disciplines. This demonstration of a common interest in human hearing will foster, we trust, an ever-widening marketplace for more sophisticated refinements of existing rehabilitative capabilities. By fruitful exchange of information gathered from experiment and experience, we hope to further penetrate the barriers which presently stifle our efforts to fully comprehend the auditory system and our attempts to compensate for its abnormalities.

To this end the official journal of the society has been renamed *Ear and Hearing* to reflect our shared endeavors. The metamorphosis of this compilation of writings has transformed rather pedantic and esoteric readings into a format for prevailing, clinically applicable material. Single issues are now even devoted to special topics for a current

collection of works from authors, renowned and novice alike, providing latest coverage with ready reference.

It would seem with such enthusiasm engendered by the ever-increasing membership and the laudatory contributions of recent data to the society's literature that we cannot fail to attract more and more of those from divergent professions who view the same objective from their respective vantage points. We should expect a prosperous future from such a practical alliance.

E. Robert Libby, O.D. (1948, Pennsylvania College of Optometry), President of Associated Hearing Instruments, Inc., 6796 Market St., Upper Darby, Pennsylvania 19082.

The hearing health care field is vibrating with excitement. Change is occurring constantly and rapidly. The field is undergoing greater changes than in many medical areas.

As hearing health care becomes more important to the well being of the public we face new challenges, new incentives and new goals to meet these increasing and changing demands. The American Auditory Society will and should be in the vanguard of these changes creating new areas of cooperation and progress.

I would be proud to be closely involved with this distinguished professional organization consisting of high quality specialists interacting in an area of close cooperation helping to shape and reshape the hearing health field.

(Continued on p. 4)

1. COMPACT SIZE

The Maico Series G117 is a small aid with great performance range. Some small, cosmetically attractive aids have limitations in either output or gain. The Series G117, however, provides 53 dB peak gain, and 124 dB peak power output (SSPL90).

A numbered volume control, plenty of battery life, an on-off switch, and wide, high frequency bandwidth... the Maico Series G117 is a hearing instrument designed to effectively serve the needs of a significant segment of the hearing impaired population.

2. UNUSUAL THINNESS

The Maico Series G117 is only .295" thick. This is particularly desirable when fitting the person whose ears are close to the head and who wears glasses.

3. TWO SPECIALLY CONSTRUCTED EARHOOKS

An Open Response (OR) earhook is designed to be used in open (unoccluded) earmold fittings. It tends to reduce the potential for acoustic feedback in tubing type fittings.

Continuous line shows in situ response (KEMAR) of Series G117 using Insertion Response (IR) earhook with occluded mold; dashed line is estimate of actual amount of amplification at eardrum (insertion response).

An Insertion Response (IR) earhook is intended for use with closed (occluded) earmolds. It produces a smooth, slightly rising response at the eardrum, instead of a dip, by overcoming the amplitude loss caused by

the full earmold. (As is well known, the ear itself produces amplification at 2700-3000 Hz because of ear canal resonance and pinna diffraction effects. But the presence of a full, closed mold in the ear canal removes this natural amplification and causes a 15-20 dB loss.)

4. TWO TRIMMER CONTROLS

Despite its small size, two concealed adjustment controls provide a wide range of performance adjustability. The Power Output (HF average

SSPL90) can be reduced from 117 dB to 100 dB SPL independent of gain, and the Low Frequency control reduces gain 15 dB at 500 Hz.

5. ULTRACARDIOID DIRECTIONAL PERFORMANCE

Some research studies suggest the ultracardioid response is twice as effective in rejecting signals from the rear hemisphere when compared to aids using conventional directional microphones. The Series G117 has one of the best front (0°) to rear (180°) response separations, especially in the higher frequencies, and maintains separation even in open (tubing type) earmold fittings.

Illustration shows that separation between front (0°) and rear (180°) response of Series G117 is broadly distributed across frequency, extending into the higher frequencies (HA 2 coupler, 60 dB input).

Meet The Candidates (Cont. from p. 3)

William L. Meyerhoff, M.D., Ph.D. (1966 Northwestern University; 1979, University of Minnesota) Associate Professor, Chief, Department of Otolaryngology, University of Minnesota, Minneapolis, Minnesota.

The American Auditory Society is one of the few official organizations supplying the route for dissemination of information between members of disciplines who are interested in auditory problems. Through this mechanism of interdisciplinary interaction the goal of improved patient care is being achieved. In the future, the American Auditory Society must continue this charge and aggressively bring about an awareness of its existence and goals among those individuals who are clinically or scientifically interested in audition. In addition, it may be conceivable in the future, to use the treasury of the American Auditory Society to supply small seed monies to young individuals beginning auditory research.

James A. Nunley, B.S. (1958, Oklahoma State University), Director of Engineering Audiotone, 2422 West Holly, P. O. Box 2905, Phoenix, Arizona 85062.

