The President's Message

(Continued from p. 1)

each of these instances I have been lucky enough to work alongside clinical and basic scientists from professional areas other than but adjacent to my own, always with a minimum of protocol but a maximum of sharing of professional interests and expertise.

I make no apologies for this dig into personal history, although I abhor the practice (which is tantamount to telling your friends about your experiences during the war). The reason I burden you with the details is that on that day many years ago, when I was asked to start the Deafness or Hearing Clinic I sowed the seeds of a lifetime philosophy which has stayed with me; it has been reinforced by other experiences and is as timely today as it was then; it is of fundamental importance to the practice of scientifically-based medicine, to clinically-directed research in medicine and to our area of professional interest in particular — the understanding of human hearing, the conservation of hearing and the habilitation and rehabilitation of the hearing impaired.

I recognized in those early days in London that the most effective way or the only way in which I could contribute to the area of clinical medical science that I was entering had to be in close collaboration with scientists in adjacent disciplines.

Today, the ideas and principles I formulated as a fledgling otolaryngology resident and investigator are no less pertinent; in fact they have grown in importance to the point where I believe the health of our shared interest in the hearing impaired is threatened unless we restate and revitalize some basic tenets. Every physician has a responsibility to his profession and his patients to provide competent medical care based on sound scientific principles; so each physician must, among so many other things these days, be trained as a scientist and maintain contact with the scientific aspects of his profession throughout his professional life. More to the point, those of us who feel the urge to be involved in clinical research must recognize that it is difficult now to "go it alone," unless we have most unusual training and expertise in research methods. Clinical research has become more of a joint venture than it ever was before and major advances in the health sciences are most commonly made now by teams of investigators rather than by the solitary investigator working in isolation. But the physician has always had and continues to have a role of great importance to play, just as is true of the other partners, in this research consortium.

Now I have come full circle. The number of physicians involved in research is declining, for many complex reasons. But one of those reasons may be that we have, to some extent, lost sight of the ideas I thought erroneously that I was perceiving for the first time the day I walked into a residency program. Health care has become a complex industry and clinical research into health science, although no more or less difficult, has become and continues to grow more complex. We each have a role to play, but only if there is interdisciplinary collaboration can research be most cost-effective and lead to significant improvement in patient care.

It is particularly appropriate that I share these personal thoughts and experiences with you in *Corti's Organ*, the house journal of the American Auditory Society; here we have a new society pledged to the support of not merely one or two of the many professional areas involved in hearing and hearing impairment, but all of them — audiology, education, habilitation, medical or surgical treatment and rehabilitation. I congratulate those readers who are members of this Society and who by joining it, have cast their vote for collaboration in clinical research and the care of the hearing impaired and deaf. Those readers who are not yet members, particularly physicians, I urge to consider joining to lend support to the concept of interdisciplinary collaboration in our common field of interest.

More Abstracts

(Continued from p. 8)

lexical component which contains a dictionary search, morphological processor and a permuter for words having more than one possible word class. The dictionary contains the English words and a set of codes describing their word classes and special functions such as verb type, adverb position and determiner order. An error is recognized when the input string fails to match any programmed structure; the error is identified by the point of failure. When the program operates in what we call the internal correction mode, the word class string is modified to correct the error and processing continues. It is important to note that this modification does not alter the input sentence; the final printout contains and identifies the error.

When used as described above, PERC can supply us with the following information about input sentences:

- (1) phrase structure analysis
- (2) part of speech analysis
- (3) error analysis
- (4) gross lexical counts such as word counts, sentence counts, words per sentence
- (5) complexity measures such as type/token ratio and subordination ratio
- (6) a single index of error severity

Thus, using this mode, a great deal of longitudinal data

Don W. Worthington Ph.D. (1969 Northwestern University), Director of Audiology and Vestibular Services, Boys Town Institute for Communication Disorders in Children, 555 North 30th Street, Omaha, Nebraska 68131.

I have never been known as one who rushes out and joins each new organization that is formed. If an organization has nothing to offer its members, either personally or professionally, then I have no time for that involvement. With this philosophy, I studied the aims, objectives and progress of the American Auditory Society for several years before applying for membership. I am convinced that this organization is unique in providing membership opportunities to a diverse multi-disciplinary group of professionals dedicated to all aspects of human hearing. The publications and annual meetings of the Society offer the best possible avenue for cross discipline education and involvement. It allows each member of the Society an opportunity to assume equal responsibility and input while minimizing "territorial rights". One can correctly say, the Society facilitates cross professional communication. These efforts must be sustained in the future.

More Abstracts (Continued from p. 19)

can be analyzed in a short period of time. Or, a large number of children can be evaluated for purposes of record keeping and designing individualized treatment programs.

The internal error correction feature of PERC can be bypassed, so that the program can operate in an interactive mode, where it recognizes errors but requires the user to correct them. It is hoped that in this form it will serve as a tutorial device, allowing the older child an opportunity for

individualized practice with immediate feedback.

When this interactive mode is used, after the student makes the required error correction, the final printout contains the corrected form of the sentence. However, a listing of errors made before correction appears along with the detailed structural analysis. Thus the interactive mode can also give a record of progress.

Conclusion

Our experiences with PERC have demonstrated its potential for language analysis and teaching. Pilot research (Parkhurst and MacEachron, 1979, 1980) has demonstrated its ability to parse sentences produced by children with severe hearing impairments. Longitudinal studies of the language of hearing impaired children are being initiated at this time. Further developments in the program for evaluation and teaching purposes are planned.

Test-Retest Reliability Of A Distinctive Feature Different Test For Hearing Aid Evaluation

Pat Feeney
Iowa Head and Neck Associates
and
J. Richard Franks
Washington State University

This study was undertaken to develop and examine the reliability of new test material and procedures which might meet the requirements of sensitivity, reliability, and brevity desired in comparative hearing aid evaluations.

Three steps were taken to increase sensitivity. First, distinctive features were used so that a relatively large number of speech characteristics could be evaluated using a small number of stimuli.

Second, to further increase sensitivity, 13 consonants found to be frequently confused by hearing impaired listeners were selected. The thirteen consonants chosen were: /b, t, d, f, k, p, s, g, t, ch, th, th, v/.

Third, signal-to-noise ratios were adjusted to place the scores on the steepest portion of the articulation curve.

The Distinctive Feature Difference Test was prepared using the following procedures. Each of the previously indicated phonemes was recorded in the phrase /A C I I/ by a speaker of general American English. Ten scramblings of the stimulus phrases were recorded with the carrier phrase "you will mark" preceding each item.

A second tape was made from the original and passed through a B & K spectrum shaper for low-pass filtering of 12 dB per octave at 800 Hz. CID W-22 Lists were also recorded through the filter.

A closed response set was chosen for the test. Thirteen consonants as multiple choice alternatives for the consonants were provided for each response. The subjects were simply asked to select and circle the consonant heard in the stimulus phrase. The consonants presented in the test by the symbols: P, G (George), K, B, F, T, D, Th (voiced), Th (unvoiced), and Sh.

The test was administered to twenty-one normal and twenty hearing impaired subjects.

Test Administration

The filtered DFD Test recording was presented to normal subjects to simulate a high frequency hearing impairment. A signal-to-noise ratio of +20 was used, with at 70 dBA and a speech-band competing noise.

For the normal group, the test materials were prepared means of a group audiometer with matched TD phones. The normal subjects first received four practice trials with the DFD Test in quiet and in noise followed by lists which constituted the test and retest trials. The subjects were also given four practice trials with the W-22 words. Then full lists consisting of Lists III-A were presented. These lists constituted the retest for the W-22 words.

For the hearing impaired group, each subject was given the test answer form after which six to ten words were used for the subjects to learn the test procedure. A signal-to-noise ratio, using pink or speech noise, yielding 75 percent of the DFD maximum score after the first four trials. The 75 percent level was placed performance on the upper linear portion of the articulation curve. Finally, a test list was presented at the signal-to-noise ratio followed by a one-minute break and a retest. The stimuli were presented at a comfortable level through headphones.

Results

For comparison, the Distinctive Feature Difference Test was scored both on the basis of distinctive feature differences and on the basis of the identification of the correct word. The smallest mean test-retest difference and standard deviation were obtained with the DFD Test scored by distinctive feature differences. This was true for both the hearing loss subjects and the simulated loss group. Scores, representing only the simulated loss group, the largest mean test-retest difference and a larger deviation than the DFD scores.

T-tests for related means were applied to the data of the simulated hearing loss group and the hearing group. The mean test-retest differences for the DFD Test the phonemic scores were not statistically significant; however, the test-retest mean differences for the W-22 Lists were statistically significant at the .01 level.

Intra-subject consistency is vital when considering

(Continued on p. 21)

The smoothest sound in hearing aids ever

The  E17VF, E17CF, E17HC and E19VF earettes

Hearing aids from OTICON CORPORATION with the patented "Acoustic Valve" technology have gained world wide acceptance because of exceptional sound quality.

Nature has provided us with an amplifier—the external ear. The sound pressure at the ear drum of an open ear increases up to 18 dB at the higher frequencies (the ear's free field gain). The hearing aid, when fitted with an occluded or vented mold destroys this natural gain (insertion loss). Then it becomes the duty of the hearing aid to first recover the ear's free field gain before dealing with the actual hearing loss. Those functions can be accomplished by means of a smooth and steadily rising frequency response; A response from which the primary resonance peak (around 1 KHz) has been effectively removed. Oticon's patented ACOUSTIC VALVE does just that, and without side effects.

- Optimal speech intelligibility.
- Directional microphone to minimize background noises.
- Small, cosmetically appealing.
- Wind noise protected microphone.
- Sophisticated, yet highly dependable.

A unique new generation of hearing aids developed and engineered at the psycho-acoustic research center of the world's largest manufacturer of hearing aids.

Jackson Hole Rendezvous

A workshop designed specifically for clinical audiologists, hearing aid specialists, and otolaryngologists will be held in Jackson Hole, Wyoming, September 1-5 1981, at the Ramada Snow King Inn. Jackson Hole Rendezvous, a Conference for Hearing Health Professionals, will provide fifteen credits toward continuing education units required by various organizations and licensing boards. Accreditation by the American Medical Association and NIHIS of the National Hearing Aid Society is pending.

Members of the faculty are eminently qualified hearing health professionals, who will share innovative educational information with the attendees. Along with the outstanding lectures, the registration fee includes such activities as a float trip on the Snake River at the Base of the Grand Tetons, followed by a steak fry at the Triangle X Ranch, a guided bus tour of the Grand Teton National Park, and a boat ride on Jackson Lake with a lunch on Elk Island.

Members of the faculty include:
David P. Egolf, Ph.D., Assistant Professor, Electrical Engineering, University of Wyoming.

Geary A. McCandless, Ph.D., Professor, Speech Pathology/Audiology, Head of Audiology Department, University of Utah Medical Center.

Ralph A. Nelson, M.D., Otologist, House Otolologic Medical Group, Los Angeles, California.

Jerry L. Northern, Ph.D., Professor of Otolaryngology, Head of the Audiology Section University of Colorado Medical Center.

Martin S. Robinette, Ph.D., Professor of Audiology, University of Utah.

Darrell E. Rose, Ph.D., Director of Audiology, Mayo Clinic

Wayne J. Stabb, Ph.D., Vice President, Audiotone

Darrel L. Teter, Ph.D., Private Practice, Speech Pathology and Audiology, Denver, Colorado

David L. Wessell, Marketing Manager, Hearing and Test Instruments, Phonic Ear Inc.

Jack A. Willeford, Ph.D., Professor and Director, Divison of Audiology, Colorado State University.

Inquiries concerning the Jackson Hole Rendezvous should be made to the chairman of the committee, Michael W. Marion, Casper Clinic, 940 East 3rd Street, Casper, Wyoming 82601. Phone 307-265-3970.

Abstracts

(Continued from p. 20)

to evaluate and rank hearing aid performance. The DFD scores for both groups show strong test-retest consistency with scores differing by less than 7 percent. In contrast, only 52.5 percent of the simulated loss subjects exhibited test-retest differences less than 7 percent for the W-22 Lists.

In summary, the results of this investigation appear to support the reliability of the DFD Test and the noise competition procedure postulated

as meeting the requirements for an efficient and sensitive speech reception test for comparative hearing aid evaluation. However, it is recognized that the appropriateness of the DFD Test must be proven in actual clinical situations involving comparison of hearing aids with hearing impaired subjects. Nevertheless, the present study suggests that the test is worthy of further clinical and research examination.

our guarantee of excellence
in the field of hearing instrumentation

Siemens...
committed to better hearing

REXTON

Argosy alternatives for the hearing health care professional . . .

Fine, quality hearing instruments delivered to dispensers at very affordable prices under a liberal quantity discount schedule. At Argosy we sell Rexton precision instruments, featuring the latest in technology and styling. Our new, com-

plete earmold laboratory facilities. Acoustic Technologies, specializes in producing quality earmolds and acoustic couplers to meet the demands of the most discriminating professional and user.

Behind-The-Ear Instruments

Currently 18 models are available over all power classes. The line includes a tinnitus masker and several units with high frequency emphasis response. Most instruments feature compression. The versatility within the Rexton line is readily apparent, from the compact Mini Series to the popular 780. Rexton engineering assures you and the user of quality performance and durability.

The Mini 25 PP is pictured.

Body Instruments

The Power Master and Super Master are lightweight and cosmetically styled with a wide choice of receivers including bone-conduction and Y-cord fittings. Both are economical to operate on an AA penlite battery. A protective cap covers controls and microphone opening.

The Power Master 25 PP is pictured.

Eyeglass Instruments

A wide range of eyeglass units are available, including two bone conduction instruments. All air-conduction models are universal left and right and feature pre-cut, "snap-on" extensions for ease of fitting. Models are available for open coupler fittings, severe high frequency sloping losses, and push-pull circuitry for severe losses.

The Mini Compact is pictured.

The Mainstreamer

The individual wireless auditory training system is designed primarily for use by the mainstreamed student, yet it has application for many individuals outside the classroom. The use of transducer coils eliminates the need for any wires to the ear. Typical range of this system is in excess of 200 feet with good signal-to-noise ratio, even when worn under clothing.

Ear Replica

The Argosy Educational Series provides the dispenser with valuable educational tools for office, clinic, school and university use. The anatomical, 3-dimensional display accurately depicts the outer, middle, and inner ear in full color. The 8-inch high unit is molded of durable, color-fast plastic. A brochure, "REXTON INTRODUCES KEMAR", is also available through Argosy's educational program.

Exclusive U.S. distributor of
REXTON precision hearing
instruments.

TRACOUSTICS

PROGRAM III

THE PROGRAM III IS READY,
IN PRODUCTION, AND NOW IN
ROUTINE USE IN UNIVERSITIES,
SPEECH AND HEARING CENTERS,
HOSPITALS, ENT AND
AUDIOLOGY PRACTICES AND
SCHOOL SYSTEMS. AND THE
PROGRAM III HAS FEATURES
NEVER BEFORE FOUND IN A
CLINICAL AUDIOMETER.

ISN'T IT TIME YOU MOVED UP TO
THE AUDIOMETER OF THE '80s . . .

- TOUCH-BUTTON controls provide convenient, reliable selection of desired tests, input and output switching, frequency, hearing threshold level and taped speech.
- MICROPROCESSOR COMPUTER generates Continuous and Pulsed Tones, linearly swept Warble Tone, Narrow Band Noise and White, Pink and Speech Noise; instantaneously sets up the audiometer for all basic tests, and allows either automatic patient response testing or complete manual operation.
- DIGITALLY GENERATED NARROW BAND NOISE is the new ultimate masking signal.

- LIGHT EMITTING DIODE MATRICES display complete Air and Bone Thresholds for the left and right ears.
- CASSETTE PLAYBACK UNIT provides professional quality playback of standard audiometric tapes and introduces AUTO-PLAY for operator control of Speech Discrimination and Spondee word lists, with the repeatability of tape and the speed of live speech.
- COUNTER-TIMER-CLOCK includes convenient counter operation to score SRT's, a one second timer for Tone Decay and Time of Day.

Consider these features and the reliability of solid state switching, the convenience of completely flexible input and output switching, the availability of the new Narrow Band Noise signal without skirts, the opportunity to change the test programs by plugging in a new memory chip and you have the audiometer of the 1980s.

Fall/Winter 1981-82

Annual Meeting A Grand Success Over 135 Attend

A Long Day of Good Papers

Those who sat through the whole day of papers at the AAS Annual meeting Sept. 21 were rewarded with a variety of stimulating, provocative and informative talks by members and guests. A prize for the most presentations should go to Michael Seitz, who co-authored and presented three excellent papers. A prize should also be awarded to the most frequent questioner, Dave Lilly, whose well-considered questions kept things lively. Abstracts of the papers begin on page 5 of this issue.

The highlight of the meeting was the Carhart Memorial Lecture, given by Paul Ward. He described the results of a national committee's conclusions regarding the status of Research in Communication Disorders — a projection for the next decade.

Sailing Down The River With AAS, SENTAC & AAO

Over 120 people boarded the river boat Cotton Blossom for an evening's entertainment that combined groups from three organizations: AAS, SENTAC and the Academy. A relaxed two hours' cruise up the Mississippi on the paddle-wheeler featured cocktails and excellent hors d'oeuvres. The boat had been chartered by Charlie Anderson, as Tracoustics' contribution to the R & R of the societies.

Following the cruise the entire entourage walked through the streets of the French Quarter to Armands, a well-known restaurant where the banquet was held. The evening's entertainment was provided by a Cajun comedian who convulsed the group with his monologue and accent.

The entire evening was planned and executed by Mike Seidemann, who is the new president of SENTAC and was program chairman for the AAS meeting.

NAUNTON ON FOR 2ND TERM

Pres. Ralph Naunton

At the annual meeting of this Society Ralph Naunton graciously accepted a draft from the Executive Board to serve another term as President of AAS. He was urged to continue because of the feeling of the Board that a year has not been long enough to effect some of the ideas that he has had to expand the purview of the Society. It will also be expedient to have Ralph as president because the Board designated that next year's meeting be again held in conjunction with the Academy of Otolaryngology rather than with ASHA. The reason for this change of policy is that ASHA is meeting in Toronto next year, which would be difficult for members to attend and for a society to transport materials.

LaVonne Bergstrom was appointed program chairman for next year's meeting which will again be in New Orleans. Mike Seidemann was drafted to repeat his stellar performance as Local Arrangements Chairman for the meeting in New Orleans.

The minutes of the Executive Board meeting for September 20 are on page 3.

Highlights of 1981 Meeting

- Bergstrom named 1982 Program Chairman (Pg. 3)
- 1982 Meeting to be in New Orleans again (Pg. 3)
- Naunton appointed for unprecedented 2nd term (Pg. 1)
- Keith named 1983 Program Chairman - AAS to meet in Cincinnati (Pg. 4)
- New Executive Committee members announced (Pg. 3)

International Audiology Society Meets — Special Air Fare Available

For Registration

or

Submittal of Papers

For registration or submittal of papers write to:

XVI International Congress of Audiology
Secy.—Gen. Dr. Tapani Jauhiainen
Dept. Of Otolaryngology
Helsinki University Central Hospital
Haartmanin Katu 4 E
SF 00290 Helsinki 29, Finland

Sign Up For Finland

The numbers are growing of people planning to attend The International Auditory Congress in Helsinki, May 23-27, 1982. Spurred by the reasonable air fares that can be obtained — as low as \$611.00 round trip from New York, audiologists and otolaryngologists are hurriedly submitting papers that will put them on the program of the Congress.

[Ed. note: It has been our experience that any legitimate paper will be accepted for presentation by The International Auditory Society. Therefore you may be quite sure that you will be placed in the program if you submit.]

There will be a Pre-Congress meeting in Goteborg, Sweden for those who want to visit Sweden before going on to Finland. A package air-flight is being worked out at the most reasonable rates and information can be obtained from Marion Downs, Box B210, University of Colorado Health Sciences Center, Denver, CO. 80220.

CORTIS ORGAN is a quarterly publication of the American Auditory Society, processed in Dallas, Texas.

AAS Members On Cronkite's Show

On June 30, CBS aired a prime-time program on the early identification of deafness. Most of the segment was filmed at the University of Colorado Health Sciences Center in Denver and featured AAS members Jerry Northern and Marion Downs. Scenes from Lexington School for the Deaf and Albert Einstein Medical Center in New York were shown.

"Walter Cronkite's Universe" is a science magazine show that began in June, 1981. "That They Might Hear" was a special documentary on the importance of early identification of hearing loss in young children. The show featured children with hearing problems and interviews with their mothers, and demonstrated several techniques for testing the hearing of young children and infants, including BSER testing and the High Risk Register. CBS indicated "That They Might Hear" would be seen by a viewing audience of at least 30 million people.

Our Renaissance Men and Women

John Muma

(Ed. Note: Those among us who do not live by bread alone are worthy of recognizing from time to time. This will be the first in a series of such recognitions. If anyone has a favorite Renaissance person to nominate, please inform the Editors.)

John R. Muma: Ph.D., Penn. State University; Chairman, Speech Pathology and Audiology, Texas Tech University. John is both a researcher and clinician with over twenty years of clinical experience in a variety of clinical settings. He has over forty publications most notable of which are *Language Handbook* (Prentice Hall, 1978), *Muma Assessment Program* (MAP) (Natural Child Publisher, 1979), and *Language Primer* (Natural Child Publisher, 1981). He has been a keynote or featured speaker for more than 60 state or regional conventions and invited speaker at more than 45 universities. John has been active in the American Speech-Language-Hearing Association, American Psychological Association, and the Society for Research in Child Development. In ASHA, he was one of the candidates selected to be interviewed for Executive Secretary and he was in the final pool of candidates for nomination for president last year but not a nominee. He is currently organizing an Academy of Language Disorders. John has served as a reviewer for several scholarly journals and three book publishers. He has been a panel reviewer for the Office of Special Education. And, he has been very active in dealing with federal and state legislators and officials in defining and solving problems with P.L. 94-142.

John's non-professional interests include fishing, poetry, and antiques. Herewith are samples of his poetry:

POULTICE

John R. Muma
1979

She . . . in a quiet way
Knows me well
Even lying upon her breast
For that moment
I know her face
And she mine!
Our placenta dropped away
And I dropped into her sleep
And she into mine.

Leaving her behind,
My tears and hers,
I laid myself down
Upon my school rug.
And, we smiled
Even greater smiles
For both of us
Which neither saw.

She laid upon me
A warm poultice
For whatever took me
So I waked
In warm Spring morning
And she waked beside me.

Letter From England

My dear Editor,

The depressing, climatic, and social-political-economical conditions have discouraged your foreign editor from putting pen to paper. As a matter of fact he has been busy spreading the pathological gospel on the Continent and, in particular, in Belgium where he has lectured at three consecutive conferences.

ENT-pathology in common with the problems of hearing has been attracting the interest of both the general pathologist and the otolaryngologists-audiologist. This was well shown at the meeting of the British Division of the International Academy of Pathology arranged by Dr. W. Gepts, Professor of Pathology at the new University Medical School in Brussels and by the fact that the European Economic Council i.e. its subcommittee on hearing research has met, also in Brussels, under the able chairmanship of our friend Professor Salvatore Iurato from Bari to discuss a coordinated European research programme of the organ of hearing.

The third occasion for my visiting Brussels came when I was invited to take part in the Symposium on Otospongiosis of the Belgian Association of Otolaryngologists (President Dr. Freyenhoven) attended by all leading Belgian and French otolaryngologist among them Dr. Causse senior, whose theory of the lysosomal role in the pathogenesis of otospongiosis our electron microscopic studies have confirmed. Also in this country seminars and courses in our field abound and a most stimulating course at the famous Radcliffe Infirmary in Oxford arranged by Bernard Colman and his Staff has attracted many from near and far. In fact the faculty included two Americans, the ever popular Manfred McGee from Detroit and Professor R. Cotton from Cincinnati and R.E. Gristwood from Adelaide (Australia). The British contingent included many well known otolaryngologists and audiologists of our country.

Soon we shall be packing our cases for our annual pilgrimage to the Ear Research Institute recently renamed The House Ear Institute a well merited baptism.

I have begun a depressed note but the sun has come out, an American has won the Open Golf Championship in Sandwich and true sportsmanship has been displayed by winners and losers who have included some of the greatest golfers, e.g. the Golden Bear Jack Niklaus. What a contrast to the recent behaviour on the tennis courts of Wimbledon by you know who . . .

We have been worried about many more important things bearing on our future and recalling the past but, above all, we have been praying that the fruitfully-plague threatening California may soon be conquered. As Hamlet said to Horatio: 'There are more things in heaven and earth than are dreamt in your philosophy'.

Sincerely,
I. Friedmann

Editorial

The Taste of Crow

Ye editors are happily ingesting crow's meat as a result of the good turnout at the AAS meeting in New Orleans. Just two years ago we sourly complained that few otolaryngologists attended our meeting, which was also held in conjunction with the Academy that year. However, this year's attendance has been the highest yet recorded, giving the laugh to our crabbed mutterings.

Actually, the ranks were swelled largely with audiologists who were attending the Academy and were touching base with AAS in the process. There was, to be sure, a cadre of loyal otolaryngologists who left the main meetings to sit in on ours.

The gratifying aspect this year was the very tangible assistance and recognition the Academy gave us for our meeting: *Item:* The Academy assigned us a meeting place. *Item:* The Academy gave us a day for meeting within the main schedule of the Academy's program. *Item:* The Academy published our meeting time and place in the regular printed program. *Item:* In the formal procession that opened the Academy meeting this year, our president was invited to march as representative of the AAS. Ralph Naunton reported that, corny as the procession idea was, he really enjoyed it and was impressed by it.

All of these concessions give us a warm feeling for the Academy, and encourage us to seek more dialogue with the Academy and its members than with other groups. With Ralph Naunton as our marching proxy for a second term perhaps a new era of cooperation will begin. — MPD, RJR

Wanted: Poster Child Nominee for 1982

WASHINGTON, D.C., (October 15, 1981) — The Council for Better Hearing and Speech Month today invited nominations for a 1982 poster child who, along with a celebrity chairman, will represent more than 22,000,000 Americans with communicative disorder during next May's national public information campaign.

Winner of the contest will be featured in television, radio, and publication publicity, and visit the nation's capital to help launch the campaign in early May. Planned activities include a tour of the city, visits to the White House and Capitol, participation in a May 1 national special event campaign kickoff, and other special appearances.

Poster child nominees must be at least three but no older than six years old and have a significant hearing, speech, or language problem. Contestants may be sponsored by parents, friends, teachers, hearing or speech field professionals, or organizations.

To enter a child, submit his or her name; biographical information; at least two different, good-quality black and white photographs (preferably 8" x 10" glossies); a professional estimate of the degree of hearing or speech loss; and a signed photo release. Description of the child's personality, likes and dislikes, and favorite activities would also be helpful.

Mail entries to "Poster Child Contest," Council for Better Hearing and Speech Month, 1430 K Street, N.W., Suite 600, Washington, D.C. 20005. Entries must be received by the Council no later than Monday, January 4, 1982.

CITIES

John R. Muma
1970

Cities are for those
Who study subway routes
And walk fast but never at night.

Apartments are for cliffdwellers
Who don't know totem makers
Nor priests
But understand and bet
Against pro-teams.

Factories are for smoke gatherers
Who wait for and stalk
Trucks.

Crows are for those
Who measure and count
By stop-lights
Who hustler hustlers
At nonclearance sales.

Cars are for linking
Breakfast and twilight TV sets
And preparing us for cities
By emerging and purging
With starts and stops
Toots and honks
Lanes and patterns
Overpasses and underpasses
Which bypass us,
Us.

Minutes of the 1981 Executive Committee Meeting

Minutes of the American Auditory Society Executive Committee Meeting

Members Present:

Charlie D. Anderson, Marion P. Downs, A. Bruce Graham, Ed Johnson, Susanne Kos, Fred Linthicum, Ralph F. Naunton, Ross J. Roeser

Members Absent:

Susan Conway-Fithian, Malcom Graham, Earl Harford, Merle Lawrence, Sam Lybarger, Hiroshi Shimizu, John Sinclair, Dixon Ward, Laura Wilber.

- President Naunton opened the meeting at 3:30 p.m.
- The minutes of the 1980 Executive Committee meeting were presented and approved with only one spelling error correction.
- The Income and Disbursement Statement for the period of January 1, 1981 through August 31, 1981 was reviewed and discussed.
- A list of 167 applicants for membership was presented. Of this number 138 were approved, and 29 had incomplete memberships as they didn't have the necessary signatures.
- Results of the recent Executive Committee election were reviewed. A total of 403 ballots were received. The successful candidates were: Lavonne Bergstrom, Earl Harford, Susanne Kos, Bill Meyerhoff, James Nunley, Dixon Ward and Don Worthington. Those members of the Executive Committee retiring are: A. Bruce Graham, Merle Lawrence, Fred Linthicum, Samuel F. Lybarger. President Naunton expressed appreciation to the retiring officers for the effort they had expended for the Society during their terms.
- After considerable discussion, the site for the 1982 annual meeting was set for New Orleans in conjunction with the American Academy of Otolaryngology. Michael Seidemann volunteered to be the local arrangement chairman, and the names of two Executive Committee members were suggested for Program Chairman (Lavonne Bergstrom and Suzanne Kos). During the 1982 meeting an attempt will be made to have a booth for the Society.
Four individuals were identified for the Carhart Memorial Lectureship Award. President-Elect Anderson will contact the individual selected by the Executive Committee to determine if he will accept the award.
- Ross J. Roeser was appointed Secretary/Treasurer for 1983.
- Marion Downs pointed out that limiting the terms of the President to one year does not allow the President time to have an impact on the direction of the Society, and suggested that the term of the President be extended for a period of 2 years. There was a general consensus that extending the term of the President to 2 years would allow for more continuity. The bylaws limit the term of the President to one year, but do not prohibit the President from being re-elected. In view of this, with approval of President-Elect Anderson, President Naunton was re-appointed for an additional one year term for 1982.
- Ross Roeser was designated as a representative to a committee to meet with ASHA to discuss future involvement of Representative Professional Organizations. A meeting will be held on October 4, 1981 in Chicago.
- Susan Conway-Fithian recently informed President Naunton that she was unable to fulfill her duties as an Executive Committee member, and resigned from the office. The AAS bylaws do not specify how Executive Committee members are replaced. Therefore, A. Bruce Graham, whose term of office was to expire in December, 1981 was appointed to fill her vacancy. His term of office will be extended through December, 1983.
- John Sinclair, a member of the Executive Committee, did not renew his membership, and President-Elect Anderson indicated that he would contact him and determine if he wished to continue being a member of the Society. The name of an individual was suggested to replace John Sinclair if he does not wish to continue his membership in AAS.
- The Academy of Dispensing Audiologists recently contacted AAS and suggested that a joint meeting be held in 1983. After discussion it was unanimously decided that AAS not meet with ADA.

Do You Know These Applicants?

The following individuals applied for membership in AAS under the special provision and as yet do not have sponsors. If you know any of them and would like to be a sponsor, please write Susanne Kos, Assistant Secretary (1966 Inwood Road, Dallas, TX 75235).

New Members needing Sponsors

- Bui Minh Duc M.D. Walnut, Ca.
- Charles J. Baldwin, M.D. Jacksonville, Fla.
- Janet Brueck, M.A. Memphis, Tn.
- Cynthia Bagwell, M.S. Norris City, Ill.
- Bonnie L. Boehr, M.A. Pacific Palisades, Ca.
- McKay Burton, Ph.D. New Orleans, La.
- Walter Chariz, Ph.D. San Antonio, Tx.
- Stanley Cannon, M.D. Miami, Fla.
- T. Walter Carlin, Ph.D. Houston, Tx.
- Richard B. Dawson, M.D. Okla. City, Okla.
- Debra G. Dolman, B.S.E. St. Joseph, Mo.
- Georgina R. de Erdmann, M.A. Mexico City, Mex.
- Marcia Fariss, M.A. San Jose, Ca.
- M. Reese Guttman, M.D. Chicago, Ill.
- Joan Larson Glasier, M.Ed. Imola, Calif.
- Richard Hetsko, M.Ed. Oberlin, Oh.
- Harriet Green Kopp, Ph.D. San Diego, Calif.
- James Jerome, M.A. Ft. Bennington, Ga.
- Clayton R. Johnson, M.S. Dubuque, Ia.
- Jo Hanna Kingsland, Ed. Spec. Oak Park, Mich.
- Malcom H. Light, M.A. Miami, Fla.
- Ron M. Parker, Ph.D. Manhattan, Ks.
- Patricia Patton, M.S.C. Montgomery, Ala.
- James S. Payne, M.Ed. Rome, Ga.
- Thomas Moore, M.S. Calgary, Canada
- Guy O. Pfeiffer, M.D. Mattoon, Il.
- Wm. F. Strock, M.S. Medford, Or.
- R.K. Vaughan, M.C.D. San Bernadino, Ca.
- Richard B. Vaughan, Ph.D. Fresno, Ca.
- Dwayne Wildhagen, M.A. Winter Haven, Fla.

- During the 1980 AAS Executive Committee meeting the possibility of publishing a membership directory was discussed. It was estimated that the cost of publishing and mailing such a directory would be about \$2,200.00. In view of the cost, it was decided that the membership directory not be published separately but remain in *Corti's Organ*.
- The Executive Committee approved the transfer of \$1,000.00 from the AAS account to the *Ear and Hearing* account in January, 1982.
- The Editorial Board of *Ear and Hearing* recommended that in lieu of the cash award for the best papers appearing in *Ear and Hearing* in 1981, the authors of the papers receive a plaque. After discussion the Executive Committee approved this recommendation and it was further more resolved that the awards be presented during the annual meeting. In addition, the authors should be invited guests of the Society for the annual dinner.
- Ross J. Roeser expressed his appreciation to the members of the 1981 Editorial Board of *Ear and Hearing*. He also recognized the Editorial Consultants for *Ear and Hearing* during 1981. The names of the Editorial Consultants will be published in the November/December, 1981 issue of the journal.
- Marion Downs pointed out that in 1984 the International Congress of Audiology will meet in Santa Barbara, and that Sanford Gerber was the local arrangements chairman. It was the consensus of the Executive Committee that AAS should have at least a half day meeting during the International meeting and that Marion Downs should contact Dr. Gerber to begin making plans for it. Because Dixon Ward has been active in both the International Audiology Society and AAS it was felt that he should be involved in setting up the meeting.
- Ross Roeser indicated that he was looking into purchasing a computer for the Society and due to the relatively sizeable investment wanted to inform the Executive Committee.
- The Executive Committee as a group expressed its appreciation to Mike Seidemann and the other members of the program committee for their efforts in planning this year's meeting.

There being no other business the meeting was adjourned at 6:20 p.m.

AAS Statement of Income and Disbursement (1/1/81-8/31/81)

Revenues	
1. Membership dues	\$15,565.93
2. Ear & Hearing allowance	1,500.00

Bergstrom 1982 Program Chairman

LaVonne Bergstrom

Dr. LaVonne Bergstrom has accepted The Program Chairmanship for the 1982 meeting, which will be held again in New Orleans in October. A call for papers will be sent out early in the Spring. Anyone wanting information or to help with the meeting should contact:

LaVonne Bergstrom, M.D.
Div. of Head and Neck Surgery
Room 32-34 Rehab. UCLA
1000 Vetran Ave.
Los Angeles, Calif. 90024

Summaries of Papers

The Effects of Tinnitus On ABR Waveforms

Michael R. Seitz
Brooklyn College
Brooklyn, N.Y.

Dennis G. Pappas, M.D.
ECHO Foundation
Birmingham, Al.

Martha R. Mundy

Over 7 million people in the U.S. suffer from severe tinnitus and it is often the major symptom that brings patients into the otolaryngologist's office. The origin of tinnitus can be anywhere along the auditory pathway. As part of the diagnostic process, a number of patients who have complained of moderate to severe tinnitus have been evaluated with Auditory Brainstem Response Testing (ABR). During the course of this testing, patients who complained of tinnitus often had unusual as well as abnormal ABR responses. This observation was originally documented by A. Shulman, Department of Otolaryngology, SUNY, Brooklyn. He reported his results in a paper given at the Eastern Triological Society meeting (1981) using a simultaneous ABR technique.

In an effort to better understand the effects that tinnitus may have had on ABR waveforms resulting from monaural stimulation ABR responses of 45 patients previously evaluated were reassessed and compared to the following general data:

1. Patient medical history
2. Physical otological examination findings
3. Audiometric results
4. Specific ABR latency parameters that included:
 - a. Absolute latencies for Waves I, III and V
 - b. Interpeak latencies for I-V, I-III and III-V
 - c. Waveform replication
 - d. ABR evaluation - normal vs. abnormal, peripheral vs. retrocochlear

RESULTS

Initially, subjects were divided into two categories (peripheral and retrocochlear) based on their ABR evaluations. No objective or systematic response patterns were observable in the ABR latency or IPL data as waveforms ranged from completely normal to highly abnormal.

Two common findings for these patients were identified: the lack of or difficulty in replication of ABR waveforms and the presence of noise on the resulting ABR traces — that was not caused by operator or equipment problems. Four to six separate runs were often necessary before any two would replicate to an acceptable level. In addition, some ABR's displayed reduced Wave V amplitudes when compared to Waves I and III and absolute latencies from these patients often suggested sensitivity thresholds better than PTA.

Examples of aberrant waveforms will be presented and discussed in terms of the effects tinnitus might have on the evaluation of ABRs, in determining the presence or absence of pathological conditions.

Candle Snuffer Incus Replacement Prosthesis

Claude P. Hobeika,
Dorsey Ann Fleming,
Gayle P. Riemer,
Shirley E. Owens,
Cincinnati, Ohio

Several techniques have been described for reconstruction of the ossicular chain when the long process of the incus fails to make contact with the head of the stapes. Although socially adequate hearing levels have been reported immediately following surgery, long range studies indicated a gradual deterioration in the post-operative hearing levels.

The present paper describes a new technique of incus repositioning. The short process of the incus is drilled away and the incus fashioned into a "candle snuffer" prosthesis that is placed between the neck of the malleus and the head of the stapes. The patient's own incus or a homograft were used.

Thirty-two cases were selected for the studies. The follow-up period was four to six years. They all had in common, the partial or complete absence of the long process of the incus with an intact malleus and stapes. The cases were divided into two categories. One group consisted of ears with a center perforation and an ossicular discontinuity, and the other group consisted of ears with a cholesteatoma and ossicular discontinuity.

Audiological evaluations were carried out pre-operatively and at intervals of one month, three months, six months after surgery and yearly afterwards.

The post-operative air bone gap was 5 to 15dB at three months after the surgery in 97% of the cases. This remained unchanged in 91% of the cases at four and six years after the surgery.

In the ears that needed a second procedure, the repositioned incus was found at surgery to be in excellent position and transmitting motion from the malleus to the oval window.

One of the added advantages of the "candle snuffer" prosthesis is that it raises the tympanic membrane immediately below the scutum, and therefore, avoids the reformation of an attic cholesteatoma.

In summary, we feel that the "candle snuffer" prosthesis is ideal both in the short and long term follow-up for reconstruction of the ossicular chain, when the incus is partially or completely absent.

Application of the Brain Stem Arc Study to Patients with Unilateral Ear Fullness

Donrue C. Poole, and Joel F. Lehrer
Teaneck, New Jersey

Abnormalities in the latency and amplitude of the stapedial reflex (as recorded in the Brain Stem Arc Study) have been found in patients with certain vertigo syndromes.^{1,2} Findings in one hundred-fifty-four patients with such diagnoses as vestibular neuronitis, acute labyrinthitis, positional vertigo, cerebral vascular insufficiency, perilymphatic fistulas and Meniere's Disease have been reported. Patients with vestibular neuronitis, perilymphatic fistulas and cerebral vascular insufficiency were found to have the most frequent incidence of abnormalities. This evaluation has been extended to patients with unilateral ear fullness in whom there were no physical, audiologic or tympanometric abnormalities. A series of eight cases is presented in which amplitude reductions in the stapedial reflex were present on the side of the fullness. Antiserotonin therapy was associated with a return of the amplitude to normal and a relief of the symptom of fullness.

Normal studies of the latency and amplitude of the stapedial reflex as displayed by a strip recorder will be demonstrated along with abnormalities noted in patients with the above vertigo syndromes and unilateral ear fullness. Instrumentation and methods will also be presented.

Physical Characteristics and Attenuation of Foam Earplugs

Curtis R. Smith, Roy M. Broughton, Jr.,
James N. Wilmoth, Thomas E. Borton, and Ben T. Mozo
Birmingham, Alabama

Because engineering noise controls are sometimes infeasible, earplugs are considered by many as viable alternatives to protect workers hearing. Solid polymer earplugs are particularly popular for this purpose. However, a recent study showed that a solid insert earplug only 0.5mm smaller than the measured ear canal diameter effectively negates the expected attenuation of the device. None of the commercially available ear canal calibrators measure increments this small; and even if they did, providing premolded earplugs for every possible ear canal diameter is unrealistic when other alternatives are available.

Five types of foam earplugs that theoretically expand to seal the ear canal, thus eliminating the need for concern about fit, were evaluated in this study. Ten of each plug type were investigated (1) to determine the physical characteristics such as weight, length, diameter, density, expansion force, expansion pressure and chemical composition; and (2) to relate these physical characteristics to attenuation.

Expansion forces were measured to the nearest gram using an artificial ear canal designed by these investigators in conjunction with an Instron Universal tester. The other physical property measurements were made using standard equipment.

Attenuation measurements were made utilizing a Knowles Electronic Manikin for Acoustic Research (KEMAR). The results indicated that all of the commercially available form earplugs evaluated are similar in diameter, weight, and density, but were somewhat more variable in length. Although expansion force was the measurement obtained for each earplug, force per unit area (or pressure exerted against the ear canal wall) was expected to be the important variable related to attenuation. Expansion pressure was our estimate of the pressure exerted on the wall of the ear canal by the expanding foam. Both expansion force and the calculated expansion pressure were highly variable within a single manufacturer's earplugs. The chemical composition of the plugs was differentiated in terms of chlorination and water solubility.

In general, all of the hearing protectors provided greater attenuation at the higher frequencies. This finding is not new and was anticipated. At 125 Hz, the experimental plug provided significantly more attenuation than any of the other devices. Although this particular earplug provided attenuation equal to better than that of the others at all frequencies, the mean differences were not always statistically significant. Chlorination seems to have a pronounced effect on attenuation. The data indicate about 46 units of attenuation difference in residuals, after correcting for all other effects, between chlorinated (higher mean) and unchlorinated plugs.

The practical significance of these findings is that no particular earplug in our sample can be regarded simply as "better" than the others; conclusions must be drawn with reference to the earplug at each frequency.

Keith Named Program Chairman for 1983

Robert W. Keith

Robert W. Keith has already started planning for the 1983 program to be held November 17, 1983 in conjunction with the annual ASHA meeting in Cincinnati, Ohio. Program suggestions should be directed to:

Robert W. Keith, Ph.D.
Director Division of Audiology
and Speech Pathology
University of Cincinnati Medical Center

The Effects of Logon and Very Short Latency, Frequency Specific Click Stimuli on ABR Waveforms

W. Alan Eisele, Michael R. Seitz,
Martin J. McCutcheon, and Lynn F. Vranes
Birmingham, Alabama

SUMMARY

While data exists on click stimuli, tone pips and filtered clicks of various durations, little normative data exists on logons or very short duration, frequency specific clicks. The logon is a pure tone that is amplitude modulated by a gaussian distribution curve. The very short duration, frequency specific clicks were matched to the logons by frequency and duration but had a different rise-fall duration and shape. The purpose of this study was to compare logon elicited and short latency tone pip elicited ABR's from the same subject pool.

METHOD

Two separate ABR instruments were used; the Nicolet CA 1000 and the Teledyne TA 1000. The TA 1000 uses 2, 4 and 6 kHz logons as stimuli. We matched the duration of the frequency specific logons with diamond shaped tone pips generated from the CA 1000. The 2kHz tone pip was 600 microseconds in duration compared to the TA 1000 logon of 610 microseconds, the 4kHz was 400 microseconds in duration with the TA 1000 logon being 350 microseconds in duration, the 6kHz pip was 200 microseconds in duration compared to 250 microseconds for the TA 1000 logon.