"When this Society was founded, I personally was very excited. There was, and still is, a great need for exchange of ideas and information between the various disciplines in our field. I think the Society, through its meetings and publications, has provided a good forum for this interchange. I would hope the Society would continue these efforts. I think the Society is in a position to, not only encourage, but originate joint projects between the various disciplines. Joint efforts to solve problems could have some very positive results. Sometimes it is amazing what clever solutions can be found to problems when people with different perspectives take a new look at that problem. With admiration for past accomplishments and great hope for future success of the Society, I would be honored to be elected and serve on its Executive Committee."

W. Dixon Ward, Ph.D. (1953 Harvard University), Professor, U. of Minnesota (Depts. of Communication Disorders, Otolaryngology, Environmental Health, Psychology), 2630 University Ave. SE Minneapolis Minnesota 55414.

To the best of my ability, I support the aims of the Society as stated in our by-laws: to increase knowledge about audition, to promote conservation of hearing, and to develop procedures and devices to assist the hearing impaired. In general, I oppose involvement of the Society in political issues, particularly those that have nothing to do with audition, but including arguments over territorial claims (only the incompetent want monopoly).

(Continued on p. 20)

L. Deno Reed, Sc.D. (1959, The Johns Hopkins University), Director, Office of Research and Demonstrations, National Institute of Handicapped Research, Switzer Building, Room 3426, 400 Maryland Avenue, SW., Washington, D. C. 20202.

As a charter member of the American Auditory Society, I have supported the aims of the Society. During my thirty years of professional service I have continually participated in the increase of knowledge, understanding of the auditory process, promotion of hearing conservation, fostering of rehabilitation, information of program development, and dissemination of information both nationally and internationally. As a member of the Executive Committee I would continue my active support in all of the purposes of the Society.

IN MEMORY

Anupum I. Master, 42, director of audiology at Mercy Hospital and Medical Center in Chicago, died at the hospital April 13th after a heart attack.

Born in India, Mr. Master helped to establish the audiology department as the hospital's first audiologist in 1969.

He is survived by his wife, Kunjlata; his son, Viraj; his daughter, Anuja; his parents, the Rev. and Mrs. Ithiel V. Master; and his sister Suvasini McCormick.

Mercy Hospital and Medical Center, chartered in 1852, is a member of the Metro Six hospital group affiliated with the University of Illinois College of Medicine.

Abstracts and Summaries from 1980 Annual Meeting (Continued from Winter/Spring Issue)

An Evaluation Of Victoreen's MCL Hypothesis

LOREN L. WEBB, Ph.D.
Department of Speech Pathology and Audiology
Western Washington University
Bellingham, Washington

ABSTRACT:

The otometric procedure for prescribing hearing aids, as outlined by Victoreen, is based on MCL values to a damped wave signal (DWS). No independent laboratory has investigated the validity of Victoreen's MCL hypothesis. We evaluated this hypothesis by measuring MCL's in normals and successful hearing aid wearers with both the DWS and N-B noise.

Our results support the Victoreen hypothesis; however, because of high intersubject variability, the practicality of Victoreen's method is questioned.

Clinical Application of The Feasibility Scale For Predicting Hearing Aid Use With Older Subjects

RALPH R. RUPP, Ph.D.
The University of Michigan
Ann Arbor, Michigan 48109

The prediction for individual adjustment to wearable amplification is one that should be made by the audiologist following the clinical hearing aid evaluation and the following orientation period. The clinical audiologist can collect subjective information, along with objective data on an older individual which can provide a strong provisional estimate as to ultimate daily usefulness of the subject's hearing aid.

The purpose of this paper is to present a clinical view of a feasibility scale for predicting the probable use of a personal hearing aid with an older individual. The Feasibility Scale for Predicting Hearing Aid Use (FSPHAU) amasses findings on eleven prognostic factors which cumulatively indicate the likelihood of successful amplification for the older person.

The eleven prognostic areas include the following:

1. Motivation and manner of referral to professional audiologic services,
2. Self assessment of the subject's communicative difficulties in reviewing information,
3. Verbalization by the individual as to "fault" for the hearing difficulties,
4. Extent of the hearing loss and understanding difficulties, without amplification and then with amplification,
5. Informal verbalizations about the hearing aid during the hearing aid evaluation,
6. Indication of client's general state of interaction, adaptability and flexibility,
7. Age of the client,
8. Finger and hand dexterity and mobility of the patient,
9. Visual ability of the patient,
10. Financial resources, and
11. The presence of a significant other person to assist the client in the total rehabilitation program.

The most positive prognosis that the patient will become successful hearing aid user is based on the eleven factors just listed. The potentially successful hearing candidate might be described in the following way. He is about 65 years of age, is highly motivated, has a realistic attitude as to the cause of the communicative problem, is flexible and adaptable, has a measurable hearing loss of 25 db HTL or more, has adequate vision and finger-hand-arm dexterity, has few actual financial worries, and has a good friend or relative who can team-mate the entire process. Unfortunately, this ideal patient may not exist. A Feasibility Scale assists the audiologist in predicting success of hearing aid experience for a specific client. Four classifications for prognosis are located at the bottom of the Scale, and based on the arithmetic total, will suggest the "success" prediction for the subject.