Each subject (N=12, 6 males and 6 females) had hearing thresholds of better than 15dB HL for the test frequencies. The test instrument, sex of subject, frequency and ear tested were counterbalanced across all subjects. A stimulus repetition rate of 20.5 pulses per second was used for both instruments with a time base of 10 msec. Three silver-silver chloride electrodes were used with the earlobes used for reference and the vertex as active. Impedance was kept below 5000 ohms and balanced between the electrodes. Absolute latency measurements were taken from cursor outputs for Waves I, III and V at four intensities (70, 50, 30 and 10 dB nHL) for each frequency tested. Each run was the result of 2000 presentations and replicated. IPL's for I-III, I-V and III-V were also recorded for all measurable intensities.

RESULTS

Stimulus onset time was adjusted to be equal for each instrument and the data were then subjected to multivariate analyses. No significant differences in either absolute latencies or IPL's were found between the logon and tone pip stimuli. There was the anticipated significant differences in the latency-intensity functions and sex for both stimuli. There was a qualitative difference in the number of subjects who had recordable waves I and III at lower intensities for the logon stimuli. These data will be discussed in terms of the effectiveness of both stimuli to elicit ABR waveforms and their potential usefulness in clinical procedures.

Tinnitus Relief from Diet, Nutrition, Exercise, and Relaxation Techniques . . . a Clinical Study

By Paul Yanick

(Dr. Yanick was unable to attend the meeting, but readers can review the paper in print.)

This article summarizes the latest findings of a two-year long term clinical research project on patients suffering from problematic tinnitus and sensorineural hearing loss.

Since stress is often a contributing factor in many cases of problematic tinnitus, a holistic approach consisting of an individualized diet, nutrition, exercise, and stress reduction program was applied to 80 patients, ages 12-79, mean age 52, with progressive sensorineural hearing loss. Each of the 80 patients was tested before and three months after starting the holistic program. The reason for a three month follow-up is because it is the author's clinical experience that it often takes two to three months before the program actually begins to improve hearing and/or tinnitus problems.

Sixty-five or 81.2% of the eighty patients had improvements that ranged from 5-40 dB with a mean 25 dB improvement in their pure tone average (PTA) and speech reception threshold (SRT). Out of these sixty-five patients, forty-three patients also had a 6-40% (mean 30%) improvement in speech discrimination scores. Nine patients or 11.3% of the group had only slight, insignificant improvement, less than 5 dB in SRT or PTA and 6% in speech discrimination scores. Six patients or 8.6% of the group had no improvements or notable decrease in their hearing.

From these eight patients with sensorineural hearing loss, fifty patients had loud annoying tinnitus. All of these patients could not get any significant relief from tinnitus maskers and were labeled as incurable by a number of ear specialists. Most of these patients were so distressed that they discussed suicide as an eventual happening if the tinnitus did not subside.

After three months on the holistic program, forty-two patients or 84% of the fifty tinnitus sufferers reported relief in varying degrees, while only eight patients or 16% of the group claimed the tinnitus remained the same and did not change.

In the forty-two patients who reported relief, twelve patients claimed that the tinnitus was completely gone, sixteen patients claimed that the tinnitus decreased to very soft, almost unnoticeable levels and fourteen patients reported that the tinnitus decreased to not so annoying and bearable levels.

An earlier 1973-1975 clinical study on patients with hearing loss, in collaboration with an otolaryngologist associate and several internists, revealed that diet is indeed effective in providing patients with dramatic relief from tinnitus and ear pressures. This study, published in part in Journal of the American Audiology Society, revealed that ninety consecutive patients with fluctuant sensorineural hearing loss reported relief from tinnitus and ear fullness only one month after dietary management.

From the foregoing discussion, it is evident that the ear is highly dependent upon proper oxygenation and a full, not partial or mutilated, chain of nutrients for optimal sensory function. Its vulnerability, although in part is determined by genetics, is high to oxygen and nutrient deprivation. Imbalances, deficiencies, and/or excesses of certain nutrients can be expected to upset the metabolic rate and/or delicate biochemical balances of the inner ear resulting in hearing, balance, and/or tinnitus problems.

Middle Ear Effusion in Children: A Report On Treatment For 200 Patients

Brian D. Forquer,
Fred H. Linthicum, Jr.,
Otolologic Medical Group, Los Angeles

Professionals involved with delayed speech and language development have become increasingly concerned about the deleterious effects of ongoing mild conductive hearing loss secondary to middle ear effusion. Mild conductive hearing loss is known to cause significant speech and language delay in some children and subsequent reduction in academic achievement. Otolologists and pediatricians are also concerned with the occasional sequelae of unresolved otitis media including coalescing mastoiditis, central perforation and primary and secondary acquired cholesteatomas. These effects of unresolved effusion have prompted physicians to seek to minimize delay in resolution of the problem.

This study reviews results of treatment of middle ear effusion in 200 children under nine years of age. Three treatment strategies were used: 1) prescription of medications including, decongestants, antihistamines, and/or antibiotics for an extended time with frequent monitoring; 2) prescription of medication first for a short time interval, and then if the effusion did not resolve, performance of surgery; 3) immediate myringotomy with insertion of ventilation tubes and possible adenoidectomy.

Early surgical intervention resulted in significantly shorter delay in hearing restoration. It did not result in a lower recurrence rate and it did not reduce the number of occasions when thick fluid, as compared to thin fluid, was found at surgery.

(Continued from page 7)

Three children who were considered to be medical and surgical failures were fit with mild gain, low maximum power output hearing aids. In 97% of the cases reviewed, medical or surgical treatment resolved middle ear effusion in less than four months. This length of delay was considered acceptable for most children. Children with the longest histories of hearing impairment were, fortunately, the children most likely to receive immediate surgical intervention.

We feel that the child with mild conductive hearing impairment due to effusion who is a candidate for hearing aids is a rarity, and that for most children medical treatment will resolve the problem within acceptable time limits.

Relationship Between Iris Color And Nipts In Industrial Workers

Curtis R. Smith,
Thomas E. Borton,
Michael R. Seitz,
and Robert N. Kleinstein
Birmingham, Alabama

It has been hypothesized that melanin, the basic pigment found in the skin, eye, and other body organs including the cochlea, acts as part of an inner ear protective mechanism against the effects of intense noise. The color of the iris may represent one index of melanin concentration in the inner ear, and investigators have suggested that a relationship exists between both temporary and permanent noise-induced threshold shift (NIPTS) in the auditory system and iris color. The purpose of this investigation was to study the relationship between iris color and hearing threshold level (HTL) in a sample of workers exposed to hazardous levels of industrial noise.

Method

The subjects in this investigation (N=266) were textile workers ranging in age from 18 to 67 years (mean age=39.2 years) with the following demographic characteristics:

Race		Sex	
Nonwhite	White	Female	Male
24%	76%	37%	63%

The sample was divided into two groups depending upon the noise level to which they were exposed. Noise level measurements (sound pressure levels in decibels at octave bands) were made at the time of iris color determination. The control group included workers who were exposed to workplace noise levels less than 75 dBA. The experimental group included workers consistently exposed to noise levels greater than 92dBA per eight-hour work shift. The iris color of each subject was assessed using a specially constructed scale. Subjects underwent direct observation by one expert examiner to determine iris color and each was assigned to one of four color categories. HTL's for each subject were obtained using standard audiometric procedures and instrumentation calibrated to

ANSI-1969 reference levels. Pure tone thresholds for air-conducted stimuli were recorded for the frequencies 500, 1000, 2000, 3000, 4000, and 6000 Hz in each ear.

Results

Multivariate analysis techniques were utilized to examine the relationships between iris color and other variables including age, sex, race, time on the job, and HTL's. A variety of HTL indices were considered for each ear of all subjects including the following: (1) mean of all test frequencies; (2) mean of 500, 1K, and 2KHz; (3) mean of 3K, 4K, and 6KHz; (4) mean of 500, 1K, 2K, and 3KHz; (5) mean of 2K, 3K, 4K, and 6KHz; (6) maximum hearing loss at any test frequency.

Overall, the control group demonstrated significantly more sensitive hearing than the experimental group. No statistically significant relationship between iris color and HTL was observed in the control group. For the experimental subjects, a significant (p 0.002) relationship was found between iris color and HTL. One iris color group always demonstrated more sensitive hearing than any of the others, while another always demonstrated less. The remaining two groups changed order depending upon the dependent variable under consideration. Those indices emphasizing HTL's above 2KHz more consistently reflected iris color group classification than did the low frequently dominated HTL indices.

In an attempt to further define the elements of observed relationships between iris color and HTL in the noise-exposed subject group, more detailed analysis was conducted. Results revealed that while the relationship between iris color and HTL was significant, it was greatly influenced by other important variables. The relationships among all these variables will be presented, and the data will be discussed relative to their implications for industrial hearing conservation programs.

TRACOUSTICS CONTEMPORARY AUDIOLOGY WORKSHOP

One day Contemporary Audiology Workshops will be conducted in 1982 by James Jerger, PhD, Jerry Northern, PhD, and Susan Jerger, M.S. The overall test battery for both pediatric and adult audiology will be reviewed including speech audiometry, impedance and ABR. The workshops are approved by ASHA and AMA for Continuing Education credit. For further information and reservations, contact Gloria King, Professional Services Coordinator, Tracoustics, Inc., PO Box 3610, Austin, TX 78764, or call 800-531-5412. In Texas, call 512-444-1961.

Dossena Describes

CENTRO RICERCH E STUDI AMPLIFON

The AMPLIFON CENTER FOR RESEARCH AND STUDIES (C.R.S.) was founded in 1971 as a non-profit organization, solely funded by the Amplifon company.

During the first 10 years of activity, C.R.S. has fulfilled the original ambitious targets, and succeeded in enlarging its scope, and thus significance, and the practical benefits to the Italian medical profession.

During the first 10 years, 216 meetings, round tables and seminars were organized, dealing with audiology, phoniatrics, speech and hearing, noise exposure, surgery of the ear, auditory diagnosis and amplification. 185 continuing education courses in audiology, electronystagmography, impedance audiometry, phoniatrics, audiological testing techniques comprising evoked responses were attended by 3700 between medical doctors (mostly ENT's) and paramedical professionals.

In 1978 the program "the danger noise: causes, effects and remedies" was one of the first and few occasions to bring together the health authorities, the concerned industry and union representatives, the medical specialists and the governmental and regional experts, to discuss the problems of noise exposure and noise pollution, and the possible remedies. In a country such as Italy where there is no specific regulation or law, such as OSHA, the CRS program visited every one of the 20 regions; the exhibit displayed the various aspects of noise and hearing and the state of the art both in research and in effective protection and noise abatement, to all concerned and to the general public. The round tables succeeded in providing hopefully the basis for a start to a future noise protection program throughout the country.

AAS Member Ely Passes Away

Bill Ely,
Vice President
at Maico Instruments

Bill Ely, Vice President at Maico Instruments, passed away on Saturday, March 10. Bill had been a member of AAS for the past 5 years. He was an active supporter of The Society and a regular reviewer for manuscripts dealing with hearing aids for Ear and Hearing. He is survived by his wife Laurel, and his two children.

1982 Meeting On Oct. 18th To Be The Best Yet

Mike Seidemann
Local Arrangements
Chairman

La Vonne Bergstrom
1982 Program Chairman

Merle Lawrence
1982 Carhart Memorial
Lecturer

La Vonne Bergstrom, 1982 AAS Program Chairman, and Mike Seidemann, local Arrangements Chairman, are finalizing plans for the 1982 Annual Meeting of AAS, and it looks as if it will be one of the biggest and best so far.

A full days presentation of papers is planned for the October 18th meeting and the meeting will again extend into the evening hours with festive social events. This year's Carhart Memorial lecturer is Dr. Merle Lawrence; his lecture is entitled "Otologic Research and the Zeitgeist." Tracoustics has graciously agreed to sponsor a river boat tour from 6-8:00 p.m. on the well known Cottonblossom that will allow members to unwind as they tour the historic Mississippi River front. Following the river tour, those wishing to join the group can partake in a sumptuous meal at one of the most elegant French restaurants in New Orleans. Arnaud's, located in the French Quarter, is internationally known as one of the culinary delights in New Orleans. A special meal has been selected by the program committee. Featured entertainment is also being planned.

Hearing Loss In Alaska

David R. Canterbury

Presidents Message

Audiologists "take-over" the American Auditory Society

So ran the rumors at a recent national otolaryngology meeting, boding poorly for the health of an organization conceived, established and so far, kept moving by an interdisciplinary group comprising audiologists, otolaryngologists, physicists, teachers of the deaf, and others whose sole concern is the welfare of the hearing impaired. The by-laws of the Association were built to insure that no one group could "take-over", — and during its nine years of life we have had otolaryngology Presidents for five years. But Audiology is going to take over; Audiology will take the reins in hand and guide the Society; Audiology will dominate the field of auditory rehabilitation and habilitation if otolaryngology continues its present trend towards withdrawal from the Society while the Society maintains its present growth-rate, strength and influence.

The Society was established to serve the professional interests of no particular individuals other than those sharing concern for the prevention and treatment of hearing impairment, and for the rehabilitation of the hearing impaired. It was established most carefully to avoid any sense or reality that it was to undermine any existing society or association; it was established to serve an unmet need, — that of an interdisciplinary forum.

The importance of interdisciplinary liaison to the broad topic of deafness prevention, treatment and rehabilitation was dramatically illustrated by the recent International Cochlear Implant Conference held under the auspices of the New York Academy of Sciences. The faculty of this exciting conference included a breath-taking array of specialists in audiology, biomedical engineering, computer science, electrical engineering, language science, otolaryngology, pathology, physiology, rehabilitation, and speech science.

On the other hand, otolaryngologists are becoming increasingly concerned over their diminishing involvement in biomedical research, — witness another recent superb conference "Research Goals and Methods in Otolaryngology".

The time is almost past when the solidarity scientist or clinician could make palpable progress in improving disease prevention or treatment; "interdisciplinary collaboration" at all levels is the key for the future improvement of patient care.

It would be presumptuous to insist that otolaryngology needs the American Auditory Society; on the other hand, it is abundantly clear that the American Auditory Society needs Otolaryngologists if its present strength as a non-partisan professional society concerned with the welfare of the hearing-impaired is to continue.

President Ralph

We Salute Our Renaissance People

J. DONALD HARRIS

In a book review in 1976 J.D. Harris was designated as a most distinguished Renaissance Man. Herein, with a review of a new book that J.D. has just published, is further confirmation of the infinite variety of this exceptional man, who is formally being nominated as our Renaissance Person.

Editorial

Upon Retirement

As of this month Ye Senior Editor is retiring from full-time clinical work — on, presumably, to a more active life of what she laughingly calls her mind. She will work on the odd research project, write the odd book, read the odd journal, or contemplate the odd navel whenever she jolly well feels like it. The only mandatory things in life will be four tennis matches and 12 miles' running per week. An enviable schedule you will concede.

There will also be grandchildren to get to know better — where did the time go? Some of them are already college graduates; some, fortunately still young enough to stand still for a grandmotherly snuggle.

Some things remain yet to do — but may take more than this lifetime. How can we guarantee all children, regardless of socio-economic status or ethnic origin, their right to a full chance at adequate language development? Knowing what we know about the urgency of early language stimulation; knowing that too many are denied their full language potential not by Genes but by Means — what are the real priorities for those of us who know these things down deep in our inner reaches? I'm afraid to look.

Oh well — there goes my retirement. MPD

Ex-Officio:
Marion Downs, M.A.D.P.S.

Few people in the field have been as productive as J.D. Harris, both in professional activities and in avocational fields. He early saw a need for a journal that would publish papers exclusively on auditory investigations, and founded the Journal of Auditory Research. Young investigators who might not otherwise publish were encouraged by the availability of this journal to write up their research and submit it. J.D.'s careful editing and personal suggestions to the authors guided and encouraged them in their scientific endeavors.

No one person can estimate the depth of J.D.'s other interests, which we listed in 1976 as concert piano, classic literature, natural history, philosophy of art and of science. If one reads his non-audiologic books (reviewed here) one recognizes that J.D.'s overriding concern is the Study of Man and His Relationship to the Earth. Young people who are "into" some of the current movements of human ecology, increased personal awareness or international understanding, will do well to seep themselves in J.D.'s works. For here lie the great deeps of man's relationship to his environment, and contemplation of them cannot help but tap profound feelings of insight.

It is with great pleasure and not a little awe that J.D. Harris is saluted and named AAS's Renaissance Man.

Reflexions in an Herb Garden, by J. Donald and Barbara N. Harris, The Amphora Press, Box N, Groton, Connecticut 06340.

Amplifon Center For Research And Studies

The awarding ceremony to Dr. Jean Marie Aran (on the right in the picture) and to Prof. Haim Sohmer (on the left). On the centre, Ing. A. Charles Holland, President of the Amplifon Center for Research and Studies.

1981 AMPLIFON CENTER FOR RESEARCH AND STUDIES INTERNATIONAL PRIZE AWARDED IN MILAN, ITALY (Ex-aequo prize winners: Dr. Jean Marie Aran, Bordeaux University, France — Prof. Haim Sohmer, Hadassah University, Jerusalem, Israel)

The recording of auditory evoked potentials represents an extremely important breakthrough in audiology, and offers new diagnostic frontiers in the field of neurology and in the assessment of several lesions in the neural pathways and in the CNS.

Dr. Aran and Prof. Shomer were awarded the AMPLIFON CRS International Prize in Milan on March 31st, at the Press Club. The CRS prize is intended to identify, amongst researchers fighting against deafness, those whose results have proven most beneficial and, as it is in this particular case, have resulted in a clinical fall-out.

The Prize, at its 11th year, has become an international prestigious recognition, and was endowed with approximately \$4000 per researcher. (See page 1 for the history of CRS).

AAS Annual Meeting
October 18th
New Orleans, La.

Let no one assume that this book is comprised merely of nature observations in the Harris garden and descriptions of the "small wonders which abound here". For reading any book by J.D. Harris (and in this case also by his charming wife Barbara, the "Reference Librarian") is to roam at length through J.D.'s incomparable mind, sometimes even to roam through that unique collection of neurons. In a series of small essays, each inspired by some observation of flora or fauna in the garden, J.D. gently expounds on the Harris philosophy of man and nature.

The flora range from dogwood and laurel to finnel and thyme, his essay on the latter herb being titled "Thyme out of Mind". J.D. quotes Culpepper, born the year Shakespeare died, as stating about thyme, "It is a strengthener of the lungs; a good remedy for the chin-cough in children. It purges the body of phlegm, and is an excellent remedy for the shortness of breath. It kills worms in the belly, and being a notable herb of Venus, provokes the terms, gives safe and speedy delivery to women in travail, and brings away the after-birth."

J.D. comments "It is hard to see how a reasonable competent housewife could maintain her establishment without it. Expectorant, vermifuge, emmenagogue, splenetic, anodyne, and carminative, it seems in those times to have been well-nigh universal prescription. It was, however, not said to knit broken bones."

And this brings up the impressive Harris vocabulary. Someone once said upon reading J.D.'s last book "It was good reading but I just had to go to the dictionary too often". My young friend, there is no such thing as "going to the dictionary too often". Someday I hope you will understand, as J.D. does, that language is the generative fountain of the human mind, and the more we dip into it the more exalted our humanity becomes. What you should also understand about J.D.'s use of English is that he applies it as a paean of joy, and we can imagine him tasting, nuzzling, relishing each word and spouting out each one with a crescendo of Hosannas. Once you join with him in these exultations you will never be the same.

The title of the book is apt, for what the Harrises are doing truly reflecting upon what meets their eyes and assails their noses and ears. (Reflexion is an accepted spelling, reflection, and of course the pixie-ish Harris mind would prefer the former spelling.) As they state, "Should we in fact view these sights and facts with any emotion at all other than curiosity? Should we admire our hive bees because of the complex social behavior reflecting the highest development of brain in their order, or should we denigrate them because they are so stupid they cannot find their way back to the hive if it moved more than three feet left or right? Should we not rather accept all things, describing them as accurately as patient research and advanced instrumentation will allow, finding nothing repugnant in and of itself since it must have at least

Letter To The Editor

(Editor's note - The following letter and reply was sent Robert C. Cody, Associate Professor and Director of the Speech and Hearing Clinic of the West Virginia University Medical Center, Morgantown, West Virginia)

Dear Mr. Cody:

It is with shock and dismay that I have read the following excerpt from an article authored by Dr. Kenneth W. Berger in the Summer issue of *Audicibel*:

"The traditional hearing aid evaluation, modified, mangled, and maligned over many years, has served purpose historically. It has outlived its usefulness. At worst, the hearing aid comparison procedure probably permitted the clinician to discard the least effective of the preselected hearing aids. At its best, it may have done little more."

This abrupt dismissal of the traditional method of selecting hearing aids through trial by exhaustion (sometimes known as the "Russian Roulette system") has thrown confusion in the face of those of us who regard ourselves as professionals in solving the problems of the hearing impaired.

It leaves a vast vacuum and — since nature abhors a vacuum — there is danger that the result may be a profusion of competent rather than scientifically accurate fittings.

For the past three months, we have been working to find more scientifically sound system and have finally come up with a method which we call, for the sake of convenience,

(from page 1)

As a basic tool for the continuing education programs, CRS has published both basic text books in Italian and the proceedings of the meetings, round tables and international symposia. Since 1966, the CRS Notizia rio Bibliografico provides the specialist of the auditory function with a complete bibliography and summaries in Italian of all articles appearing in the world literature on the auditory function. Today, its analytical index provides over 10 thousand bibliographical notes and summaries. This service is further implemented by ad hoc bibliographical research, which, in these 10 years, has scored over 20 thousands works.

Furthermore, to promote direct interfacing with the leading researchers, CRS has organized several "tours of Italy" bringing to all the main Italian universities and medical schools invited speakers, such as

Earl Harford, in 1974
Arthur Boothroyd, in 1975
Geary McCandless, in 1977
Wolfhart Niemeyer, in 1977
Jack Vernon, in 1978
Dave Preeves, in 1981.

The CRS yearly prize, assigned to the researcher who, in the world, has most contributed to the advancement of studies on deafness and auditory impairment, has been awarded to:

1971 Tokuro Suzuki, Japan
1972 Erik Wedenberg, Sweden
1973 Hallowell Davis, U.S.A.
1974 Suzanne Borel Maisonne, France
1975 James Jerger, U.S.A.
1976 Josef J. Zwislocki, U.S.A.
1977 Michele Arslan, Italy
1978 Atore Gloria, U.S.A.
1979 Ettore Bocca, Italy
1980 Horst L. Wullstein, West Germany

The future targets for CRS broaden the area of interest to comprise neurological and communication disorders, and the sensory and motor handicaps. CRS will thus extend its services to other medical specialties, such as neurology, neurophysiology, psychiatry, intensive care and newborn medicine. Because of the impact of technological developments in these areas, as well as in the latest evolution in the auditory prosthesis and auditory evoked responses, CRS programs are enlarged to all technological and bioengineering aspects and the contributions of bioengineers has become a vital and essential part.