The scoring of the Scale is accomplished by the use of a single page recording form. Not all of the eleven factors receive equal emphasis on the Scale. Factors of motivation, self assessment, and magnitude and shift in the hearing levels are weighted more heavily because of their importance to the older person.

The decision-making process on the part of the audiologist

as to which numerical value to attach before weighting calculations are added to assist the clinician in reaching an objective score.

Four prognostic predictions are possible from the employment of the FSPHAU. They include the following:

Positive — with scores of 76 — 100%

Equivocal — with scores of 61 — 75%

Limited — with scores of 41 — 60%

and **Very Limited** — with scores below 41%.

The clinical employment of the Feasibility Scale for Predicting Hearing Aid Use (FSPHAU) provides us with analytical support for decision making regarding the usefulness of recommended amplification for our older patients. It identifies the client who will need additional study, orientation and counseling regarding the benefits and limitations of amplification. For a limited number of clients, the Scale points out a population which may need alternative programs to help them improve their receptive language base. The Scale is an effective instrument in that it assists the audiologist in studying key and critical areas related to the client and his probable success in making the adjustment to a hearing aid. It gives analytical structure to the clinical observations made by the audiologist on behalf of the client. The Scale is an effective tool.

The Negative On/Off Effect In Cochlear and Early Stapedial Otosclerosis

Brian D. Forquer, M.S.
James L. Sheehy, M.D.
Otolitic Medical Group
Los Angeles, California

ABSTRACT

Acoustic reflex patterns were reviewed for one hundred patients suspected of having cochlear otosclerosis and 73 patients with confirmed stapedial otosclerosis and mild con-

(Continued on p. 5)

Abstracts

(Continued from p. 4)

ductive hearing losses of less than five years duration. Three abnormal reflex patterns were exhibited by these patients — negative on/off, efferent, and no response. The negative on/off pattern was found to be equally as common for each of the subject groups. The efferent pattern was much more frequent in the early stapedial otosclerosis group. In cases where the patient has a mild sensorineural hearing loss, excellent speech discrimination, and family history of hearing loss, the presence of the negative on/off is now considered indicative of cochlear otosclerosis.

Speech-Band Audiometry

Barbara Franklin, Ph.D.
San Francisco State University

Although there is agreement that speech is the most effective elicitor of response for certain populations, it has not been used because of the inability to obtain quantitative information corresponding to an audiogram. This investigator has developed a new audiometric testing procedure using filtered speech bands which can be used as an alternative or supplement to pure-tone audiometry (United States Patent #4,139,730, **Method of Testing Human Auditory Response**, Feb. 13, 1979, Inventor: Barbara Franklin). The phrase "ah clap clap" has been sent through a filter with various high-and-low-frequency cut-off points. The frequency range of the bands was varied in order to maintain equal energy levels in each of the five speech bands. Each speech band is centered at one of the test frequencies on an audiometer, from 250 to 4000 Hz.

Presentation of Speech Bands

The speech band cassettes are played through the tape circuit of the audiometer. Because of the nature of the populations typically tested with speech bands, an ascending procedure is recommended. For newborns, infants, young children, low-functioning and hard-to-test individuals of all ages, the novelty of the stimulus is crucial to the response.

Results and Discussion

In order to establish the validity of these narrow speech bands, audiograms were obtained by this investigator on easy-to-test hearing-impaired subjects, and a comparison was made of their pure-tone and speech-band audiograms. It was found that their pure-tone and speech-band audiograms were remarkably similar at each test frequency.

Large-scale field testing of speech-band audiometry has been completed at selected sites throughout the country. The speech bands were found to be effective with a wide range of populations, including: newborns, children, retarded and deaf-blind children and adults, and hard-to-test individuals. The speech bands were presented using a wide variety of test procedures including:

1. Observing of behavioral changes
2. Orienting
3. Conditioning to visual reinforcement
4. COR audiometry
5. Localization
6. Hand raising
7. Play audiometry

There was a close correspondence between the speech-band and pure-tone audiograms for easy-to-test subjects. Thresholds for a number of subjects were substantially lower for the speech bands than when standard audiometric procedures were employed, and speech-band audiograms were obtained for many subjects who previously were untestable. The speech bands were successfully used to obtain air conduction (free field and under earphones), bone conduction, and aided thresholds.

It seems to this investigator that the use of narrow speech bands to test hearing is a logical and natural clinical application of the neurophysiologic data available on the development of auditory behavior.

Adult-Onset Hearing Impairment Rehabilitative Directions

B. Gail Frankel, M.A.
Health Care Research Unit
The University of Western Ontario
London, Ontario, Canada
and
Susan H. Brainerd, Ph.D.
Department of Communicative Disorders
The University of Western Ontario
London, Ontario, Canada

Little investigation has been done in the area of handicap experienced by adults with acquired hearing impairment. In our view, the circumstances — economic, social and psychological — that confront such individuals are likely to be significant and are deserving of more study. This study was conducted to assess adaptation to adult-onset hearing impairment. Adaptation is seen as multi-dimensional construct assessed in terms of: 1) variations in experienced handicap within specific categories of hearing loss; 2) psychological well-being; 3) interpersonal relationships and social interaction; and 4) educational and occupational achievement. One of the specific objectives involved the compilation of the results of the study into a meaningful guide for those engaged in aural rehabilitation.

Our sample was comprised of individuals between the ages

of 18 and 50, who had received an audiological evaluation in the past 18 months, whose Pure Tone Average at 500, 1000 and 2000 Hz, was worse than 20 dB (ANSI, 1969) in at least one ear, and whose onset of hearing impairment was after the age of 16 years.

A questionnaire was designed to collect data from the sample of hearing-impaired adults. The self-administered questionnaire was divided into six major sections. These sections solicited information on general health, psychological well-being, social interaction, use of leisure time, social support and demographic information. In addition, we used two sets of items from the U. S. National Health Survey on hearing ability, the Ewertson and Birk-Nielsen Social Handicap Index, the Alperin Scale of Communication Function, and a set of items designed to elicit the respondents' feelings about how hearing impairment affects work role performance.

Our second source of data for the study was the individual's audiology clinic file. Data taken from the files included pure tone results for air and bone conduction, speech reception thresholds, word discrimination scores and site-of-lesion test results. The final sample excluded persons whose onset of impairment was before the age of 16 who could not be screened at the initial selection, resulting in a total of 478 individuals who met all the criteria for inclusion.

This paper focuses on the results of the study that have particular relevance for those involved in aural rehabilitation. Specifically, we will examine the relationship between actual hearing impairment, perceived handicap, and a number of psychological variables. The better ear pure-tone average serves as our measure of hearing impairment. In our sample, the better ear PTA ranges from 0 to 87 dB with a mean of 17.8.

Each of the study participants completed the Social Handicap Index, developed by Ewertson and Birk-Nielsen (1973). The Social Handicap Index contains 21 items, 10 phrased positively and 11 negatively. Scores on this scale were converted to percentages, yielding a range of 0, "no perceived handicap", to 100, "severe perceived handicap". Our sample had SHI scores ranging from 2 to 100 with a mean of 41.4.

We felt that the individual's attitudes to various communication situations were of considerable importance in rehabilitation. Accordingly, participants were asked to complete the Alperin Scale of Communication Function. Scores were calculated on the four sub-scales of the Alperin: family, self, social-vocational and general communication. These scores have a potential range of one to seven, with higher scores indicating more positive or more healthy attitudes.

In our view, the goal of all rehabilitation is personal well-being. Thus, we felt it was important to examine this dimension on our sample in order to determine the correlates of well-being. Various aspects of psychological well-being, including anxiety, depression, anger, paranoia and self-

esteem were assessed. Scores on each of the five scales ranged from one to five, with high scores indicating a greater tendency toward the particular characteristic being measured.

Recent literature has shown that an individual's perception that he is loved, esteemed and part of a network of mutual obligations can act as a mediator in illness outcome. It was our belief that this factor — called "perceived social support" — might play an important role in adaptation to hearing loss, and therefore might be of relevance to aural rehabilitation. Social support was measured through the use of a story identification technique. Potential scores ranged from one to five with high scores indicating higher levels of perceived support.

The final measure is one developed especially for this study. Its primary purpose was to assess how much an individual feels that his work role performance is influenced by his hearing loss. It may well contain other elements, and since our examination of its validity has only begun, we can not make any further statements about its meaning at this time. Scores on this scale range from one to five, with higher scores associated with the feeling that hearing loss does not affect work role performance.

Our strategy for analysis in this paper was to examine correlations among these variables. A preliminary step when one uses multi-item indices involves the assessment of the internal consistency or reliability of the scales developed. Chronbach's coefficient alpha was calculated for each scale. All the coefficients were well within acceptable limits.

According to Ewertson and Birk-Nielsen, individuals with greater hearing loss are likely to experience significant perceived handicap, while persons with minor hearing loss rarely experience significant social handicap. They report that actual impairment and perceived handicap are highly correlated. Our data tend not to support their findings. In our sample, the average better ear hearing loss is 17.8 dB; yet the average score for this sample on the Social Handicap Index is 41.4, and the correlation between the two measures is a modest .38. Studying an audiogram, therefore, may not provide a totally accurate picture of the difficulties an individual could be experiencing in everyday life.