Considerable parts of the activities and efforts will be devoted to the research in the area of early detection of the motor, sensory and neurological handicap, as well as to aids for independent living and communication.

The first steps to this effect were taken in 1981. In June, a joint meeting with the Italian Rehabilitation Therapists Association was organized to discuss communication methods and aids for the disabled. In November an international meeting is being held to bring forward the international scenario of aids, research and rehabilitation programs, and to discuss the future trends.

As a result CRS looks forward to the constitution of some sort of a liaison group to foster international contacts for the benefit of joint efforts aiming at greater success in this extremely difficult area, which is fully underfinanced by the Italian

responsible health, education and welfare authorities.

In the past 10 years, CRS has invested in its activities, and with a progressive increase in the yearly budgets, the equivalent of 350 thousand US dollars.

CRS 1982 budget strikes for 450 thousand US dollars, thus bespeaking of Amplifon's firm will to broaden the range of activities and provide the remarkable services of CRS also to the other areas of medicine and rehabilitation. The main items in 1982 budget are:

continuing education courses	70,000
international symposia on auditory function, neurophysiology, sensory, motor rehabilitation, non vocal communication, with leading experts from all over the world	25,000
grants to ad hoc research groups, comprising trips and visits to the leading world laboratories	80,000
CRS prize	7,000
publications, text books and proceedings	43,000

This means that Amplifon is investing 1.5% of its total turnover in CRS, to provide these educational activities, that have no match within the official state and regional supports and that offer unique stimulating opportunities for the Italian medical profession.

The CRS continuing education courses are officially recognized by the Milan State University.

CRS prize committee: Antonio Antonelli, Director ENT Clinic, Brescia State University; Emanuele Biondi, Director, Bioengineering Faculty, Milan State University; Silvano Boccardi, Director, Psychiatry, Ospedale San Carlo, Milan; Marcello Cantoni, President, Italian Society for school medicine, Milan; Giuseppe Cavallazzi, Associate Professor, Speech and Hearing Institute, Milan State University; Italo De Vincentis, Director, I ENT Clinic Rome State University; Massimo Del Bo, Director, Speech and Hearing, Milan State University; Aldo Dufour, S.E.N.T. C. Besta, Institute of Neurology, Milan; Franco Ferrero, Associate Professor, Language Laboratory, Padua State University, Rome; Fabio Giaccari, Director, Speech and Hearing Institute, Florence State University; Giorgio Grisanti, Director, Speech and Hearing Institute, Palermo State University; Antonio Ottaviani, Director, II ENT Clinic, Milan State University; Giovanni Rossi, Director, Speech and Hearing Institute, Turin State University; Gino Sacerdote, former Director, Acoustics Laboratory, Turin; Carlo Sirtori, Carlo Erba Foundation; Luigi Vignolo, Associate Professor Neurology Clinic, Milan State University; Angelo Zanibelli, Amplifon.

CRS Board and Council: Antonelli, Cavallazzi, Dufour, Ferrero, Vignolo, Boccardi, Biondi, A.C. Holland, Chairman. Furthermore, the prize committee seeks advice from following international societies: Int. Society of Audiology; American Auditory Society, American Speech and Hearing Association. —Elda Dossena

Letter To The Editor

Continued from page 2

"Eeny" system. The technique is showing considerable promise and has many distinct advantages.

We recognize, however, that with our very limited means it is difficult to probe all the possible ramifications, side effects, and commercial values of the system. With the vast resources at your command, it struck us that you are uniquely capable of such exploration and we now solicit your aid.

Very briefly, the system works thusly:

On a medium sized table - one which does not exceed arms length - place a number of different hearing aids. Experience has indicated that this number should be odd rather than even - 15 rather than 16; 19 rather than 20.

To select the aid for Candidate A, the operator starts with the aid furthest to his left on the table and begins pointing at each aid in succession while chanting the old rhyme "Eeny, meeny, miny, mo." He allows one word to each aid and completes the whole rhyme. The aid designated by the final "Mo" becomes the selection.

Among the advantages we have found are:

1. **Simplicity.** No extensive educational background is required. The system can be taught to anyone over the age of three in just a few minutes.

2. **Economy.** No expensive furniture or equipment are required. It eliminates sound proofed rooms, audiometric equipment, and involved tally sheets. The only requirement is a table - although it was found desirable to provide a chair when the clinician is going to spend a significant amount of time in selecting aids for a large number of candidates.

3. **Speed.** Sixteen seconds is the average time needed by the clinician. It should be noted, however, that these studies were conducted by clinicians with a Mid-West background. It is quite possible that the selection time may increase by five or six seconds if the clinician has a Southern drawl.

At any rate, the clinician is freed from the arduous - and time consuming - task of fitting a variety of aids to the candidate and repeating an endless category of unrelated words with each one.

4. **Equity.** We have found that if we blindfold the clinician immediately after selecting the aid for candidate A and have him move the aids on the table before him with random motions before selecting one for Candidate B, then Candidate B will have a different aid when the "Eeny" formula is carried to completion.

This eliminates any possible charge of favoritism to any one manufacturer or model since - in time - every aid will have its time of selection.

5. **Improved image.** We have found that the clinician's image is much improved if the candidate is allowed to see the clinician select a large number of aids for the table but is not allowed to see the clinician go through the selection process.

The candidate is impressed with the speed at which the clinician can select the proper instrument from the vast array carried to the selection room.

6. **Candidate satisfaction.** Since it is no longer necessary for the hearing aid candidate to spend long periods of time isolated in a sound proofed booth - and since he is no longer required to respond to a seemingly endless litany of (to him) irrelevant words, we find the candidate to be less physically and mentally fatigued. He is thereby more receptive to the aid. He no longer is apprehensive that its wearing will subject him to additional suffering and actually look forward to wearing it.

7. **Accuracy of fitting.** In a study of 486 1/2* cases, it was found that the aid selected by the "Eeny, Meeny" system was more acceptable and satisfying to the user than that selected by the former Russian Roulette system.

The only difficulty we have experienced thus far with the new "Eeny, Meeny" system is some carping from the Civil

*The 1/2 case concerns a non-candidate with no hearing impairment whatever. This non-candidate had accompanied a hearing impaired friend and was so taken by wit, charm, depth of knowledge, and breadth of understanding of the clinician that she insisted on purchasing an aid anyhow.

HEARING LOSS from page 1

Unit of the Federal Alaska Native Medical Center, Indian Health Service. As has been noted in previous publications (Canterbury (1978); Kimball (1977); the amount of hearing impairment in Alaska appears to be considerably greater than found in most other parts of the United States. This higher prevalence of hearing problems is largely due to serous, acute and chronic otitis media. Noise induced hearing loss also contributes to the problem and appears to be occurring at an earlier age than was once suspected. The prevalence of chronic tympanic membrane perforations has been steadily reduced over the past decade due to the development of a village based health care system which receives backup support from centrally and regionally based ear specialists, public health nurses, physicians assistants, and audiologists. Additionally, an active surgical program has performed nearly 4,000 tympanoplasties during the past decade; Tower (1978). The existence of a productive medical component has no doubt reduced but certainly has not eliminated existence of a large number of hearing impairments as will be documented in this paper. Surgeries often leave residual hearing impairment; the surgical option is sometimes refused by the patient or is not recommended by the ear specialist, and other factors such as noise exposure also contribute to the ranks of the hearing impaired.

This article is a descriptive effort to examine the characteristics of the population served and is not an experimental design. This is being accomplished with the realization that one of the first steps in problem solving is an accurate description of the problem itself. Efforts have been made to describe and quantify the extent of hearing impairment from time to time; however, basic problems previously existed regarding commonality of terms used in describing the hearing loss and in the control of variables affecting the reliability and validity of such reports. Because of these problems, in 1976 the audiologists employed by the State and the Federal Indian Health Service programs in Alaska agreed on certain training, testing, reporting, and referral standards including the use of standard audiometric forms. Similarly, agreement was made to code these forms in a uniform manner regarding amount of hearing loss, type of hearing loss, impedance findings, referral recommendations, hearing aid use, and patient identifying information. This information is processed by an audiologic data system which provides information on a scheduled basis for client management, planning, reporting, and statistical analysis. Each year for the past 3 years from 5,900 to 10,000 entries have been made into this system. To date 32,479 audiograms have been entered on a total of 21,465 clients. The following information is an analysis of the test findings for one year, the period ending June 30, 1980 on 5,986 clients. Although many clients were seen on several occasions, only the last entry per client was used in the compilation of these data in order to avoid duplications of reporting. These are statewide data and great variability exists from region to region and, in fact, even from village to village. All audiologic testing was done by clinically certified audiologists or by nurses or technicians directly trained and supervised by certified audiologists. Equipment used was electroacoustically calibrated annually to ANSI 1969 Standards and daily biological calibration checks were done each day the test equipment was in use. Each audiogram was clinically coded by the audiologist who did the testing or by the supervising audiologist according to the detailed coding criteria which is consistently used statewide. Copies of all tests were then sent to the Central Office of the Communicative Disorders Program for inclusion in the data system.

Analysis of this information should be done with the clear realization these are not prevalence data but an examination of the various parameters of test findings obtained from clients seen in our clinics during the year. Most of the school age subjects were referred from school screening programs conducted by public health nurses, school nurses, or other school screening personnel. (Screening is done at 20db ANSI for the frequencies of 500, 1000, 2000 and 4000Hz). The failure rate for screening varied from 10.3% to 36.6% depending upon region with the more remote areas having the highest failure rate. Other referrals of children were from medical care providers or were made because of known hearing impairment. The adults were not screened routinely but were seen on self referral or on medical referral. As a consequence of the case selection process, it should be evident that this is not a random sampling of the Alaska population but is primarily made up of individuals who have been seen at our clinics with complaints of hearing problems. Such data could be compiled from the records of any busy audiologic clinic however the population served by the Alaskan programs allows comparison of native and non-native populations for the specified variables. The percentage of problems in certain categories is not as significant as is the relationship between variables such as age, race, amount of hearing loss, type of hearing loss and impedance findings. Comparisons with other similar reports

such as the Colorado study; Weber (1967), might also provide insight concerning problems unique to Alaska.

DESCRIPTION OF POPULATION

A total of 5,986 clients were seen during the reporting period ranging in age from less than 1 year to 99 years of age. The largest percentages (58.6%) were seen in

FIGURE 1

the age bracket between 2 and 19 years inclusively. Three and seven tenths percent of the children seen were under one year of age. The age breakdown is detailed in Figure 1.

Fifty-six percent of the clients seen were male and 44% were female. Race was established from the health records or by questioning the clients. Fifty-eight and nine tenths percent were Alaskan Native (Eskimo, Indian, other Native or Aleut. See Figure 2.

FIGURE 2

Clients seen during this year were from 247 different communities. Eleven and three tenths percent of the 5,986 clients were from communities with population less than 250 people, 25.4% were from villages with population of from 250-1000 people, 26.5% were from communities ranging in size from 1000-4000 and 36.8% were from towns and cities larger than 4000 people. Many rural villages are entirely Alaskan Native but the ratio of native to non-native varies widely from region to region in the state. Overall, the rural communities have a much higher percentage of natives than the urban areas and the standard of living including health care access is not comparable to the urban centers.

Significant differences were not observed between the right and left ears. Percentages on the charts below indicate the occurrence of each condition within each age group. The percentages are for the total number of ears tested within each age group.

TYPE OF HEARING LOSS

Each audiogram done during the year was coded by type of impairment for each ear. The categories were conductive, mixed, sensorineural, indeterminate and normal. Establishment of both air and bone conduction thresholds was a requirement for determining type. Inability to accomplish this task on the under 2 years of age population results in underestimation of percentage figures of type of impairment for the 0 through 4 age group. Below is a discussion of the findings in the 3 major hearing impairment type categories.

Conductive loss (A 15dB air bone gap or more at 500, 1000, 2000 or 4000Hz). Analysis of test findings confirms our clinical impression that conductive hearing loss is by far the most common finding in the 5 through 9 age group for both native and non-native groups. Twenty-two and four tenths percent of the natives tested and 15.4% of the non-natives tested were so classified, see Figure 3. The testing limitations for young children mentioned above cause underestimation of type of impairment in the 0 through 4 age group. Forty-two percent were in the indeterminate category. The impedance findings for the 0 through 2 age range are probably a better indication of the extent of pathology in the early years. Those figures are cited later in this paper. The difference in percentage is established by 5 years of age and becomes more and more prominent until age 35 when the margin between the two groups again narrows.

This inordinate number of Alaskan Natives with conductive ears at all ages is no doubt due in large degree to the lingering effects of middle ear pathology during their earlier years of life; Kaplan (1973). This is also reflective of the continuing rehabilitation efforts being directed at this group since known cases of chronic otitis media are likely to be seen on a recurring basis.

FIGURE 3

Sensorineural loss (Bone conduction loss of more than 25dB at 500, 1000, 2000 or 4000Hz). The existence of sensorineural loss of clients seen for both native and non-native populations increased progressively with age from .02% of the 0 through 4 age group to more than 50% of those over 55 years of age. (See Figure 4). Non-natives had slightly higher number of pure sensorineural problems. Many Alaskans are exposed to insurmountable amounts of high intensity noise from light aircraft, rifle fire, chain saws, snowmobiles, etc. In a separate survey done over a 4 year period; Kimball (1977), it was found that from 9 to 17% of Alaskan Natives entering high school had some degree of sensorineural impairment.

FIGURE 4

Mixed loss (Presence of both the conductive and sensorineural criteria as described above). The percentage of mixed loss impairments seen for both racial groups was quite low until age 20. Above age 20 the occurrence of mixed loss increased steadily for the natives to 25% of the clients served at age 54. The non-natives did not show similar increase with age (See Figure 5). As was shown in the above reference to pure conductive and sensorineural loss, the non-natives have a similar or higher occurrence of sensory loss, but the probability of the necessary conductive component being present in adults in order for the results to be labeled "mixed" greatly diminished. Also note that by combining the number of mixed and sensorineural losses it becomes evident that percentages of Alaskan Natives with some degree of sensory deficit (sensorineural or mixed) is more than that of the non-native population seen.

FIGURE 5

AMOUNT OF HEARING LOSS
The amount of hearing loss for each client was classified into one of six categories according to severity based upon the pure tone average (average of 500, 1000 and 2000Hz). The classifications are listed below.

Normal	PTA 15dB or less
Borderline	PTA 16dB to 25dB inclusively
Mild	PTA 26dB to 40dB inclusively
Moderate	PTA 41dB to 60dB inclusively
Severe	PTA 61dB to 80dB inclusively
Profound	PTA 81dB or more

Figure 6, 7, 8 and 9 shows the comparison of native versus non-native by age and indicate marked differences in the acuity throughout the span of ages tested. The differences between racial groups narrows with age for normal and borderline categories. The difference is slight for more severe losses until age 20. Beyond that age the margin between the groups widens substantially with the frequency of loss in natives being in excess of non-natives.

BILATERAL HEARING STATUS
The figures mentioned previously are for the total number of ears tested. It was determined that 61.2% of those with conductive losses had bilateral conductive losses. The remaining 38.8% had various combinations of conductive loss and of other types of loss. Eighty one and five tenths percent of the sensorineural losses were bilateral in nature while 53.5% of the mixed losses occurred in both ears. When level of hearing acuity was evaluated in terms of bilateral symmetry it was found that 82% of the clients with normal acuity in one ear also had normal acuity in the other. Sixty-one and seven tenths percent of the borderline (PTA 16dB to 25dB), 43.5% of mild (PTA 26dB to 40dB), 46.9% of the moderate (PTA 41dB to 60dB), 32% of the severe (PTA 61dB to 80dB) and 34.9% of the profound (PTA 81dB +) were bilateral losses of the same degree.

IMPEDANCE FINDINGS
Of the 5,986 clients seen 3,264 received impedance testing including 1,912 natives and 1,351 non-natives. Findings indicate that abnormal middle ear status was common in both young native and young non-native clients. Problems greatly subsided for the non-natives, however in the middle and upper age brackets, while the Alaskan Natives continue to demonstrate ongoing middle ear difficulties when seen for audiological evaluations and are far more likely to show at all ages test findings of large middle ear volume characteristic of tympanic membrane perforations or patent vent tube. Because of difficulty in medical followup in rural areas, vent tubes are not used as frequently with the natives as with non-natives. Results were classified according to criteria developed by Jerger; Jerger (1970), and are summarized below. (See Figure 10, 11 and 12).

DISCUSSION
The data presented in this study clearly indicates that Alaskan Natives seen in our clinics during the past year have:

1. A higher failure rate on hearing screening tests.
2. A much higher occurrence of conductive loss and

abnormal impedance findings at an early age. These conditions were also seen far more often in older Native clients than is true for non-natives.

3. A higher occurrence of sensory impairment (sensorineural and mixed).
4. A dramatically higher occurrence of mixed loss.
5. More hearing loss of every degree and substantially more individuals in the moderate to severe hearing loss categories beyond age 20.

One of the primary variables used in the study was the race of the clients served. It would however be a serious error to assume that the reason for high numbers of hearing impaired individuals who are the Alaskan Natives is solely because of race. The remote environment of many Alaskan Natives results in numerous differences in life style and health care from the urban dwelling, non-native Alaskans. Other variables which should be taken into consideration are differences in housing, nutrition, sanitation, climate and health care.

The past 7 years have been a time during which the quality and quantity of audiologic services available in Alaska have increased rapidly. The diagnostic programs for the hearing impaired are now largely in place. The next area of concern should clearly be the further development of comprehensive aural rehabilitation programs which address the needs of all ages. This effort should be closely linked to the existing clinical programs but should draw upon the resources of both the educational and health system in the state. The geography and cultural diversity of Alaska will indeed make this a challenge. Our efforts in the future will be toward this goal.

WE SALUTE from page 2

the beauty of utility, and finding everything beautiful, either sensuous because of color, form, or motion, or intellectual because it illustrates one or more of the great laws to which natural objects conform, than which nothing could be more sought for by an inquiring mind."

Occasionally the audiologist in J.D. cannot be suppressed and he launches upon a knowledgeable exposition on "Ears from Fish to Man" revealing his profound insight into the hearing process and its development. A description of how bats fine-tune their vocalizations to the limitations of their discrete hearing of a certain frequency leaves one breathless with awe.

And for those of you suffering from ennui: "A visitor sits with me for a time in our gardens, and admits being bored with the summer. Bored! With life teeming here, and everywhere, in untold profusion; with sights, properly seen, to stun the brain or engage it fully; with great questions unanswered and not even properly phrased; with a plethora of activities appropriate to the season crying to be performed which there is never enough time to do! It is as if one were to spend time at the Louvre and not be touched by the Winged Victory or the feast that awaits one, but sits in a corner and reads Mad magazine. Our task is to pry open the lid of the skull of that visitor, little by little, and pour in first a drop or two, then a dipperful, of curiosity in an effort to get some sort of meaningful exchange between our visitor and the real world, for surely nothing could be more fascinating than to explore the world in which we actually live"

After this the following invitation is irresistible: "If you are ever in the Noank area please to call and we will sweep off the patio and lay another place mat. It may be we could become fast friends. But come soon."

I for one can't wait to do so.

M.P.D.

Letter To The Editor

Continued from page 13

Rights people to the effect that the formula contains an unacceptable ethnic reference. We tried substitution of the word "Honkey", but found this to be grating on the ear and thereby aesthetically displeasing. The substitution of the phrase "Uh, oh!" for the offending word destroys the natural rhythm of the formula and sometimes results in an incorrect selection as the clinician treats the phrase as two words rather than one.

We would appreciate your comment.

Yours,
Ralph E. Hoover
Professional Hearing Center
Wheeling, WV

Answer To Hoover

Upon reading your letter of 5 October, 1979, I was also shocked and dismayed. The shock was from touching an exposed hot wire on my newly purchased HALO (Hoover Automatic Letter Opener, from a Wheeling firm of dubious reputation). The dismay was from finding you were dismayed by Ken Berger's statement. After all, haven't you been saying the same thing for many, many years and decades???

The study you conducted with the "EENY" method was certainly interesting and apparently resulted in a large number of satisfied hearing aid users. It is gratifying to me that you realize your limited means of carrying on a truly scientific study and your failure to probe all facets of the method. It is even more gratifying that you recognize my unique capabilities and resources and that you have stated, "...and we now solicit your aid."

By the word "aid," you—of course—meant my "help" and "assistance." Because, as you know, I am not now, nor have I ever been engaged in or hold an interest in any concern involved in the design, manufacture, or marketing of aids. Contrary to some people's beliefs, I am not directly associated in any manner with my wife's CODYTONE SPECIAL INSTRUMENTS COMPANY.

I must say, you have certainly come to the right person for expert assistance. My position with the university affords me the opportunity to review many proposals for more scientific methodology for fitting hearing aids. For example, I just recently reviewed a proposal which involved scattering a number of hearing aids about the floor of a motel room and having a scantily-clad young lady pick them up with her toes (called the CODY method). Another involved juggling 4-5 hearing aids from hand-to-hand and selecting the first one that fell to the floor (called the TRADITIONAL method). One ridiculous proposal involved placing 7 hearing aids, turned to Full-On gain, under a quart Mason jar and selecting whichever one "squealed the loudest" in SPL... divided by 1.7...add 8 dB for conductive losses (called the BERGER method). You couldn't possibly believe some of the more bazaar proposals I have reviewed and likewise rejected.

But, GOOD NEWS FOR YOU! Your proposal arrived at the most opportune "CODY" moment. After carefully weighing the merits of the "EENY" method to the "CODY"—my wife has pointedly expressed which she feels I should accept. You're in Luck!!! She has moved, secondly and unanimously decided that I investigate the "EENY" method!!!

We have finished the study and I will not bore you with all the finite details but, following are comments, conclusions, remarks, etc., on our replication of your "ENNY" method of hearing aid selection and fitting. We most certainly do not wish to offer an criticisms of your fine study involving 486½ subjects, however, you must realize that there were certain weaknesses in your experimental design which definitely biased your conclusions. You must always, Ralph, keep in mind that scientific research should always be left in the hands of the truly pure scientists!