The Alperin Scale provides clinicians with information on specific problem areas for individuals with hearing loss. Each of the four Alperin sub-scales was considerably more strongly correlated with perceived handicap than with actual impairment. Once again, how an individual experiences his hearing loss seems to be more clinically significant than his actual impairment.

The dimensions of emotional well-being measured in our study are essentially unrelated to Better-ear Pure Tone Average. It was evident that individuals who perceive themselves to be handicapped, regardless of their actual impairment, are more likely to be experiencing emotional difficulties.

THE VICON METRAPHONIC

No one wants to experience a hearing loss. We at Vicon understand this feeling, and make your patient's hearing needs our tantamount obligation. Call Toll Free: 1-800-525-9626 for information on our stock line of metraphonic instruments, models OE 123 and OE 124. Also available are a complete variety of hearing instruments and Tinnitus maskers, including such favorites as models OE 562, OE 130, OE 140, and our ever popular temple aid, model T-82, the prescriptive instrument with a choice of seven different responses. Our Tinnitus masker line

includes models S-344, S-564, S-564 HF, and the versatile S-274 Combination hearing aid/Tinnitus masker. Improved Apritons and newly modified Tinnitus Comparators will gladly be made to order. Watch for the new Apriton III coming soon, with newly modified battery requirements. Reasonably priced even for Vicon.

VICON
WITH ITS SIGHTS AND SOUNDS
ON THE FUTURE

FOR THE FIRST TIME IMPEDANCE AND PURE TONE SCREENING MADE EASY!

The MD-1 MICROPROCESSOR has been designed with prime considerations of accuracy and ease of use. The MD-1 MICROPROCESSOR is simple to operate, automatic, accurate, and reliable. The probe mechanism contains many unique features, and because it employs an external seal and an automatic pump, testing is quick and easy. For the first time professionals can confidently use volunteer help.

The MD-1 is the only solid state microprocessor unit, with all designated features, in the field today. Repairs are minimized by solid state construction. The MD-1 MICROPROCESSOR meets or exceeds all ANSI standards and is fully guaranteed for one year from the date of receipt against any defect in workmanship.

There is nothing like it on the market today.

(Continued from page 5)

One would expect that individuals with more serious hearing loss would be experiencing more difficulties in work role performance. This is borne out by our data, both in the Alpinar Social-Vocational sub-scale and in the "work performance" scale developed for this study. Both scales have somewhat modest correlations with Better Ear Pure Tone average; in fact, they represent the largest correlations with the actual impairment measures. However, once again the correlations with perceived handicap are considerably higher and are in the range where their significance for aural rehabilitation cannot be underestimated.

Social support does not appear to have strong relationships with either perceived handicap or actual impairment. This is not an unexpected finding, since we see this variable playing an important role as a mediator or facilitator in adaptation. That role will be examined in future reports on this study.

In summary, what we have found in this fairly straightforward preliminary analysis is that standard diagnostic tests do not provide a complete picture of how hearing loss affects individuals in everyday life. Persons with clinically minor hearing impairment appear to be experiencing some difficulties in adjustment — emotionally, occupationally and socially.

What does this mean for those interested in aural rehabilitation? Simply stated, we feel that it may be necessary to extend the assessment procedure beyond the routine diagnostic test battery to include some other aspects of functioning. Audiologists make judgments about the needs for auditory and visual rehabilitation from their inspections of test results and case histories. Our results indicate that a "normal" pure tone average can be associated with a greater than expected perceived handicap, and a variety of emotional problems. Aural rehabilitation may need to consider the importance of individual perceptions and of other psychological and social factors in order to provide more complete service to the hearing impaired.

Basic Guidance For Prosthesis Utilization

Norma Bain Norton, M.A.

Fitting a well selected prosthesis and offering an hour or two of counseling is insufficient rehabilitation for the adult suffering from a severe to profound hearing impairment. Nor does it necessarily meet the needs of the moderately hearing impaired adult who exhibits very poor speech discrimination. The critical issues in promoting prosthesis use for any level

of hearing loss appear to be 1) the choice of an appropriate device, 2) a scientifically based prosthesis selection process, 3) the client's and associates' motivation, and 4) the clients' understanding of the ramifications of prosthesis use. A basic guidance program has been designed and put into practice which stimulates early prosthesis use. It provides orientation and support through counseling, sequential auditory cue training, directed and non-directed behavior modification techniques for communication skill improvement, and leads into a home study program. Home study is considered essential in supporting self-helping, self-directing behavior on the part of the adult client.

These programs and materials were initially developed for deafened adults in an experimental single electrode cochlear implant program at the Ear Research Institute. The program evolved from work with 18 hearing impaired adults with bilateral warble tone averages poorer than 95 dB HL, ANSI. A subject group of 24 adults with the same or worse hearing levels were trained with various revisions of the procedures and materials. Additional subjects with hearing aids and vibrotactile devices have used the materials which are now being modified for those adults experiencing moderate to severe loss.

The basic guidance for prosthesis revolves around a nucleus program of 26 hours. The recommendation is for 10 direct contact sessions over no less than 2 weeks. These direct contacts may vary from a total of 10 to 30 or more hours depending on the communication needs and skills of the client. A major portion of the program can and should be conducted in groups. The home study program can be completed at the client's own pace in 6 months or less. Additional therapy may be suitable for those adults who request it or who have very poor communication skills. Initially, basic guidance sessions focus on refinement or redevelopment of critical listening ability. Minimal cue training of approximately 6 to 8 hours graphically reinforces for the client the multiple uses of even partial or distorted speech and environmental and speech sounds.

The beginning speech training materials can be differentiated or identified solely by temporal or by a combination of temporal and intensity parameters. The client relies on prosody, intonational and/or suprasegmental features for contrast and emphasis cues. There is, as yet, no standard terminology which describes these interchanging perceptual concepts, and no appropriate methodology exists for analyzing them.

The importance of differentiating these cues for profoundly deafened adults became evident in therapy and when results were reviewed from the Norton Rhyme Test, which was developed to examine error patterns between primary phrases (Norton, 1979; Eisenberg and Norton, 1978). Final plosives in the closed sets of 4 consonant-nucleus-consonant words were more distinguishable (90% correct) than any other features.

What could be called cuing on the absence of sound was, in reality, cuing on the modification of the vowel. From tests and therapy sessions with over 60 adults even remnants of the sophisticated and recognizable temporal processing seem to provide dependable cues for the deafened adult who has experienced the normal process.

The materials developed for training critical listening ability follow a hierarchy of sequentially graded perceptual tasks from duration cues only, to duration and intensity cues, on to limited phonemic place of production comparisons. The differentiations begin with single words, same/not same, and lead to detection of practiced and not practiced words or sentences from among intracategorical events. The most difficult task is recognition of phonemes or words embedded in sentences. The tasks are practiced first audio-visually and then in the auditory alone condition. They are made more complicated by 1) enlarging the closed sets, 2) using more complex or longer contrasts, words or sentences, 3) using noise interference, and 4) using recorded vs. live presentation, with or without noise interference.

An arbitrary decision was made to specify a task by task minimal cue performance level of 75%. That is, a "cannot fail" task was considered essential for people who must deal with perceptual failures daily. Thus, the client has immediate success because of the choice of materials, and is taught exactly what he/she is to use for the cue in each task.

Besides the minimal cue training, the basic guidance program also addresses preliminary speechreading training and voice level monitoring, all of which are continued with the home workbook and audio cassettes. Three speechreading activities are stressed 1) review of the visual characteristics of speech sounds for those who need it, 2) teaching the client and relative of friend the DeFilippo and Scott tracking method (1978) with specified strategies for home practice, and 3) group therapy examining speechreading techniques. The latter is a 10 step non-directive process aimed at helping the clients develop practical speechreading strategies no matter what their over-all skill. Group counseling sessions during basic guidance as well as assignments during the home study period concentrate on those externally and internally controllable activities or mind sets which reduce barriers to communication.

A preliminary polling of the initial group of profoundly deafened clients in the implant program revealed their worry and concern over inability to control their voices. Voice level, vocal quality, and prosody and intonation appear to be the most prevalent speech/voice areas effected by hearing loss in adults, to which the least amount of study and research design attention has been devoted (Reed, 1980). Markedly effected are word per minute rates, amount and rate of pauses, pitch and loudness stress, and pitch contours. Deafened adults are not aware of the technical ramifications of intonation and voice level interferences resulting from hearing loss, but they are acutely aware of a reduction in communication effectiveness. The fine nuances of intonation and prosody are lost influencing the reactions of others to the hearing impaired person.

The range of acceptable articulation seems to be wider within the normal hearing and hearing impaired populations compared to that of prosody and intonation interferences. During basic guidance and home study the client learns to graph room and situation acoustics to better judge the voice levels needed and then receives therapy by an experienced speech pathologist.

The attempt to relate therapy task results, effects of use over time of a prosthesis, and pre/post test scores can lead to interesting conclusions. But the careful graphing of goals throughout the program reveals for both client and staff progress or lack of it, and the need for goal review or program redirection. Assignment reports and questionnaires re daily usage and quality of life changes provide follow-up during the home study period.

A carefully nurtured awareness of the availability and usefulness of partial auditory cues can help the adult become a critical listener with a prosthesis. Other program services support the client's moves toward competence in daily life. This is no small matter. One half of those fitted with hearing aids appear to need such guidance and support.

Adult Auditory-Visual Training

Dean C. Garstecki, Ph.D.
Northwestern University

This paper describes an experimental approach toward the evaluation and treatment of auditory-visual communication problems in adults with acquired hearing impairment. In the program, both self-report and bisensory evaluation procedures are used along with other measures in determining the need for auditory-visual communication training and for designing a client-centered remediation program.