The most obvious weakness in your design was that you always selected "MOE" (or its equivalent) as the aid to be fitted—thus, you violated the sacred principle of randomized sampling. So, our first task was to randomize the rhyme in the following fashion:

Each of the 8 verbal presentations were recorded in a professional radio studio using the highest quality equipment. The speakers were selected so as to represent samples of all known ethical, racial, semantical, lingual, political, regional, etc., groups. Both male and female recordings were made synchronously and simultaneously for each of the aforementioned groups.

The recorded tape cassettes were then stored in a specially designed playback machine which was computer-controlled so the person to be fitted merely spoke a few words into a microphone and the appropriate tape cassette would be selected automatically and instantly by the computer. This relieved the clinician from a lengthy search through 14,326 tapes.

First, though, in cooperation with Alleghany Airlines, we

RANDOM TABLE NUMBER FOUR

	EENY	MEENY	MINEY	MOE
EENY	1	2	3	4
MEENY	3	4	1	2
MINEY	2	3	4	1
MOE	1	2	3	4

© CODY SPECIAL INSTRUMENTS COMPANY

1. EENY MEENY MINEY MOE
2. MOE EENY MEENY MINEY
3. MINEY MOE EENY MEENY
4. MEENY MINEY MOE EENY
5. MOE MINEY MEENY EENY
6. MINEY MEENY EENY MOE
7. MEENY EENY MOE MINEY
8. EENY MOE MINEY MEENY

(Footnote: Since we are an Equal Opportunity Employer and Affirmative Action, we eliminated the remainder of the rhyme. By using just the first four words, we reduced the selection time by 74.0%.)

conducted a pilot study to see if the computer could be used to select the hearing aid rather than a human clinician. This did not work out at all!!! We threw all out hearing aids into the computer, closed the lid, plugged in the machine, turned on the power switch, and called the Fire Department! Believe you me, this was 120 times more shocking than Ken Berger's statement!!!

Thus, it became obvious even to the most wild-eyed liberal scientist that we could not eliminate the human element in hearing aid selections (with the single exception of the clinician that turned on the computer in the pilot study).

In this study, the clinician was strapped into a "spin-chair," carefully blind-folded twice (this is a double-blind study), then the chair was spun (?) around clockwise and then counter-clockwise (clinicians with digital watches could not be used) in a random fashion for about two minutes. The chair was then stopped in the position facing a table which contained the hearing aids. The aids are stored in a large, hermetically sealed, temperature-humidity controlled jar when not being used for evaluations. When the chair stops, the hearing aids are automatically poured from the jar onto the table which has a 1 3/16 inch lip around the outer edge to prevent the aids from falling off.

We certainly agree with you that it is absolutely critical that the table dimensions be such that the clinician can easily reach any point on its surface with ease. This seemed simple enough until we realized that the "reach" of our clinicians differed quite drastically. The average reach of the ten clinician's right arms was 25.6 inches; the range was 21.0 to 33.8 inches. These measurements were made by placing a yardstick in the armpit, stretching the arm out frontward on the yardstick, then reading off the length to the 1st joint of the middle finger. (The investigators were very careful to place the end of the yardstick with the little numbers in the armpit and not vice-versa!) Each clinician's reach was measured 5 times by 3 different investigators. Each arm was measured again prior to each hearing aid selection (this is called "field calibration").

Due to the very wide range of clinician reaches, a simple table would not do. A Special multi-dimensional table was designed so that all dimensions (height, width, length) would be infinitely adjustable. The prototype is computer-controlled and automatically adjusts itself for any "reach" and height by having the clinician hold his (or her) right arm straight out in front at a comfortable height for about 200 m/sec.

The equipment set-up would be as illustrated in Figure 1 (below). Notice the procedure whereby the prospective hearing aid user steps up to the wall of the HEARING AID SELECTION AND FITTING ROOM, speaks a few words into a microphone, the computer-controlled tape player selects the correct tape cassette for "EENY, etc." appropriately randomized, activates the control that spins the blindfolded clinician's chair, then plays the tape through the loudspeaker. The clinician, when the chair has stopped spinning, reaches his arm out over the table and randomly picks up a hearing aid each time a word is spoken. He does not worry about starting to either the right or the left side of the table. After spinning for

two minutes he is lucky to be able to even find the table.

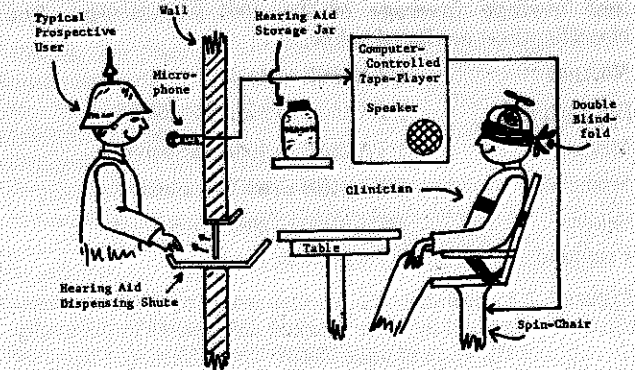

FIGURE 1: Schematic of HEARING AID SELECTION AND FITTING ROOM.

Ralph, believe me, this system has worked beautifully. We have fitted 1984 (apologies to George Orwell) hearing aids with your "EENY" method and we are completely satisfied with the preliminary results. Now, speaking of the results, we have some interesting observations to report (Figure 2).

Figure 2:

Extensive follow-up interviews were conducted with all subjects to determine if they were satisfied with their hearing aids. You will notice that those aids selected by the words "EENY" and "MEENY" provided about 90-91% satisfaction to the users. We feel this is a good percentage but can surely be improved as we further refine the procedure and design more sensitive evaluation equipment.

The "MINEY's" were, without a doubt, the most satisfied. We feel that 99% exceeds our fondest hopes and desires. Of course, we feel there may be some population bias with the "MINEY's" since the majority of our users were West Virginia coal MINERS and may have misunderstood the word. Another possible theory may be that the "MINEY's" were all very selfish, self-centered individuals and the most important word to them is "MINE"!!!

Now we come to the "MOES". We were astounded to find that 98% of the MOE's were completely unhappy with their aids. An exhaustive, in-depth interview was held with each MOE and we finally found the underlying reasons for their dissatisfaction. It is obvious that with the high cost of living, the energy crises, the nuclear power debates, the smog, severe winter warnings, high interest rates, etc., that these people just DIDN'T WANT NO MOE!!!

RECOMMENDATIONS FOR FURTHER INVESTIGATION:

From this study we have several recommendations to make for further investigation of this interesting means of selecting and fitting hearing aids.

1. Eliminate the word "MOE" from the hearing aid selection tapes.
2. Although it is tempting to use only the word — "MINEY" — to achieve 99% satisfaction, this should NOT be done because it might:

- a. adversely affect the clinician with its monotony;
- b. cause the clinician to become so self-possessive they refuse to toss the selected aid into the dispensing shute;
- c. reduce hearing aid selection to a pure science and thus upset the multitude of clinicians and dispensers who pride themselves on the "art" of the process; and
- d. cause clinicians to question the need for their extensive and expensive academic coursework, clinical practicum, and their certification and/or licensing requirements which are designed to help them make decisions between two or more entities.

We should continue using "EENY" and "MEENY" along with "MINEY." After all, if we don't have some unhappy hearing aid users we will begin wondering what we've done wrong, Right? Right!!

Thank you, Ralph, for your interesting proposal. Perhaps we could publish this reasearch jointly in order to share the fame. Our problem, of course, would be to determine whether the author credits should read: "Cody & Hoover," "Hoover and Cody," "Cody, et al." or "Hoover, et al." To settle this in a friendly manner, may I suggest you visit my research lab — we will program the hearing aid selector for the above choices and let the computer decide.

NO MOE,

Robert C. Cody

The President's Message

It is hard to believe that we are beginning our tenth year of the American Auditory Society, that it has been nine years now since Aram, Marion, Dix, Bruce, and the others organized what was then the American Audiology Society. The soundness of that planning is most certainly confirmed by the growth and recognition of the AAS here in 1982.

The very successful meeting of the Society in New Orleans on October 18th, the dedication and contribution of the key individuals who comprise the Executive Committee, and the recognition of EAR and HEARING as the ideal forum for medical audiology further proves the need for such organization and the foresight of the founders. We cannot adequately recognize the contribution which Ralph Naunton has made as President these past two years or the efforts which Ross Roeser makes to the society both as Secretary-Treasurer of the organization and as Editor of EAR and HEARING. And, let's not overlook the work done by Susanne Kos and by Sharon Roeser and by the Editorial Board throughout the year. And, someday maybe we can find a way to express our appreciation to our Number 1 flag waver and Editor of Corti's Organ, Marion Downs.

At the Executive Meeting preceding the Technical Program in New Orleans, Ross reported that membership is now up to 1147, that the Society continues on a sound financial footing, and that the quality and quantity of manuscripts submitted for publication in EAR and HEARING are very good. And, certainly we had another excellent Carhart Lecture by Merle Lawrence as well as outstanding invited and contributed papers by members.

So, where does this leave us now? I believe that it leaves us in with the obligation and opportunity to share the benefits of membership in the American Auditory Society with the Audiologists, Otolaryngologists and other hearing healthcare professionals who are not now with us. During my term as President I shall devote my efforts to the expansion of our membership to include all of those individuals who could benefit from this association.

And, I would like to count on each of you to help with this effort. Look around and see who you know that should be a member; give them an application and sign them up. You can reach me at 800-531-5412 (512-444-1961 in Alaska, Hawaii and Texas) if you need application forms or if I can be of help.

Charlie Anderson,
President, AAS

Lawrence's Address Gives Scholarly Tone To Annual Meeting

The Carhart Memorial Address of 1982 entitled "Otolitic Research and the Zeitgeist" was delivered by Merle Lawrence at the annual meeting in New Orleans. It was the most scholarly of all such presentations in that he developed the theme that it takes the accumulation of many scientific elements to come together before any particular research demonstration can be made. For example, he postulated that there were two lines of scientific thought that had to be brought to full fruition before cochlear implants could even be envisioned. The two lines were physics and morphology of the ear.

An elegant review of the backgrounds of these two lines was given, which included the history of the development of electricity through Weaver and Gray's demonstration of electrical stimulation giving rise to the acoustic effect, but it was not until the morphology of the ear was completely understood that all the elements of the Zeitgeist were together and cochlear implants could begin. He credited Simmons (1966) with the first report on implants, describing Simmons' very intense work with a subject, followed by House's and others' further experimentation on cochlear implants. Lawrence points out that speech perception has not been secured by the cochlear implants and demonstrated that the reason is that there may be only occasional dendrites or occasional ganglion cells remaining to transmit the desired message. He felt that the remaining question left to fulfill the Zeitgeist in this area is how does one stimulate the organ of Corti to produce coding of speech?

Lawrence's address will be published in EAR & HEARING. In addition to this address, a number of outstanding papers were presented at the annual meeting, most of which are abstracted in Corti's Organ this issue. (See page 9.)

Fall/Winter 1982-83

International Audiology Congress: AAS Visits Sweden, Finland and Russia

May is the month to go to Northern Europe. It is a sweet, sunny time in Sweden, Finland and Russia, as some 35 Americans found out when they attended the International Audiology Congress. Two events were appended to the Helsinki Congress: A Pre-Congress meeting in Gothenberg, Sweden, and a Post-Congress tour to Leningrad.

The Pre-Congress meeting was organized by Gunnar Liden, who heads a magnificent audiology clinic in Gothenberg. With a staff of 40 people and apparently unlimited equipment, he showed visitors an impressive facility. The program of the meeting included presentations on Electrophysiologic measures in Paedo-Audiology with many representatives from the U.S.

The International Congress of Audiology took place in the splendid Sibelius convention center in Helsinki. Dr. Tauna Palva hosted the Congress in true Finnish style, with colorful events and lavish food. The highlight of the program was a Round Table chaired and organized by Joseph Zwislöcki, on Cochlear Mechanics. The speakers, A. Flock of Sweden, D.W.

Nielson and R.G. Turner of Detroit, B.M. Johnstone of Perth and D.T. Kemp of London, presented clearly and articulately the science of the mechanics of the inner ear.

Another Round Table was presented by Francis Catlin of Houston, with Dixon Ward of Minneapolis, J. Karja of Finland, Ole Bentzen of Denmark and Marion Downs of Denver. The topic was Evaluation and Measurement of Hearing Handicap.

The focus of the International Society has been directed toward Third World problems. The new Society of Physician Audiologists is planning to establish a training center for Third World audiologists in Bad Nauheim, Germany. Funds are being solicited to carry on this school.

A tour to Leningrad climaxed the Congress for an international group of audiologists, who drove by bus and spent three days touring Leningrad. The group was awed by the vast art collection at the Hermitage, the beauty of the Summer and Winter Palaces of the Tsars, and the impressive architecture of this city of canals. (See pictures Pg. 2)

Mayor of Cincinnati Invites AAS

(Editor's Note: Chairman Robert Keith received the following invitation from Cincinnati's mayor, David S. Mann.)

Dear Dr. Keith:

As Mayor, I am privileged to invite the American Auditory Society to hold their November, 1983 meeting in Cincinnati.

Cincinnati's central geographic location, "Overnight from Everywhere", makes it an ideal city for meetings and conventions. Following a dynamic, action blueprint, our City is enthusiastically supporting a nearly completed multi-million dollar renovation of its downtown and riverfront areas. Cincinnati's residents and visitors alike mingle on Fountain Square, dine in our numerous restaurants, and shop in our vibrant, alive downtown area.

This invitation extends to your association the warm hospitality of the people of our City, and this office.

Sincerely,

David S. Mann
Mayor

Keith plans for 1983 meeting

The Executive Committee of the American Auditory Society is pleased to present 1983 AAS convention chairman Robert E. Keith. Details of the 1983 meeting will be provided in the Spring issue of Corti's Organ.

CORTT'S ORGAN is a quarterly publication of the American Auditory Society, processed in Dallas, Texas.

Letter from England

There was a successful Symposium of the Collegium Otolaryngologicum in the Hague which has attracted many members from all over the world in honour of Leonard Jongkees. He has been General Secretary of the Collegium and Professor of Otolaryngology at the University of Amsterdam. A man of great charm, a linguist and musician — he will have more time to play chamber music on his cello after his retirement later this year.

The U.S.A. were well represented by Frank Sooy, both Howard and Bill House, Hal Schuknecht, John Bordley, Merle Lawrence, Joe Hawkins, Brian McCabe, David Lim, John Snow, Bob Ruben and others adding lustre to the occasion and there were several new members from South America and Europe. The coveted Shambaugh prize was awarded to T. Palva from Helsinki, so well merited.

To mention a personal achievement, if I may, our Book (Pathology of Granulomas and Neoplasms of the Nose and Paranasal Sinuses; I. Friedmann and D.A. Osborn, Churchill Livingstone, 1982) has been well received. Regretfully, my co-author and former Colleague at the Institute has died before the publication of the book to which he has greatly contributed.

Retirement was in the air everywhere. In London an excellent Symposium on the Inner Ear was held to mark the retirement of John Ballantyne from his post as Consultant Otolaryngologist at the Royal Free Hospital Medical School. He will, of course, continue as Editor of the Journal of Laryngology which will appear in a new format in the New Year.

A great deal has been happening in our Universities and Hospitals; much of it rather depressing — but that is another story.

I. Friedmann

Gerber Appointed XV Congress President

Santa Barbara will be the scene of the next International Audiology Congress in September, 1984. To host this meeting Sandy Gerber has been appointed Congress President.

This will be the second time since 1950 that a Congress has been held in the U.S., since Aram Glorig hosted the meeting in Dallas. The job of the hosts has been greatly simplified by the decision of the Executive Committee not to require simultaneous translations. Previously translations were made in French, Spanish, Italian, and English, but by 1982 only English was required. English will be the official language of the Congress from now on. This should make it more interesting for Americans to attend in 1984!

Glorig Honored by Congress

To add to his many international honors, 1st AAS President Aram Glorig will now have his name on an annual prize being developed by International Congress individuals. A group is soliciting contributions for the Glorig Award for audiology and otologists throughout the world. Dr. Bentzen of Denmark, president of the International Society, spear-headed the drive for the Award, which in the U.S. is handled by Sandy Gerber.

Please make donations to:

Sandy Gerber with Jean Marie Aran of France.

John Peterson and Lee Urison at exhibits of Congress.

Workshops

Tracoustics Inc. of Austin, Texas is pleased to announce the schedule for Tracoustics sponsored Contemporary Audiology and ENG Workshops for 1983. These include AMA and AAS approved workshops in Contemporary Audiology and Electroneurophysiology presented at convenient locations throughout the United States.

In addition, we have announced plans for two Audiology Evoked Potential Workshops to be held in Houston, Texas in May and September of 1983. Additional information on these will be released shortly.

CONTEMPORARY AUDIOLOGY: One-day workshop in contemporary audiology presented by Dr. James Jerger. Jerry Northern and Ms. Susan Jerger covers new ideas in Speech Audiometry, Physiological Testing, Speech Diagnostic Testing in Children and the Contemporary Approach to Diagnostic Auditory Evaluation.

January 28, 1983: The Callier Center, Dallas
April 22, 1983: Loews L'Enfant Plaza Hotel, Washington, D.C.

December 2, 1982: Los Angeles

ELECTRONEUROPHYSIOLOGY: Two-day workshop in electroneurophysiology and the dizzy patient presented by Dr. Darrell L. Teter and Dr. Dennis G. Pappas covering complete review of the ENG Test Battery and interpretation of the results.

February 4-5, 1983: The Atlanta Hilton, Atlanta
May 31-June 1, 1983: Hyatt Regency on Union Square, San Francisco

September 9-10, 1983: Memphis
December 9-10, 1983: San Antonio

HIA and AARP Announce Hearing Education Program

Washington, D.C., June 22, 1982 — In a joint effort to provide information about hearing loss and hearing aids to 13.25 million older Americans, the Hearing Industries Association (HIA) and the American Association of Retired Persons (AARP) announce the development of an educational outreach program. Entitled "Have You Heard?: Hearing Loss and Aging," the program will include an automated, 33-mm slide/tape presentation, a group leader's manual and consumer materials about hearing loss and hearing aids. To be distributed through AARP's national network, the program will be promoted for use at AARP's 5,000 community-based chapters and other community groups throughout the United States.

This joint effort is part of AARP's Health Advocacy Services and a component of HIA's comprehensive Market Development Program.

In announcing the program, AARP Senior Program Coordinator, William C. McMorran, and HIA President William A. Austin, noted that "this is an unprecedented opportunity for our associations to bring hearing health awareness to the segment of the American population with the greatest incidence

of hearing loss. Our objective is to provide useful information about the identification, correction, and treatment of hearing problems for this age group." Both McMorran and Austin emphasized the importance of this endeavor, as individuals 65 years and older represent nearly 62% of America's 22,000,000 hearing impaired citizens.

"Have You Heard?: Hearing Loss and Aging" is scheduled for distribution by September, 1982. The multi-media program will be promoted through the publications of both associations and AARP pharmacies throughout the country. The complete kit will be available, on loan at no charge, for older adult groups wishing to conduct this educational program on hearing loss.

The content of the program was reviewed and approved by a joint AARP/HIA advisory committee which met in Duluth, Minnesota, on June 21. The committee is co-chaired by Carl Hofland, Assistant State Director of the AARP in Minnesota, and Marjorie D. Skafte, Editor & Publisher of Hearing Instruments magazine. Ms. Skafte is also the Chairman of HIA's Market Development Committee and the Association's Secretary.

The American Association of Retired Persons is a nonprofit, nonpartisan organization dedicated to helping older Americans achieve retirement lives of independence, dignity and purpose.

Founded in 1958 by the late Dr. Ethel Percy Andrus, AARP is today the nation's largest organization of older Americans, with a membership of more than 13 million. Membership is open to anyone age 55 or older, whether retired or not.

AARP's motto is "to serve, not to be served." Members give meaning to that motto through active involvement in community, state and national affairs.

The Hearing Industries Association represents firms which manufacture or distribute hearing health care products or their component parts. As a major focus of the association, HIA conducts a market development program which is designed to increase the appropriate use of hearing aids by individuals with hearing losses. In addition, HIA publishes and distributes publications for physicians, technical professionals and the public on amplification and the proper use of hearing aids.

Midwinter Research Meeting

The annual Midwinter Research Meeting of the Association for Research in Otolaryngology will be held January 24-26, 1983 at the Dolphin Beach Resort in St. Petersburg Beach, Florida. In addition to contributed papers, symposia are planned on the chemosenses and developmental and comparative aspects of speech production and reception. People wishing to register should contact Donald W. Nielson, Ph.D., Secretary-Treasurer, Association for Research in Otolaryngology, Otological Research Laboratories, 7036 E&R Building, Henry Ford Hospital, Detroit, Michigan 48202.

Audio 83 Hyatt Regency

First tri-annual conference on audiology and neuro-audiology. Program includes basic physiology, current and proposed techniques of audiologic evaluation, and introduction of pathology profiles using a new strategic format and electronic audience response system. Concurrent otology meeting.

Audiological Resource Association Meeting

The Audiological Resource Association held its summer meeting in Savannah, Georgia, May 15-16, 1982. Dr. Dan Schumaier, Watauga Hearing Conservation, Inc. Johnson City, Tennessee, presented an informative lecture on Industrial Hearing Conservation. Dr. Schumaier has a long-standing program of hearing conservation within his area. He shared many of the practical aspects of noise survey analysis, engineering and administrative controls, audiometric testing, ear protection and educational programs for employees. He further presented procedures for contacting industries to plan programs which would reduce occupational noise induced hearing loss among our employees, meet state and federal regulations regarding industrial noise, and obviate any medical/legal problems developing from hearing impairment. Finally, he discussed the Occupational Safety and Health Act, pointing out new regulations and the requirements for meeting these roles.