Subject measures include use of referral source information, case history and interview data and client self-report of hearing handicap. The revised Hearing Performance Inventory (Lamb, et al, 1979) is used for determining overall communication skill as well as differences in auditory and auditory-visual communication. It is used to determine the client's ability to self-manage communication problems.

Objective measures include an assessment of hearing acuity, screening of visual acuity and evaluation of sentence perception ability. Standard audiometric test procedures are used to assess hearing acuity. A Snellen chart is used to obtain an estimate of binocular visual acuity at the usual screening distance of 20 feet and also at a 1 meter

conversational speech distance. Finally, a videotape recording of one list of the Utley Lipreading Test sentences is presented.

The videotape is presented to each client within a nine foot viewing distance. Primary and competing audio signals are mixed at a 0 dB PM/CM ratio and presented at 60 dB SPL. This is done to obtain a controlled measure of auditory-visual sentence perception under a commonly encountered, moderately difficult, listening condition. Clients view each sentence one time only. Their written responses are scored according to a numeric weighting system devised by Miner (1969).

Remediation Procedure

Evaluation results provide baseline data for the development of an auditory-visual communication training program. The program emphasizes training through systematic manipulation of four message parameters: message type, competing noise type, primary message-competing noise level, and the use of situational cues. Audible presentation of Utley sentences in noise without cues constitutes the baseline condition.

Training begins where the client is able to achieve a pre-determined performance criterion level. To determine the starting point, the four message parameters are systematically varied to increase message redundancy by increasing message content, changing competing signal type and decreasing level of presentation, and by adding relevant situational cues. The procedure is to obtain a measure of baseline performance, then probe performance at higher numbered levels where message redundancy is increased. The point at which the pre-determined performance criterion is met is termed the ceiling level. If a pre-determined criterion level cannot be achieved within this scheme, the process is continued at an increased primary to competing message ratio.

Furthering the process, the noise type is changed at the increased primary to competing message ratio. Finally, the primary message may be presented without a competing message.

Baseline and ceiling performance levels circumscribe the short-term remediation goals. The short-term goals are to develop improved communication skills at each successful level of decreasing redundancy from ceiling to baseline levels, until either no additional progress is attained or until satisfactory baseline level performance is achieved.

In summary, complementary use of self-report and auditory-visual speech perception procedures has resulted in a comprehensive, logically progressing program of improvement of overall communication ability for some hearing-impaired adults. These preliminary findings suggest that

there may be some benefit in applying this approach in designing rehabilitative programs for other communicatively handicapped people. Further investigation of the use of this organizational approach, of the relative importance of various message parameters inherent in everyday communication, and the control of these parameters in the design of communication-remediation programs, is currently underway.

Computer Based Analysis of Language For Evaluation And Treatment of Deaf Children

Marian MacEachron
and
Barbara Parkhurst
Graduate School and University Center,
City University of New York

The linguistic output of the hearing impaired is often seriously deficient. Language development is certainly slower than normal and in some cases appears to follow patterns that differ from normal ones. There are also great individual differences in language development and usage among hearing impaired children. What appears to be needed is intense individualized remedial language training programs. Designing and executing such programs is a formidable time-consuming task because of:

- (1) The amount of data that must be collected and interpreted in longitudinal studies. These are necessary to increase our understanding of language development in the hearing impaired.
- (2) The detailed evaluation that must be performed for each child.
- (3) The amount of individualized training necessary.

We have been working with a computer program, originally developed by Newcomb (1963) at the Center for Communications Research, which we feel will be able to simplify some aspects of these tasks. The program does a very detailed syntactic analysis of written language along with error recognition and correction. It has some semantic capabilities but these are quite limited. It can reduce the burden placed on speech/language pathologists and teachers of the deaf by rather quickly analyzing the syntactic and lexical aspects of written language for data collection and individual evaluation purposes. It can also be used as a tutorial device.

The program is called PERC (Parsing with Error Recognition and Correction). PERC is written in FORTRAN and parses a sentence by testing the input string of word classes against programmed graph structures that describe grammatical sentences. The word class string is generated by a

Wullstein Awarded International Prize

The 1980 edition of the Amplifon Research and Studies Centre International Prize — one of the most important recognitions for studies or activities connected with the fight against deafness — has been awarded to a West German Doctor, Prof. Horst Ludwig Wullstein of Wurzburg, for the brilliant results he obtained in the middle ear surgery.

Prof. Wullstein's research and work are universally known by scientists. In particular, he has introduced in the treatment of chronic otitis media the basic principles of the middle ear physiology, developing, with tympanoplasty, original surgical techniques aiming at restoring and preserving the hearing function.

The CRS International Prize was created ten years ago to honor scientists who distinguished themselves, anywhere in the world, in the fight against deafness. The Prize Awarding Committee decreed this year to bring to the public opinion's attention the achievements of an ear surgeon, whose imposing amount of both theoretical studies and practical work has positively enhanced the science of Audiology.

For him and others, a three year warranty on Audiotone's modular in-the-ear hearing aid.

Your next Audiotone client . . . there'll be a lot more coming like him.

He's one of the 'Baby Boom' generation . . .

Which represents 30% of our current population. These forty-plus adults are moving into the hearing aid prospect category. It's a large group, over and above your existing market.

And these people really enjoy listening. Take our trucker friend. His \$94,000 tractor sports

chrome air horns, a color TV (over the double bed), and AM-FM stereo/tape deck with a power booster driving six 3-way speakers and 120 channel CB radio. He's a good example of how this group takes advantage of today's technological advances. In their homes . . . cars . . . trucks . . . and now in their ears.

We've packaged our most advanced technology into an easy-to-use in-the-ear (ITE) system.

Like building blocks, our soft tips or full shell molds simply snap on to our aid. This modularity allows you to immediately fit your customer with the aid he needs. Exactly when he wants it . . . now! Which saves you time. Time you could use to help another customer. Custom molds can also be used. That modularity also means, should the aid need servicing, you can simply snap in another unit and send your customer happily truckin' on.

Small in size, but big in features.

Stock molds are vented and adjustable. Soft material shapes easily for a snug, comfortable fit to please the hardest-ridin' driver. Response trimmer to adjust for high or low response. Raised and ribbed volume control designed for easy customer use.

New modular E-3 features a 3 year warranty. Shown with optional ear molds.

Get in on the ITE modular sales boom NOW!

Last year more than one in three customers asked for an ITE. That's phenomenal growth in only a few years. Plus, with the Audiotone Modular ITE concept, the future promises to be even brighter.

"Breaker-breaker 1-9 for more information"

There's lots more to tell you, like our **three year warranty**, and optional three year loss or damage coverage. Give us a call . . . 10-4.

Join Up - Special Membership Offer

The American Audiology Society was formed in October, 1974. In June, 1978, after a vote by the members of the Society, the name was changed to the American Auditory Society. The following provides basic information regarding the Society.

What is the Purpose Of The Society?

The primary aims of the Society are to increase knowledge of human hearing, promote conservation of hearing, and foster habilitation and rehabilitation of aurally impaired individuals. To attain these goals, the Society will coordinate and disseminate information, particularly through the holding of regular meetings, and the publishing of reports. Because of the multiple disciplinary nature of the Society's membership (audiology, otolaryngology, deaf education, hearing aid engineering, psychoacoustics, etc.), the Society will provide a formal platform for the interchange of information from allied professional fields.

Who Can Be A Member?

There are two categories of members: Active and Associate.

Active membership is open to individuals holding at least a baccalaureate degree from a certified college or university. To become an Associate of the Society, an applicant need only to support the aims of the Society. Associates do not have voting privileges, but do receive all publications and have all other rights and privileges. The Society is based primarily within the United States, but there is no geographic limitation on membership.

When And Where Will Meetings Take Place?

An annual meeting will be scheduled to take place either day before or after annual meetings of The American Academy of Otolaryngology (AAO) or The American Speech and Hearing Association (ASHA).

Will There Be A Journal?

The Society publishes *Ear and Hearing* and *Corti's Organ*. *Ear and Hearing* has a scientific format and is

issued bimonthly (6 issues per year). *Corti's Organ* is published on a triannual basis. The format of *Corti's Organ* is informal and the purpose of the publication is to keep members aware of the Society's activities and other notable events.

How Much Are Dues?

Annual dues for 1981 are \$29.00. Because the Society will not concern itself with political issues, such as licensure, certification, etc., dues will remain reasonable. All members receive both of the publications as part of their dues.

How Does One Join The Society?

To become a member submit an application with an endorsement from two active members to the Secretary/Treasurer. For more information write: Ross J. Roeser, Ph.D., Secretary/Treasurer, American Auditory Society, 1966 Inwood Road, Dallas, Texas 75235.

Special Membership Offer

The requirements for Active Membership in AAS include the minimum of a bachelor's degree or the equivalent in experience and signatures of two active members (see above). Until August 1, 1981, applications will be accepted without the accompanying signatures for applicants who do not know two members. The Secretary/Treasurer's office will obtain the necessary signatures from two active members.

THIEME-STRATTON!

Roeser & Downs AUDITORY DISORDERS IN SCHOOL CHILDREN

Introducing the most current and innovative information on the identification and remediation of hearing loss in school aged children... Under the auspices of Ross J. Roeser, Ph.D. and Marion P. Downs, M.A., D.H.S., 20 seasoned experts offer practical advice in all pertinent areas including:

- Relevant State and Federal Laws
- Identification of Hearing Loss and Auditory Problems
- Remediation of Auditory Disorders

Clinicians, teachers and students alike will benefit from this collection of state-of-the-art knowledge in an area never before covered so comprehensively.