Ms. Faye M. Churchill, Brookwood Hearing and Speech Clinic, Birmingham, Alabama, gave a very informative presentation on current methods and research in extended high frequency testing. As part of her presentation, she introduced and displayed the Demlar model 20 K extended high frequency audiometer. This unit provides capability for hearing assessment from 8,000 to 20,000 Hz. Information gained from testing in this range can assist in the ability to predict hearing loss in the speech frequencies and to determine the effects of ototoxic drugs. Ms. Churchill pointed out that the addition of this audiometer makes it feasible to expand and up-grade the scope of hearing and speech services at a low cost and pre-

sents an unprecedented opportunity to assist a larger clientele with new audiometric techniques thus, advancing the goals of the audiology profession. Furthermore, research by Dr. Charles Berlin in Kresge Hearing Research Laboratory indicates that in some types of hearing loss it is critical to be fully aware of the amount of residual high frequency hearing before an adequate amplification system can be provided. This information, of course, can only be obtained through the use of extended high frequency audiometry.

In addition to attending the informative meeting, the members enjoyed historic Savannah and its friendly residents. The association looks forward to the October meeting in Wintergreen, Virginia where Dr. Jerry Northern will be the guest speaker, discussing pediatric audiology and impedance testing. This meeting will be open to all interested individuals, and students are encouraged to attend. Information about the association or the fall meeting may be obtained by writing the ARA secretary, Ms. Faye Churchill, Suite 402, 2022 Brookwood Medical Center Drive, Birmingham, Alabama 35209.

OTO 83 Hyatt Regency

Third tri-annual conference on otology, neuro-otology and laser microsurgical techniques. Format integrates basic science with practical surgical and medical therapy using a comprehensive syllabus, electronic audience response system and illustrated technique tricks. CME Credit: 24 Hours Category I. Concurrent audiology meeting. Program Director: Rodney Perkins, MD.

"Prof. Stelio Crifo" International Prize

In memory of its former President, Prof. Stelio Crifo, the Italian Audiology Society has instituted an international prize of 5 million lire (approximately 4000 U.S. dollars). This prize will be awarded on 26 October 1983 during the XVIII National Congress in Rome.

The prize will be awarded to unpublished research carried out by a single worker (or a joint work) that makes a truly positive contribution to any one of the following subjects:

Applied acoustic physics - Psycho-acoustic - Embryology of the auditory system - Microscopic or ultrastructural anatomy of the auditory system - Biochemistry or histochemistry of the auditory system - Physiology or electrophysiology of the auditory system - Experimental or clinical deafness - Diagnosis of deafness - Medical treatment of deafness - Surgical treatment of deafness - Prosthetic treatment of deafness.

The papers must be written in English.

Entries will only be accepted from persons aged 35 or under on 26 October 1983.

Each paper must be identified by a pseudonym and sent in 6 copies to reach the following address:

Prof. Giovanni Rossi
Head, Department of Audiology
3, via Genova - 10126 Torino (Italy)

not later than 30 June 1983.

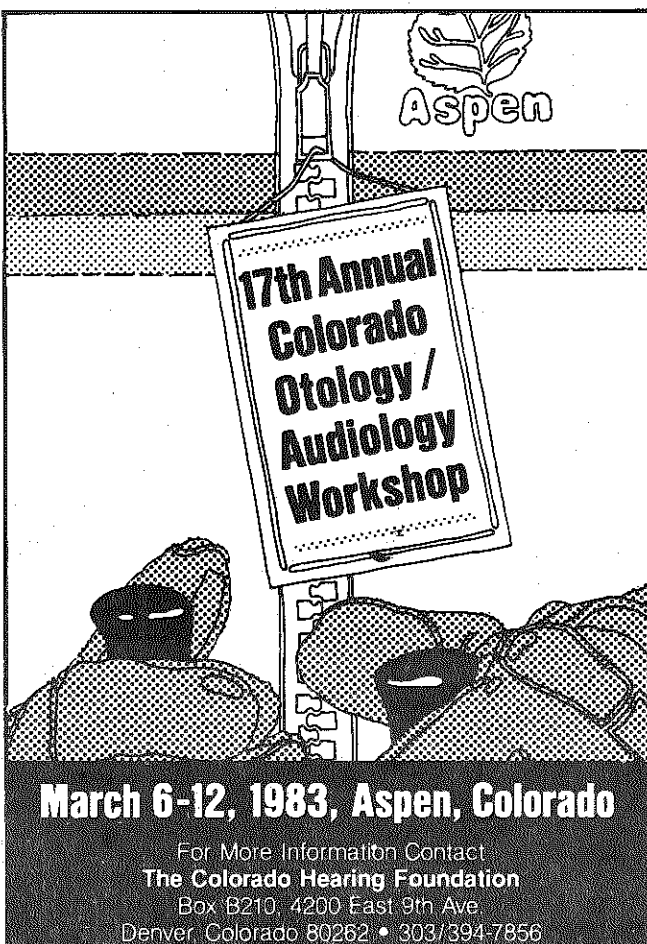

Each paper must be accompanied by a sealed envelope bearing the pseudonym identifying the work. This envelope must contain the first name, the surname and the address of the author(s) and an official document showing the age (s) of the author (s).

The Jury will be composed by the following persons:
Prof. G. Rossi (Turin), Chairman; Prof. J.C. Ballantyne (London); Prof. B. Calogero (Naples); Prof. M. Del Bo (Milan); Prof. F. Giaccari (Florence); Prof. G. Grisanti (Palermo); Prof. G. Motta (Naples); Prof. C.R. Pfaltz (Basle); Prof. M. Portmann (Bordeaux); Prof. A. Quaranta (Bari); Prof. H.F. Schuknecht (Boston); Prof. J. Tonndorf (New York).

Each member of the Jury shall supply the Chairman not later than 15 September 1983 with a list of three papers in order of merit. Three points will be assigned to the first choice, two to the second and one to the third. The prize will be awarded to the research so scoring the highest number of points.

In the event of a tie the prize will be divided equally among the winning papers.

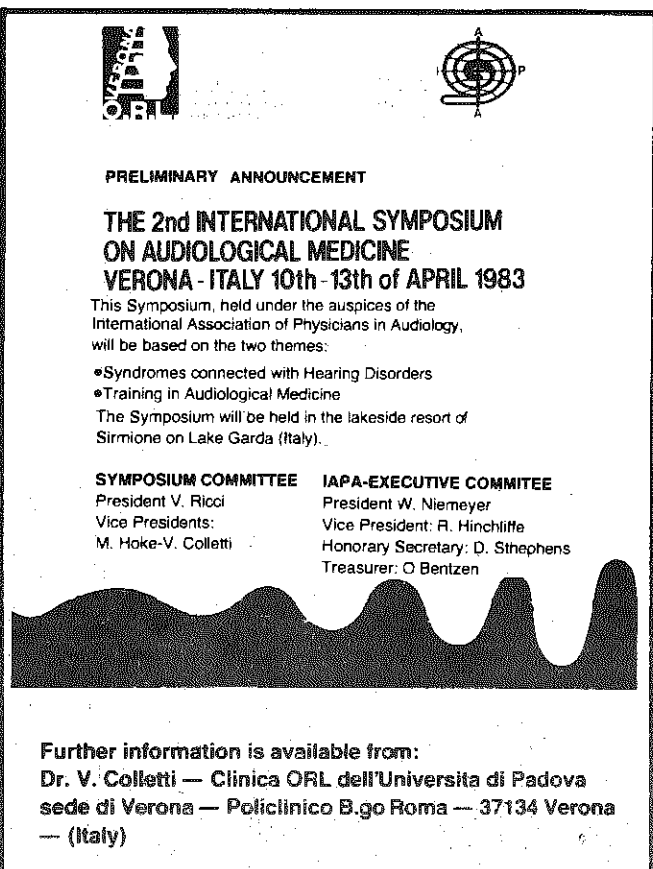

Prof. Giovanni Rossi
President of the Italian Audiology Society

PRELIMINARY ANNOUNCEMENT

THE 2nd INTERNATIONAL SYMPOSIUM ON AUDIOLOGICAL MEDICINE
VERONA - ITALY 10th - 13th of APRIL 1983

This Symposium, held under the auspices of the International Association of Physicians in Audiology, will be based on the two themes:

- Syndromes connected with Hearing Disorders
- Training in Audiological Medicine

The Symposium will be held in the lakeside resort of Sirmione on Lake Garda (Italy).

Ear & Hearing Editorial Board Meeting

DATE: October 17, 1982

PLACE: L.S.U. Speech & Hearing Clinic, New Orleans, LA
MEMBERS IN ATTENDANCE: Irvin Gerling, Deborah Hayes, Robert W. Keith, Ross J. Roeser, Eugene Sheeley, Bruce Weber

MEMBERS ABSENT: Philip Bellefleur and William Meyerhoff

1. The meeting began at 10:00 a.m.

2. The changes for the 1983 (Volume IV) Editorial Board were announced. The 1982 Section Editors will remain the same, but three Editors will be added. Mrs. Eleanor Goodspeed will serve as the Managing Editor. In this capacity she will handle the day-to-day operations of the journal, including logging in manuscripts, following manuscripts, and taking care of problems with the editorial flow of manuscripts. Dr. Deborah Hayes will be the Section Editor for a section on Speech Audiometry. Dr. Hiroshi Shimizu will be the Section Editor for a section on Hearing Science. The addition of the hearing science section changes the philosophy of the journal somewhat in that this section will review papers that are not necessarily clinical in nature. However, the addition of this section reflects the broader philosophy of the American Auditory Society. This Section will allow basic hearing scientists to publish their data in the journal.

3. The special issues for 1983 will include issues on Pediatrics, to be published in January/February (Dr. Laszlo Stein, Guest Editor), and Dichotic Listening (Dr. Robert W. Keith, Guest Editor), to be published in November/December. Suggestions for future special issues include: an issue on topics in otolaryngology, vestibular function, digital processing in hearing aids, genetics of hearing loss, and speech audiometry. A 75 page supplement will be distributed to the readers of the journal on the effects of unilateral hearing loss. Dr. Fred Bass is the Editor of this supplement. It is the summary of findings obtained on a grant and will be paid for out of grant funds.

4. At the 1981 meeting the possibility of having survey papers was discussed. A survey paper was defined as a paper that would review the past five to six years of literature on specific topics, and/or present relevant clinical information on a specific topic. Two survey papers are presently in the editorial review process. One on the pitfalls in ABR audiometry by Dr. Bruce Weber and the other on the physiological aspects of sensorineural hearing loss by Drs. Salvi, Hammernick, Henderson, and Ahroon. It was suggested that other topics for survey papers might include temporal aspects of the acoustic reflex, neuroradiological techniques, Meniere's Disease, and cochlear emissions.

5. The procedures for identifying outstanding articles for the 1981 issue resulted in five papers being selected. After reviewing the process, it was felt that it was equitable and a similar process would be followed for articles appearing in the 1982 Journal. Deborah Hayes wanted to go on record that she opposes the concept of giving awards for outstanding articles.

6. Mr. Ken Startt, Business Manager for the Williams and Wilkins Co., presented information to the Editorial Board regarding the Journal. First and foremost was information that the journal was becoming financially sound and the future looks good. Prior to 1980, the Journal of the American Auditory Society had lost approximately \$42,000. In 1980 Ear and Hearing lost an additional \$22,000, primarily due to development, but in 1981 a turnaround was seen and a loss of only \$477.00 was seen. In 1982, the Journal is expected to turn a profit for the first time, earning about \$5,000. Beginning 1983 there will be a design change that will use slightly smaller type and will save approximately 10% of space. This 10% will generate approximately 30 more printed pages of material within the present page allotment.

7. Following Ken Startt's presentation each Section Editor gave a report on his Section.

Phillip Bellefleur had written a letter to the Section Editors to be read. The essence of his letter was that he is not getting enough material to give audiologists the information that he feels is adequate. He suggested the possibility of doing a reader survey. Although he felt that his section would rate low with regard to the number of papers submitted, he felt that is an important section and should be continued.

After reviewing Dr. Bellefleur's letter the Editorial Board felt that he should personally encourage his colleagues to submit their work to the journal in an effort to bolster the number of manuscripts submitted. This would probably be the most expeditious way of generating material.

Irvin Gerling reported that his primary responsibility is to provide full support to the editor in any capacity deemed appropriate by the editor. He also indicated that his goal continues to be to reduce costs and that there is concrete data suggesting that his work has been successful, as the recent financial report indicated that redaction costs were being reduced as compared to previous reports. In addition, minor style changes have been initiated with the objective of increasing readability and optimizing Journal space.

Robert W. Keith reviewed the manuscripts he had received in the past year, since the Editorial Board met. He indicated that he has reviewed approximately 26 manuscripts and that his acceptance rate is about 46%. The type of manuscript he has been receiving has been different than at first, in that he is

now receiving more manuscripts that are truly clinical. Ross Roeser pointed out that by far Dr. Keith has the greatest volume of manuscripts.

William L. Meyerhoff (was not present at the Editor's meeting, but reported later at the Editorial Committee Meeting) indicated that his problem was manuscripts had been submitted in Otolaryngology during the year. It was suggested that he solicit manuscripts from his colleagues in order to bolster the flow of manuscripts. In addition, a special issue on otolaryngology should help to identify the journal to the otolaryngological community as the place to publish their work.

Eugene Sheeley provided a summary of book reviews Volumes I-III. It is quite apparent that the number of reviews has increased over the past three years and the addition of the "Noted in Brief" and "New and Forthcoming" sections have generated a great deal of information of interest. Dr. Sheeley also suggested sending out a style manual to the Editorial Board.

Bruce Weber reviewed the process by which he handles reviews for his section. It was indicated that he is now sending each manuscript out to three readers, as there are instances of only getting one review back when reviewers are selected.

Ross Roeser expressed his deep appreciation to the Section Editors for their continued support in working on the Journal. A discussion was held regarding the general review process for each section. It was stated that each Section Editor handles specific details somewhat differently, but there is general uniformity in handling reviews. In instances the reviewer is anonymous, but the author is known to the reviewer(s). Although some question was raised regarding the appropriateness of this procedure, the general consensus was that it was acceptable. It was also suggested that 2-3 months should be the target for completing the review process.

9. It was agreed that an Editorial Board meeting will be held during the ASHA meeting in Cincinnati in 1983. There being no further business, the meeting was adjourned at 12:25 p.m.

Ross J. Roeser, Ph.D.
 Editor-In-Chief

**COMING SOON-THE 1983
 AAS MEMBERSHIP DIRECTORY**

Minutes of the AAS Executive Committee Meeting

DATE: October 17, 1982

PLACE: L.S.U. Speech & Hearing Clinic, New Orleans, LA
TIME: 1:30 p.m.

MEMBERS PRESENT: Charlie D. Anderson, LaVonne Bergstrom, Marion P. Downs, A. Bruce Graham, Ed Johnson, Susanne Kos, William Meyerhoff, Ralph F. Naunton, James Nunley, Ross J. Roeser, Hiroshi Shimizu, W. Dixon Ward, Don Worthington.

MEMBERS ABSENT: Malcolm Graham, Earl Harford
GUESTS: Irvin Gerling (Editorial Assistant-Ear & Hearing), Michael Seidemann (local arrangements chairman), Ken Startt (Business Manager, The Williams & Wilkins Co.), and Bruce Weber (Section Editor-Ear & Hearing).

1. President Naunton opened the meeting at 1:30 P.M.

2. The minutes of the 1981 Executive Committee Meeting were reviewed and approved with no corrections.

3. The Income and Disbursement Statement for the period January 1, 1982 through September 30, 1982 was reviewed and discussed.

4. A list of 230 applicants for membership was presented and sponsors for those applicants not previously having sponsors were provided. All applicants were approved for membership. This list will be published in the next issue of Corti's Organ. (See pg. 8).

5. The site for the 1983 Annual Meeting was confirmed and plans for the meeting were reviewed. Dr. Robert W. Keith is the Program Chairman and has already secured the meeting room and made arrangements for the dinner. A letter from the Mayor of Cincinnati was circulated to the Committee. It was suggested that J. Donald Harris be the Carhart Memorial lecturer. President Anderson will contact Dr. Harris to

request his acceptance of the award.

6. Considerable discussion was held regarding the 1984 meeting. One possibility is to meet with the 17th International Congress of Audiology, to be held August 26-30 in Santa Barbara, California. Dr. Sanford E. Gerber had written requesting AAS to hold its meeting in conjunction with the Congress, but the specific details were unknown. That is, it was not known what time would be allotted to AAS, whether or not a separate admission fee could be charged, whether AAS would be requested to provide financial support to the International Congress, etc. The other possibility would be to hold the annual meeting in conjunction with the AAO-HNS, as it is presently scheduled.

Some concern was voiced over holding the AAS meeting with the International Congress, as registration fees usually are approximately \$200. This, it was felt, would eliminate many of the AAS members from attending. Concern was also raised regarding having the meeting with AAO-HNS, as it is only two or three weeks after the International Congress Meeting and members attending the Congress might not be able to attend the AAS meeting due to their close proximity in time. It was decided that Ross Roeser would contact Sandy Gerber and discuss the specifics of holding the 1984 AAS meeting with the International Congress. Once the details are worked out, a decision will be made by the Program Committee.

7. Ross Roeser was appointed Secretary/Treasurer for 1984. By vote of the Executive Committee his allowance was set at \$150 per month.

8. Susanne Kos was appointed Assistant Secretary/Treasurer for 1984.

9. At the 1981 meeting of the Executive Committee a motion was passed to retain Ralph Naunton as President for a second

term. The reason for extending the term was to allow President more time to have an impact on the direction of the Society. In accordance with the spirit of this motion, the Executive Committee agreed to reappoint Dr. Naunton for one year following the first year he served in Office of President. Along similar lines, it was agreed that the term of President, beginning with president Anderson's term, will extend from Annual Meeting to Annual Meeting. President Anderson will assume Office October 19, 1982, and will retain his Office until the 1984 Annual Meeting.

10. A membership drive was held during July, August, and September, 1982. Brochures were sent to approximately 6000 ASHA certified audiologists. To date, 108 new members have been generated as a result of this effort. It was decided that future efforts will be directed at otolaryngologists and educators of the deaf. It was suggested that rather than sending brochures to all 6000 members of the AAO-HNS, interest groups should be considered first. Specific interest groups that were mentioned included: The American Auditory Society, The Neurotology Society, The Academy of Otolaryngology, and The Society of University Otolaryngologists. Charlie Anderson pointed out that the company will be sending a mailing to Otolaryngologists in the near future and indicated that it may be possible to include information in this mailing. It was decided that Dr. Naunton would compose a letter to the Otolaryngologists which would be signed by Drs. Meyerhoff and Roeser, pointing out the benefits of membership in the American Auditory Society, and this would be included with the 11. The American Speech-Language-Hearing Association (ASHA) Related Professional Organization (RPO) Meeting was held in the Summer of 1981, resulted in guidelines for the future.

(cont.)

Meeting of AAS

(cont. from p. 4)

were reviewed by the Executive Committee. Generally, these guidelines allow RPO's such as AAS an opportunity to be identified within the ASHA structure and hold meetings during the annual meeting of ASHA. It appears as if they will permit AAS to schedule its meeting in a more organized fashion when it meets with ASHA in the future.

12. A report was given on Ear and Hearing. Ross Roeser reviewed the highlights of the Editorial Board Meeting that was held several hours before the Executive Committee Meeting. Three members will be added to the Editorial Board. Eleanor Goodspeed will be the Managing Editor, Deborah Hayes will be the Section Editor for Speech Audiometry, and Hiroshi Shimizu will be the Section Editor for the Hearing Science Section. Special issues planned for 1983 are Pediatrics (January/February) and Dichotic Listening (November/December). A supplement will be circulated to the readers on The Effects of Unilateral Hearing Loss. Dr. Fred Bess will be the Editor.

Mr. Ken Startt, Business Manager for Williams and Wilkins, presented information to the Executive Committee. Financially, the Journal made a turnaround in 1981. In that year the Journal lost \$477.00, making the total indebtedness approximately \$63,000. For 1982, the Journal is expecting to turn a profit for the first time. If forecasts are accurate the Journal will earn approximately \$4500.00. For 1982, if forecasts are accurate the Journal will earn approximately \$11,000.00. There will also be a design change in the format that will save space. Basically, the size of the type will be reduced.

Ross Roeser also requested that \$1000.00 be transferred from the AAS account to the Ear and Hearing account, as it has been done for the past two years.

13. Marion Downs reported on Corti's Organ. She asked whether or not there was any objection to publishing the newsletter 2 or 3 times per year as has been done in 1981 and 1982. There was no objection to this.

14. A nominating committee was formed to replace seven members of the Executive Committee. Those members being replaced are: Charlie D. Anderson, Bruce Graham (appointed replacement for Susan Conway-Fithian), Malcolm Graham, Ed Johnson, Ralph Naunton, Hiroshi Shimizu, and John Sinclair. The nominating committee appointed was: Don Worthington (Chairman), Hiroshi Shimizu, Jim Nunley, and William Meyerhoff.

15. The point was raised that the American Auditory Society does not have standing committees. Thus, many times certain activities that should be carried out by the Society are overlooked. Based on this, it was decided that a committee on committees be formed, with Ralph Naunton as the Chairman. Dr. Naunton was given the responsibility of appointing chairmen of standing committees that would deal with certain issues of the Society. Examples of committees included a Membership Committee, Professional Relations Committee, Program Committee, and Credentials Committee. Dr. Naunton will report on his recommendations at a later date through written correspondence.

16. Don Worthington was appointed Vice President/President Elect. Due to the change in the term of the President, Dr. Worthington will assume this position for the remainder of 1982, 1983, and until the annual meeting in 1984, at which time he will become President from 1984 through 1986.

17. The ASHA long range planning committee had written to

inform AAS of its existence. It is expected that AAS will be contacted in the future to input that committee.

There being no further business the meeting was adjourned at 5:20 p.m.

Ralph F. Naunton, M.D.
President

Ross J. Roeser, Ph.D.
Secretary/Treasurer

NOISE-CON 83 TO BE HELD AT MIT

"Quieting the Noise Source" will be the theme of NOISE-CON 83, the 1983 National Conference on Noise Control Engineering. NOISE-CON 83 will be sponsored jointly by the Institute of Noise Control Engineering and the Massachusetts Institute of Technology.

To be held on 21-23 March 1983 on the MIT campus, NOISE-CON 83 will emphasize a physical understanding of noise generation and noise reduction at the source.

NOISE-CON 83 is the sixth in a series of national conferences on noise control engineering devoted to specialized topics in the field. Other conferences have been held jointly with the National Bureau of Standards, the NASA Langley Research Center, Purdue University and the North Carolina State University.

For further information on NOISE-CON 83, contact the Institute of Noise Control Engineering, P.O. Box 3206 Arlington Branch, Poughkeepsie, NY 12603, U.S.A.

Tympanometry and Fistula Test

by Bernard Causse, J. Bel and Jean R. Causse

Otology Clinic
34325 BEZIERS—France

ABSTRACT

"Fistula test" is a major cause which may lead to an erroneous diagnosis in tympanometry testing, particularly after stapedectomy for otosclerotic stapedia fixation. In fact, fistula test is conducted when an abnormal opening between the vestibule of the inner ear and the middle ear cavity is suspected, either after a trauma or after stapedectomy. Tympanometry, recorded on ENG tracing, frequently shows a fistula sign after a correct stapedectomy, without any fistula. No less frequent is the absence of a fistula sign in the case of perilymph fistula.

The authors explain the reasons for this paradoxical response in tympanometry testing and draw the conclusions from this apparent abnormality.

Fistula sign is very well known and has been, since HENNEBERT described it in 1911 (1). The detection of this sign is extremely helpful in the diagnosis of labyrinth hydrops of medical origin and of perilymph fistula which may occur as a complication of stapedectomy. In both cases, the commonest symptoms are fluctuating hearing loss, tinnitus, a feeling of fullness inside the ear, and imbalance or vertigo. After stapedectomy, it is of the greatest importance to determine in the event of such symptoms whether they are to be related to the failure of the operation itself or to an eventual labyrinthine fluid hyperpressure. For the leakage of perilymph from the vestibule of the inner ear into the middle ear cavity after stapedectomy is a serious complication which may lead to a profound and irreversible cochlear loss and even to a risk of meningitis, if the perilymph fistula is not immediately detected and if a revision operation is not performed urgently. For this reason, the best choice must be made at once: either medical treatment or surgery according to the diagnosis.

For a long time the detection of perilymph fistula has been difficult because of the lack of efficient and reliable testing methods. In fact, to detect this condition, Valsalva maneuver, tragal compression and pneumatic otoscopy were previously considered helpful in the diagnosis of fistula in combination with the search of nystagmus and Romberg testing, but of these, only pneumatic otoscopy proved to be reliable, whereas Valsalva maneuver and tragal compression

are too often inconclusive. A useful improvement in the detection of fistula sign has been afforded by the combination of Impedance Bridge measurement and Electronystagmography, introduced to make the fistula test more sensitive and more accurate (2,3).

FISTULA TEST USING IMPEDANCE BRIDGE AND ELECTRONYSTAGMOGRAPHY

The results of ENG in the early detection of the presence of perilymph fistula have been so inconsistent that many authors have tried to find a more reliable method (2,3,4,5,6,7,8,9). Even when performed with care, routine vestibular tests may reveal a direction-fixed positional nystagmus or a canal paresis, rarely a spontaneous nystagmus, but these findings cannot always be relied upon as a certitude of a fistula (2,3,5). And the "ENG fistula test, using impedance bridge for pressure change and electronystagmography to aid the establishment of nystagmus and dizziness" was presented by DASPIT, CHURCHILL and LINTHICUM (2) in January 1979, as "a quick and reliable procedure", whereas in September 1978 (6), we ourselves were far less enthusiastic about the safety of this test, which "may lead to an erroneous diagnosis" (6,7,8,9). Such a difference of opinion is certainly based on a number of conditions which deserve to be investigated.

1/ Test procedures were similar. ENG recordings were made with a six-channel R.A.C.I.A. system 74 Model CFDP 77, equipped with a preamplifier PRT 74 C. Recording speed was 15 mm/sec. Calibration was standardized to 10 mm deflection on the recorder for 10 degrees of eye deviation. Electrodes were placed for recording horizontal (CC) and vertical (AC) nystagmus in accordance with the Geneva agreement. All examinations were made with closed eyelids, even at the time of the investigation for rotatory nystagmus, since we can record the horizontal and vertical nystagmus thanks to two channels.

The fistula test was elicited by means of the MADSEN Model Z073 Impedance Bridge, after having checked the patient for spontaneous nystagmus by recording and having asked him to inform us as soon as he felt any imbalance or condition similar to his symptoms. Pressure was progressively increased to +400 mm H₂O, held at this level for approximately 20 seconds and then gradually decreased to -400 mm H₂O, maintained at this level for 20 seconds, and finally brought back to zero rapidly. An ENG recording was made throughout this procedure, which was repeated three times,

unless the patient experienced dizziness or vertigo. In case, the procedure was performed on both the suspect and the non-suspect ears. The elicited nystagmus may be (positive test) or absent (negative test) either on only one or on both positive and negative pressure, or on both positive and negative pressure (Fig. 1). Neither accident nor incident has ever been caused by this procedure, even in ears previously operated by stapedectomy. In this study, we only selected and accounted significant tracings, and rejected questionable tracings such as those altered by artifacts.

2/ Subjects. This number was inevitably restricted by the fact that our otology clinic is specialized in otosclerosis, and to a lesser extent in Meniere's disease. Our consultants have rarely to examine patients suffering from post-trauma or post-otorrhea sequelae. Moreover, the use of a living tissue graft for stapedectomies (teflon-valve technique, originated by one of us (10 to 18) greatly reduced the number of postoperative perilymph fistula. Finally, certain cases were eliminated from this study because of incomplete history or the lack of sufficient investigation. Thus, of 65 cases were selected in this study, ranging from January 1970, date of the first tympanometry for detecting fistula, till the end of 1981. The control-group was constituted of 25 normal subjects without any history of vertigo or surgery and 10 post-stapedectomy ears (Tab.I).

3/ Test results. Our findings were so various that a systematization was difficult to establish, but we can summarize them as follows:

a) All ENG fistula tests elicited by tympanometry were negative on normal subjects.

b) There was no correlation between symptoms, ENG findings, caloric responses and ENG fistula test. Some patients with surgically confirmed fistula had normal ENG findings, but patients suffering from vertigo or imbalance usually showed modifications to their ENG tracing showing either abnormally reduced responses or no response at all. Likewise, some patients, whose symptoms started when blowing the

Group Develops Standards For ABR

—H. Shimizu

In February of 1982 a group of clinicians and scientists representing diversity of backgrounds (Neurology, Audiology, Otolaryngology, Pediatrics, Electroencephalography) met together in Laguna Beach California, under the auspices of the Department of Neurology, University of California, San Diego, to consider recommendations for standardizing auditory brainstem response testing. In some areas it was easy to reach an agreement that standards are not yet possible at the present time. There were other areas where the consensus was that more information and further consideration would be required. The proceedings of the conference will be published by Sensus, Amplaid Scientific Publications, Milano.

A summary of our conclusions follows:

I) Scope

It was agreed that we would try to define the requirements for the equipment, and also conventional communication including nomenclature. We would not discuss only limited aspects of testing protocols as these would be very much in flux. We would not consider the requirements for technicians or interpretation of the results; these latter issues are the proper domain of the professional National Societies.

II) The ABR as a neurological test for brainstem assessment

Stimulus: Clicks are to be used, produced by a square wave pulse applied to an earphone with a flat frequency spectrum such as a TDH 49 or equivalent. Equipment should allow presentation of either single clicks (condensation or rarefaction) or alternating clicks, and also broad band noise to the contralateral ear for masking.

Intensity: A range of intensities in 5 dB steps up to peak equivalent SPL should be available. The intensity of clicks should be acoustically calibrated twice a year using a standard coupler and sound level meter. Intensity should be stated as "dB peak equivalent SPL."

Rate: Stimulus rates should be available from 1 to 10 per second.

Electrodes: Electrodes of relatively equal impedance should be applied to the scalp in the midline between the vertex and forehead and on the ear mastoid ipsilateral to the ear stimulated. The

Tympanometry

(cont. from p.6)

had normal caloric responses and a questionably positive ENG fistula test. In one patient, fistula testing elicited strong nystagmus only on negative pressure.

c) The ratio of positive and negative ENG-fistula tests to positive and negative surgically confirmed cases is not so obvious in our series as the conclusions of DASPIT, CHURCHILL and LINTHICUM, evidenced in accordance with their series (2). Our findings showed that, out of 37 positive tests, only 18 were surgically confirmed and there was no fistula in 16 positive tests, whereas out of 28 negative tests, 12 fistula were found at the time of revision operation performed because of a strongly suggestive history of fistula. Negative ENG tests only corresponded to negative revision-operations at a ratio of 28 to 14, that is in the proportion of only 50% (Tab. I), far below the generally admitted percentages. We first assumed that it was a matter of a run of bad series, but the following findings were even more impressive.

d) Out of 10 stapedectomized patients, tested as a part of the control-group at the time of an audiometric check-up 6 months or more after the operation, 7 showed a positive ENG-fistula sign with any symptom of imbalance or vertigo and with a perfectly stable hearing functional result. All these 10 patients have been operated on by stapedectomy using the "teflon interposition technique", that is a small hole in the footplate and a teflon piston against a vein graft (10 to 18) (Tab. I).

These findings lead us to a possible explanation of such a great discrepancy between the test results, obtained by different authors (2,6,7,8,9,19 to 28), particularly those of DASPIT et al. (2) and our own (6,7,8,9).

COMMENTS

In order to find the explanation of these surprisingly contrasting results, we analyzed the most typical cases, 4 of which are reported below:

Case 1 (N 783162): a 41-year-old woman, who had previous stapedectomy on the right ear in 1967, complained of fullness and roaring, profound deafness in the operated ear and vertigo immediately after the operation. She experienced repeated episodes of dizziness, particularly at the time of nose and throat infection caused by colds, which led her to consult us. Romberg test was positive. Audiometric check-up showed a profound perceptive hearing loss on the right ear and normal hearing on the left ear. No spontaneous nystagmus. Torsion swing test revealed mild vestibular paresis on the right ear and 50% reduced response was demonstrated on right caloric testing. Gentle tragal compression and Valsalva manoeuvre only caused brief dizziness, without nystagmus, when the pressure change occurred on the right ear. ENG-fistula testing, repeated on two separate test dates, was negative on both ears, apart from when the pressure change from positive to negative occurred in the right ear. Surgery revealed a wide fistula around the shaft of the teflon-piston. The prosthesis was removed and the oval window sealed with a vein graft, without any replacement of the prosthesis. Dizziness and tinnitus progressively disappeared after surgery, but hearing evidently did not recover. The patient declined tragal compression and Valsalva, but surprisingly, ENG fistula test on the right ear was positive at the time of the third month control whereas it remained negative on the left ear, not operated on.

Case 2 (N 18439): a 56-year-old woman was operated on both ears in 1961 and 1962 with a satisfactory functional result in accordance with the poor cochlear reserve of stage III. Nine years after the left stapedectomy, the patient experienced a progressive sensorineural hearing loss on this ear, with occurrence of tinnitus and imbalance. In 1974, repeated episodes of dizziness led the patient to enter our clinic for full examination. Pure tone audiogram revealed severe discrimination loss on the left ear. The functional result obtained on the right ear remained unchanged. There was no spontaneous nystagmus, but positional nystagmus showed right beating nystagmus. Torsion swing test and caloric testing revealed reduced vestibular responses. Pneumatic otoscopy and Valsalva manoeuvre were negative. ENG fistula testing from +400 mm H₂O to -400 mm H₂O on the left ear established a mild nystagmus and the patient experiences slight dizziness. Surgery revealed a large perilymph fistula, constituted by a wide hole in the center of the vein graft, half closed by the fibrous tissue filling the inside of the polyethylene strut. The prosthesis was removed and the oval window covered with a vein graft, without any prosthesis. The patient has had no dizziness since surgery. Postoperative ENG fistula test was negative. Hearing levels have not improved.

Case 3 (N. 762175): A 47-year-old woman underwent previous stapedectomy on the right ear in 1968 in Italy, with a subsequent perforation of the tympanic membrane and persistent airborne gap. Two revision operations were performed.

First in 1976, a myringoplasty in order to close the perforation, — second in 1977, a stapedectomy on middle ear fibrosis and thick obliterative otosclerosis of the oval niche. The functional result was satisfactory for two years, but an otitis caused both an opening of the ABG and a sensorineural hearing loss in 1979, in spite of an adequate treatment. The progressive occurrence of tinnitus and dizziness and the persistence of the ABG + sensorineural hearing loss led us to consider performing a revision-operation. There was no spontaneous nystagmus, but positional testing showed dizziness and left beating nystagmus when suspect ear was downwards. Tragal compression and Valsalva manoeuvre were positive. Caloric testing demonstrated strong nystagmus and a great deal of subjective dizziness on both positive and negative pressures. Surgery revealed a considerable fibrosis of the middle ear cavity and a narrow perilymph fistula with a probably vestibulo-fibrosis because of the production of nystagmus by traction on the fibrous tissue invaginated into the narrow tunnel remaining from the previous fenestration of the obliterative otosclerotic stapedia involvement. The procedure using a vein graft covering the niche without any prosthesis led to a progressive relief of the dizziness and to some improvement of the hearing level. Postoperative ENG fistula test was slightly positive. A secondary sensorineural hearing loss arose two years after the revision operation, probably due to vestibulo-fibrosis.

Case 4 (N degrees 31887): A 61-year-old woman had previous stapedectomy in 1972 on the right ear, and in 1974 on the left ear with a satisfactory functional result on both ears. In 1976 she suddenly evidenced tinnitus and fullness in the left ear, dizziness, then vertigo, and finally a progressive sensorineural hearing loss in the left ear. ENG fistula test was strongly positive, as well as tragal compression, but the Valsalva manoeuvre was negative. As the patient had had Meniere's history and as the appropriate treatment cleared both symptoms and sensorineural hearing loss, a revision-operation was postponed. Repeated episodes of dizziness and sensorineural hearing loss in the left ear in spite of carefully observed treatment, led us to perform a revision-operation. ENG fistula testing on the left ear was positive, as well as tragal compression. Caloric testing showed a 50 percent reduced vestibular response on the left ear, and within normal limits on the right. Revision-operation did not reveal any fistula: the vein graft had neither dehiscence nor hole; it was supple. The teflon-piston shaft was well centered without adhesive fibrous tissue, and its length was well suited: 4mm25. The manipulation of the prosthesis produced neither dizziness nor nystagmus. At the time of the last checkup, eight months after the left revision-operation, the ENG fistula test remained positive. In short, we can say that surgical findings failed to confirm the diagnosis of perilymph fistula established by the positive ENG fistula test and the follow-up has been in favour of Meniere's disease of vascular origin. Only the suppleness of the vein graft covering the wide footplate fenestration can explain the positive ENG fistula sign, as it probably did in 7 out of the 10 normal stapedectomized ears taken as a part of the control-group.

In summary, the first case concerns a wide perilymph fistula, following upon a teflon-piston stapedectomy, with a negative ENG fistula test before the revision-operation and slightly positive after. The second case is that of a large fistula caused by a polythene strut, but half closed by the fibrous tissue overgrown inside the tube, with a slight response at the ENG fistula testing before the revision-operation and disappearing after. The third case shows a strongly positive ENG fistula test, related to a narrow perilymph fistula and probable enhanced by vestibulo-fibrosis, with a slightly positive ENG fistula test remaining after the revision-operation. The fourth case is demonstrative of a thoroughly positive ENG fistula test without any perilymph fistula at the revision-operation and with the same positive response after this revision; this case is closely related to the positive response in the postoperative testing of stapedectomized ears with satisfactory functional result and without any fistula (Tab. II).

These four typical cases, selected as representative of the wide range of the 65 cases reported in this study, as well as seven cases of the control-group (out of the total of 10), have the same common denominator, that is the inverse ratio of ENG fistula test positivity to the size of the perilymph fistula: the smaller the perilymph fistula, the more positive the ENG fistula test response.

EXPLANATION OF TYMPANOMETRY RESULTS IN PERILYMPH FISTULA

In accordance with the various findings reported above, which led us to formulate the rule of an inverse ratio of ENG fistula testing response to the size of perilymph fistula, we do believe that the reasons for this condition are clear (Fig. 2).

1/ In the case of a fistula, the changes of pressure produced by tympanometry from +400 to -400mm H₂O do not lead to corresponding pressure changes in the vestibule of the inner ear as the perilymph leaks through the fistula. If a stapedectomy has been already performed, perilymph leaks

around the shaft of the prosthesis into the middle ear when the pressure is positive. But the reversal of the pressure to negative may lead to bad side-effects by the introduction of mucus or atmospheric air into the vestibule. This is shown in Figure 2, explaining why a real perilymph fistula may not be expressed by a positive response at ENG fistula testing by tympanometry.

Thus it is quite conceivable that the leak of perilymph through the fistula (and around the prosthesis shaft if the ear has been operated upon), is in direct ratio to the size of the fistula. Therefore the response of the ENG fistula test elicited by tympanometry, depends on the size of the perilymph fistula, allowing a greater or lesser leak of perilymph, since the positive response is caused by the alternating hyper and hypopressures into the vestibule of the inner ear, produced by changes in pressures into the middle ear cavity. The greater the size of the fistula, the greater the leakage of perilymph, and thus the lesser the response of the ENG fistula test. Consequently the positivity of the ENG fistula test response is in inverse ratio to the size of the perilymph fistula (Tab. III).

These conditions easily explain the discrepancies in the results obtained by the authors who tried to find a reliable and safe test for the early detection of perilymph fistula (6, 7, 8, 9, and 19 to 28), particularly DASPIT et al. (2), whose case 8, concerning a negative ENG fistula test after a Cody tac procedure, was an enigma. These authors anticipated a positive test result "on the theory that the footplate would be displaced medially," whereas the perilymph leak and thus the negative response to the test, can in fact be explained by the fistula created by the tack. Moreover the destruction of the labyrinthine structures by the tack, could have prevented any ENG response.

2/ After a normal stapedectomy, the supple thin vein graft covering the oval window niche, and all the more the very thin membrane sealing the oval window after other types of surgery, allow the changes of pressure produced by tympanometry testing, to compress and decompress the labyrinthine fluids (Fig. 2). The positivity of the ENG fistula test after a satisfactory stapedectomy, depends in direct ratio on the size of the footplate fenestration performed by the surgeon. A total stapedectomy leads to a greater response than a small hole technique. These effects are the opposite of those encountered in the case of a perilymph fistula, because changes in pressure are totally transmitted to the vestibule of the inner ear, without any leak of perilymph, thanks to the suppleness of the graft or of the mucosa covering the footplate fenestration.

In summary, the alternating positive and negative pressures produced by tympanometry and recorded on ENG tracing, may show a fistula sign after a satisfactory stapedectomy without any fistula, whereas the response to ENG fistula testing by tympanometry may be negative in the case of a real perilymph fistula. (Fig. 2)

CONCLUSION

The "ENG fistula test", elicited by tympanometry and recorded on an ENG tracing, is a procedure of choice allowing an early detection of perilymph fistula. But the responses to this test must be interpreted in the light of the mechanical exchanges of pressure between the middle ear cavity and the vestibule of the inner ear. The responses strictly depend on the anatomical conditions existing on the site of these exchanges. The study of the perilymph fistula, easiest to investigate at the level of the oval window after stapedectomy, allowed us to schematize the various responses according to the size of the fistula and the seal of the window. The positivity of ENG fistula test, elicited by tympanometry, is: 2/ in case of fistula, in inverse ratio to the size of the perilymph fistula; - 2/ after stapedectomy, in direct ratio to the size of the footplate fenestration.

Interpreted in this way, the "ENG fistula test" produced by tympanometry is a valuable addition to the battery of the tests allowing an early detection of perilymph fistula, i.e. caloric tests, tragal compression, Valsalva's manoeuvre, pneumatic otoscopy, which are of lesser value. Only the combination of these tests can lead to an accurate diagnosis.

But one must keep in mind that an early tympanotomy is the only safe means of assuring the diagnosis in case of doubt and of allowing us to be in time to reverse the severe side-effects of perilymph fistula by means of an immediate revision-operation.

RESEARCH ON PATHOGENESIS OF CHOLESTEATOMA: IMPLICATIONS FOR TREATMENT

M. Abramson
H. Moriyama
Y. Shirahata and
C.C. Huang

Department of Otolaryngology,
Columbia University, New York

Two of the biological features of cholesteatoma namely progressive, unrestrained skin growth and localized bone resorption have been the subject of several recent studies in our laboratory and in others. Although the understanding of the pathogenesis of cholesteatoma is still far from complete, what is known does have important therapeutic implications in a disease that causes significant hearing loss and often requires repeated operations for surgical extirpation.

Clinical studies have demonstrated the importance of negative middle ear pressure in the early stage of cholesteatoma development. Animal experiments in our laboratory and in others have shown that factors favoring skin growth include availability of blood supply, the presence of inflammation as well as compression and confinement of skin. These factors help explain the particular difficulty presented by children with cholesteatoma who have eustachian tube dysfunction, frequent otitis media, pneumatized temporal bones with numerous bony defects and crevices. Factors enhancing skin growth should be considered in forming a rational treatment plan in children and others with eustachian tube malfunction and pneumatized mastoids. Consideration of pathogenic factors help explain why retraction pockets occurring in childhood evolve into cholesteatoma many years later. Preventive treatment is both rational and indicated in certain cases of retraction pockets.

The second important feature of cholesteatoma is the occurrence of subadjacent bone resorption. Bone resorbing factors present in chronically inflamed connective tissue of cholesteatoma explain the potential for resorption. However, compression as well as factors present in epidermis and its products appear to play an exacerbating enhancing role in the bone resorption process.

These pathogenic factors in bone resorption have important implications in certain therapeutic problems including whether or not to leave the matrix over a semicircular canal fistula, whether to leave the canal up or down in mastoid surgery as well as the possible future role for medical treatment in cholesteatoma.

HEARING LOSS IN HUNTER SYNDROME — MUCOPOLYSACCHARIDOSIS II

James E. Peck,
University of Mississippi Medical Center

Hunter syndrome (Mucopolysaccharidosis II) is a genetic, metabolic disease of excessive mucopolysaccharide storage leading to mental and skeletal abnormalities, distinctive facial features and increase prevalence of hearing loss. However, the hearing impairment in MPS II has not been well described in the literature. This paper examines the auditory aspects of MPS II by reviewing the literature and by presenting two affected brothers. Each subject had mixed hearing disorders, fluctuating between moderate and severe degrees associated with recurrent middle ear effusions. Hearing loss appears to be a frequent concomitant of MPS II and may be conductive, sensorineural or mixed. The conductive component may persist after myringotomy. Aggressive audiological and otologic management are required to enhance communicative development.

SODIUM FLORIDE — EFFECTIVENESS OF TREATMENT FOR OTOSCLEROSIS

F. Linthicum, B. Forquer
Otolological Medical Group Inc., Los Angeles

Otosclerosis causes a progressive sensorineural hearing loss in many patients with this disease. This progression is caused by an active otospongiotic process in the bone surrounding the cochlea. We have treated patients with cochlear otosclerosis or stapedial otosclerosis who show marked progression of the sensorineural component, with sodium fluoride for just over 10 years. It is believed that sodium fluoride changes otospongiosis into its product — otosclerosis. This transformation arrests the deleterious effect of the active disease process.

Effectiveness of sodium fluoride in arresting progression of sensorineural hearing loss was examined in 98 patients with confirmed stapedial otosclerosis and 94 patients with cochlear otosclerosis. The rates of progression before treatment were also compared to control groups of 100 patients each. Duration of observation ranged from 3 to 25 years before treatment and 3 to 14 years after treatment.

In 63% of patients with cochlear otosclerosis and 46% of patients with stapedial otosclerosis, progression of loss was arrested entirely or the rate was slowed markedly. Some patients, however, did show increase in progression. 20 different variables were then examined to try to determine whether certain patients were more likely to respond positively to treatment. Sex, type of surgery, and type of otosclerosis (cochlear or stapedial) were all statistically significant variables. Males, and patients with cochlear otosclerosis had much more successful results overall. Also, patients who had stapes mobilization surgery responded poorly to sodium fluoride therapy.

In certain patients, then, sodium fluoride does positively affect progression of sensorineural hearing loss in otosclerosis.

"MONITORING OF AUDITORY BRAINSTEM RESPONSES DURING ACOUSTIC TUMOR SURGERY"

Connie Jordan
Rodney Perkins
Darcy Benson
John Winstead

California Ear Institute, Palo Alto, California

Auditory brainstem responses were obtained pre-operatively, intra-operatively, and post-operatively in 12 procedures of acoustic tumor removal by laser vaporization. Data were analyzed with regard to morphology, latency, and amplitude. Dynamic changes in the responses which occurred during the surgical procedure will be discussed. Specific measurement variables and the viability of the technique as a routine monitoring procedure will be addressed.

CHILDHOOD OTITIS MEDIA AFFECTS DEVELOPMENT OF WORD, BUT NOT SENTENCE, INTELLIGIBILITY

Susan Jerger, Baylor College of Medicine

The purpose of this study was to determine how recurrent conductive hearing loss due to otitis media may influence the development of speech intelligibility performance for both words and sentences. Subjects were 25 normal children and 25 children with recurrent otitis media. Ages ranged from 24-56 months. At the time of testing, all 50 children had normal hearing sensitivity on both ears. All children passed a neurologic screening test for developmental normalcy.

Speech intelligibility performance was assessed with the Pediatric Speech Intelligibility (PSI) test. Individual data were performance — intensity (PI) functions for PSI word and sentence materials in isolation and in the presence of a competing message. The message to competition ratio (MCR) was constant across intensity levels: 0 dB for sentences and +4 dB for words. Different MCR test conditions for sentences and words were selected to equate performance for the two different types of speech materials in normal children between 3 and 6 years old.

Individual maximum scores of the PSI-PI functions were used to construct developmental functions (average performance as a function of age) for word and sentence materials in isolation and in competition. In the normal control group, developmental functions showed two salient features. First, performance in isolation was relatively better than performance in competition.

With increasing age, performance in isolation reached a 90-100% correct level approximately 6 months before performance in competition. Second, performance in competition was relatively better for words than for sentences. With the exception of results at the "floor" and "ceiling" of the developmental functions, performance for words was about 10-20% better than sentence performance. These two features of PSI development functions in normal children were reminiscent of results of diagnostic speech audiometry in adults with CNS auditory disorders.

In the otitis media group, developmental functions were normal for both words and sentences in isolation and for sentences in competition. However, developmental functions were grossly abnormal for words in competition. For example, with increasing age from 24-30 months, performance for words in competition improved about 60% in the normal group, but only about 10% in the otitis media group.

The difference between groups may be highlighted by comparing the percent of children in each group achieving an arbitrarily defined criterion score of at least 80% correct performance. Performance for PSI sentence materials in competition reached the criterion score in 52% of the normal group and in 53% of the otitis media group. In contrast,

performance for PSI words in competition met the criterion score in 72% of the normal group, but in only 29% of the otitis media group.

In short, recurrent conductive hearing loss appears to be associated with abnormalities in the growth of word understanding in competition in some children. (Colleagues on this study were James Jerger, Ph.D.; Bobby R. Alford, M.D.; and Sue Abrams, M.S.)

EVALUATION OF SUB-CLINICAL EIGHTH NERVE DYSFUNCTION IN LEARNING DISABLED CHILDREN

S. Thomas Westerman
Hahnemann Medical College, Pennsylvania
Liane M. Gilbert
Otolologic Education, Inc.
Shrewsbury, N.J.
Linda Gray Madusky
Otolologic Education, Inc.
Shrewsbury, N.J.

Researchers such as Kephart, Ayres, deQuiros and others have found that defects in the balancing mechanism contribute significantly to learning disabilities in children and adults. Disturbances in auditory areas also decrease the child's ability to function in the classroom. Many of these defects are sub-clinical in nature and therefore difficult to detect. A battery of tests was developed for evaluation of sub-clinical defects of eighth nerve origin. These tests include assessment of vestibular function related to balance, visual-vestibular perception, positional maintenance and evaluation of auditory figure ground (ability to screen out non-essential noise from essential elements of sound) abilities.

132 school aged children diagnosed as learning disabled by a child study team were evaluated using these procedures. 94% had abnormal findings on vestibular function testing. Of those 94%, 86% revealed unilateral hypofunction, 62% had optokinetic, pendular tracking, and/or positional maintenance deficits, and 32% had a combination of vestibular disorders. 21% had spontaneous nystagmus on positional testing. 22% of the children had auditory figure ground perceptual impairments.

Children who revealed hypofunction of the vestibular system were treated with therapeutic dosages of meclizine HCL and/or dyphenhydramine hydrochloride. Those who demonstrated deficits on the optokinetic or pendular tracking tasks were treated with a combination of phenobarbital and scopolamine. Children who demonstrated a combination of disorders were treated with a combination of the above drugs. Those who had deficits in auditory figure ground testing were referred to the child study team for development of the proper educational plan.

Subjects were monitored closely on a monthly basis to observe the effects of the medication. Areas of weakness were retested at 6 months and 1 year. 6 month observation revealed improvement in 79% of children treated for hypofunction of the vestibular system based on the battery of tests. 65% of the children with vestibular hypofunction showed from moderate to marked improvement in academic abilities according to respective child study teams at this interval. Medication was terminated. After re-examination in 1 month, 11 children were placed on medication due to the recurrence of vestibular dysfunction. Progress is presently being monitored.

51% of children demonstrating visual vestibular defects and/or positional maintenance difficulties showed improvement at 6 month testing. Child study team reports indicated that 35% of these children showed from moderate to marked improvement. 71% had improved by the 1 year testing interval.

Based on these findings, it is suggested that this testing should be included in the evaluation procedures conducted by child study teams for the purpose of devising the proper educational plan.

NEUROAUDIOLOGICAL TRENDS IN SPLIT-BRAIN SUBJECTS AND THEIR RELATIONSHIP TO CHILDREN WITH AUDITORY PROCESSING DIFFICULTIES

Frank E. Musiek,
Dartmouth Medical School
Hanover, N.H.

It has been shown that subjects who have undergone complete, one-state commissurotomy demonstrate specific trends on certain central auditory tests. Among these are severe left ear deficit (for verbal report) on dichotic speech tasks and poor auditory pattern perception bilaterally for

(cont. on p. 10)

Abstracts

(cont. from p. 9)

verbal report, but normal performance for humming these patterns. Also, these subjects perform normally on monaural low redundancy speech (i.e. low pass filtered speech, speech in white noise, etc.) and auditory fusion tasks.

In our investigations on children with auditory processing difficulties we have found some perform in a manner similar to split-brain subjects. Generally, these children do not demonstrate as severe effects as the split-brain subjects, but an obvious relationship seems to exist. It has been noted that approximately 20-25% of the children investigated for auditory processing dysfunction demonstrate this "split-brain effect". These findings have compelled us to theoretically entertain the possibility of abnormal auditory inter-hemispheric interaction in children who demonstrate this specific type of neuro-auditory profile.

Several audiological case studies showing relationships between split-brain subjects and children with auditory processing deficits will be discussed.

HEARING AID USERS AND MUSIC: A SURVEY OF LISTENING HABITS AND ATTITUDES

J. Richard Franks (Presenter)
Washington State University
Pullman, WA

Teresa Hall
Yakima Ear, Nose, and Throat Clinic
Yakima, WA

Although extensive research has been devoted to the effect of hearing aid use on speech, essentially no research is available relating to hearing aid use and perception and enjoyment of music. The purpose of this study was to examine the listening behavior and attitudes of hearing aid users regarding music.

A questionnaire was developed and submitted to a population of hearing aid users ranging in age from 8 to 91 with a mean age of 62.3. Subjects were asked to respond to the questionnaire items by using equal-interval scales ranging from 1 to 7. The numbers were associated with appropriate modifiers such as moderately, greatly, etc. A rating of 1 was the most negative response and 7 was the most positive response. Responses were obtained from 178 subjects consisting of 95 men, 81 women, and 2 children.

In response to the inquiry regarding the importance of music before hearing impairment and aid use, 88% indicated that listening to music was at least moderately important to them. Twenty-nine percent indicated that listening to music was of great importance to them.

A comparison of the scaled responses for before hearing loss and after hearing loss and aid use revealed a statistically significant difference between the mean responses, supporting a significant reduction in music listening with hearing aid use. Similar differences were found for items examining the enjoyment of music. A statistically significant reduction in the enjoyment of music with aid use was found compared to enjoyment prior to loss of hearing. Furthermore, 58% of the subjects reported that the loss of enjoyment as of at least moderate importance; 15% indicated that the loss was of great importance.

The respondents were asked to indicate the degree to which hearing aids assisted the enjoyment of music in comparison to not wearing an aid. Sixty percent of the subjects reported receiving at least moderate help, and 35% indicated that the aid helped greatly.

Additional information derived from the survey indicated that those respondents who wore binaural amplification reported receiving a greater degree of assistance from amplification in their enjoyment of music compared to those who wore one aid. Also, those who had used aids longer indicated obtaining more help from their aids in listening to music. Finally, those respondents who indicated receiving the most help in listening to music also indicated a greater degree of overall satisfaction with their hearing aids.

THE ACOUSTICS OF IN-THE-EAR HEARING AIDS

John R. Franks,
Northern Illinois University

The audiologist who recommends an ITE hearing aid for his or her client typically places the responsibility for selection of the amplification parameters upon the manufacturer. In most cases, unless an ITE oriented master hearing aid is used, the audiologist will provide the ITE manufacturer with an audiogram that indicates the lower limits of sensitivity and the upper boundaries of tolerance for the client. The manufacturer then evaluates the so-supplied information and selects the electronic components and casing style to be supplied with

the hearing aid. The success of the fitting of the instrument is usually dependent upon the client's acceptance or rejection of it.

Some recent work with KEMAR has provided a data set which should make the task of determination of amplification parameters easier for the ITE hearing aid manufacturer. This work has been oriented toward 1) establishing the differences in sound pressure levels created by earphones and canal-placed hearing aid receivers, 2) establishing the output characteristics of ITE hearing aids, 3) establishing the effects of venting ITE hearing aid cases on receiver frequency response, and 4) establishing the effects of these vents on the signals incident upon the hearing aid case.

The sound-field work has been conducted in a diffuse, rather than an anechoic sound field. The diffuse sound field provides a field-to-head acoustic transfer function which is equivalent to the average of all such functions for many angles of signal incidence in the anechoic sound field. Thus the response of a hearing aid measured in the diffuse sound field is independent of the effect of angle of signal incidence.

The data which will be presented will show the difference between the effects of venting ITE hearing aid cases and traditional earmolds, both on the signals provided by the receiver and incident upon the hearing aid case. The differences between frequency responses as measured in 2-cc couplers and the ear of KEMAR will also be shown for different types of hearing aid receivers used in ITE hearing aids.

COMMUNICATIVE DISABILITY ASSESSMENT USING AN ARTICULATION INDEX PROCEDURE

Chaslov Pavlovich,

University of Mississippi, Jackson

The Articulation Index Theory (French and Steinberg, 1947) postulates that speech intelligibility is uniquely related to a quantity called "articulation index", which for any specified, normal hearing, speaker-listener pair, can be computed from the intensities of speech and competing noise reaching the ear of the listener. To test the applicability of the theory to communicative disability assessment when hearing loss is modeled as internal noise, the PB-word discrimination scores for different filtering and noise conditions (Table 1) were obtained for normal hearing, lesser hearing impaired and greater hearing impaired subjects. Mean thresholds for each group are shown in Figure 1. Figures 2, 3 and 4 depict the predicted (solid lines) and the mean observed discrimination scores for all three groups. Clearly, AI was a good predictor for normal and lesser hearing impaired group, but subjects from the greater hearing impaired group exhibited a disproportionate loss in speech discrimination, over and above that predicted on the basis of their hearing sensitivity.

As the reduction in the AI did not prove to be a good descriptor of the effective reduction in the auditory area needed for speech perception, an attempt was made to calculate this reduction R from the obtained speech discrimination scores. Further, R was correlated with two different measures of social handicap (Noble and Atherley hearing measure scale, 1970; and the subject's direct magnitude estimate of the handicap). Results, which are given in Table 2, when analysed reveal that: (1) Whichever functional relationship (linear, logarithmic or power) was supposed to exist between R and subjective measures, a statistically significant correlation was obtained ($p < 0.05$); (2) The difference between correlation coefficients for different functional relationships was not significant. This indicates that auditory handicap is a composite sensory continuum with both prothetic and metathetic components; (3) The magnitude of the correlation is not high but it is concluded that the method is worth further investigation.

A COMPARATIVE PERFORMANCE STUDY OF THE LIBBY HORN VERSUS STANDARD #13 TUBING

Florence Davenport
Margaret A. Wylde

Recent studies of coupler (earmold) modifications in hearing aids have shown that a one piece tubing with a tapered internal diameter, called the Libby horn, can smooth and extend the high frequency response of a hearing aid compared to the frequency response of the same hearing aid coupled to standard #13 tubing.

Although investigators have reported the superiority of the Libby horn based on etymotic gain measures and clinical observations (Libby, 1981; Mueller, et. al., 1981) there has been little experimental data reported supporting the subjective preference of the Libby horn over standard #13 tubing (Mueller, et. al., 1982).

The purpose of this study was to determine whether normal hearing subjects and three groups of sensorineural hearing-impaired subjects could discern qualitative differences between the acoustic output of their hearing aids delivered to their ears through the Libby horn inserted in a Killion 8cR earmold compared to #13 standards tubing inserted in the same earmold.

Forty subjects, 10 normal hearing, 10 with flat sensorineural hearing loss, 10 with a sloping (12 dB/octave) sensorineural hearing loss, and 10 with normal hearing through 1000 Hz and a severe high frequency hearing loss participated in the study. The quality of sound produced by the hearing aid coupled with the Libby horn and with the #13 tubing was rated by each subject on 9 adjective scales (Gabrielsson et al., 1980) while listening to 4 taped programs. The 72 experimental conditions (2 couplers \times 4 programs \times 9 scales) were counter-balanced across subjects. The programs, presented at 65 dB SPL through a loudspeaker in a sound-treated room were music, continuous discourse, continuous discourse with a competition of multi-talker speech babble at a -10 dB signal-to-noise ratio, and a conver-

sation between two speakers.

A stock earlevel hearing aid was used with the normal hearing subjects. The hearing-impaired subjects used their own hearing aid.

Functional gain was measured (Pascoe, 1975) for each subject both with the Libby horn and with the #13 tubing.

The functional gain measures demonstrated a slight, but significant (.05) improvement in aided thresholds with the Libby horn. The results of the qualitative judgements were equivocal, some measures suggested the superiority of the Libby horn while others suggested better quality from the #13 tubing.

HEARING AID FITTINGS IN UNILATERAL LOSS WITH POOR SPEECH DISCRIMINATION

John R. Coleman, Otologic Medical Group, Inc.

A widely held assumption among persons involved in the fitting of hearing aids is that ears with unilateral reduced discrimination (i.e. lower than 70 or 80% for Pb's) cannot benefit from use of a hearing aid. The accompanying rationale is that amplification of distorted speech (as measured by Pb's) will only further confuse the patient. This assumption has not been consistent with our clinical experience. We have found that the successful fitting of patients with this type of hearing problem does require some special attention to certain characteristics of the loss during the evaluation in order to achieve satisfactory hearing aid use, but should not be ruled out as "unaidable".

Eight satisfied monaural hearing aid users were evaluated. These subjects have unilateral hearing loss, with reduced speech discrimination in the aided ear. Average age of this group was 55 years, with etiologies including Meniere's, hereditary, toxic, sudden vascular, and cause unknown. The better ear in this group had an average SRT of 15 with 92% speech discrimination, the group's poorer ear had an average SRT of 75 dB with 43% maximum speech discrimination score. The average length of binaural aid use was approximately three years, with a range of 3 months to 6 years. Two subjects had initially worn a CROS arrangement routed to the better ear, before trying the hearing aid on the poor discrimination ear that they now prefer.

A fundamental issue in dealing with the reduced discrimination problem is whether single-word Pb scores are valid as an indicator of the usefulness of amplification in an impaired ear. Despite the fact that this group had 43% Pb discrimination, their discrimination of spondaic words at the same presentation level was typically over 80%, and their description of running speech was described as "understandable". In addition to evaluation with more redundant speech materials, evaluation indicated that these patients tended to have a more narrow dynamic range, with loudness tolerance problems. In some cases, prominent frequency distortion when listening to speech was observed by the patient, characterized as either "low-pitched" or "high pitched".

Elimination of objectionable factors in amplified speech by use of compression output limiting and variable frequency response were important to comfortable hearing aid usage.

An extensive review of literature has revealed no substantive data or research indicating that unilateral reduced speech discrimination (via Pb scores) will have deleterious effects on speech understanding in the binaural mode. Theoretical work on decreased frequency resolution as a source of reduced speech discrimination exists, however this has been shown to modify but not eliminate identification of multi-formant speech information. No research has indicated that the dichotic (modified and normal) presentation of speech produces reduced speech understanding.

Many patients with unilateral loss and good hearing in the remaining ear can function adequately with no major difficulty. However, the problems associated with monaural hearing are well known, and some persons in more demanding communication situations consider their problem significant. For the patient interested in maximizing speech understanding in professional and social situations, binaural hearing is clearly advantageous. The binaural effect, including aspects

of binaural fusion, summation, squelch effect, elimination of head shadow, localization, and an improvement of a subjective sense of "balance" are all advantages that the patient with both unilateral hearing loss and reduced speech discrimination can still obtain benefit from. This is consistent with the reports from the subjects evaluated in this group.

It is not the intention of this report to generalize that all patients with monaural hearing loss and reduced speech discrimination should wear an aid on the affected ear. The purpose of this study is to refute the generalization that these patients cannot wear an aid. Clinical experience has indicated that some patients can satisfactorily use an aid in preference to a CROS system. The characteristics of this group are presented. Complete audiometric data, descriptive data (including occupation), additional evaluation and speech testing results, functional hearing aid gain and frequency response data will be presented. A summary of each patient's report on the advantages/disadvantages of their hearing aid use will be reviewed. Supported by funds from the House Ear Institute, Los Angeles.

APPLICATION OF SILMAN AND GELFAND 90TH PERCENTILE LEVELS FOR ACOUSTIC REFLEX THRESHOLDS

Wayne O. Olsen, Christopher D. Bauch, Stephen G. Harner
Mayo Clinic, Rochester, Minnesota

Silman and Gelfand (1981) reported acoustic reflex threshold data for a large sample of patients having hearing losses attributable to cochlear pathology. Included in their publication were 90th percentile levels to establish upper limits for reflex thresholds as a function of hearing loss at 500, 1000 and 2000 Hz. The purpose of our study is to report data for this type for a smaller group of patients with surgically-confirmed retrocochlear pathology.

Subjects were 30 patients having surgically-confirmed cerebellopontine angle tumors (26 neurilemmomas, 4 meningiomas). In addition, reflex results were reviewed for 30 patients with similar hearing losses not attributable to cerebellopontine angle tumors.

Acoustic reflex thresholds were obtained with an Amplaid Model 702 immittance unit. Responses were monitored on a strip chart recorder.

Results were interpreted as abnormal for 25 (83%) of the tumor patients and for 1 (3%) of the non-tumor patients. The non-tumor patient with abnormal reflexes had an elevated reflex threshold at 2000 Hz.

These results suggest that the upper limits for reflex thresholds as a function of hearing loss recommended by Silman and Gelfand are appropriate, at least as applied to these two samples of patients. Reflex decay was also measured for these patients. Implications of the reflex threshold and reflex decay results will be discussed.

COMPARISON BETWEEN AER AND BEHAVIORAL THRESHOLDS IN NORMALLY AND ABNORMALLY HEARING CHINCHILLAS

Robert I. Davis, John A. Ferraro.

At present, there is a lack of agreement in the literature regarding the use of a specific electrophysiological response that corresponds in order of magnitude and stability to behaviorally determined responses from experimental animals. Evidence from Henderson, et. al. (*J. Acoust. Soc. Am.* 46: 474-475, 1973) has shown that the auditory evoked response (AER) recorded from the inferior colliculus (IC) may be a valid indicator of hearing sensitivity in normally hearing chinchillas. For practical application as a research tool, however, correspondence between responses must also be demonstrated in abnormally hearing populations. The present study was designed to compare AER and behavioral thresholds from the chinchilla before and after acoustic overstimulation. A demonstration of correspondence between thresholds would provide support for the application of the AER technique as an alternative to the inherently subjective and time consuming procedures associated with behavioral conditioning.

Bipolar electrodes were chronically implanted in the IC of seven behaviorally conditioned chinchillas. AER and behavioral thresholds to 20 msec. tone bursts were determined for a range of frequencies before and after a 4 hour exposure to a 2000 Hz, 120 dB SPL pure tone for six of the animals. One subject served as a control and received no exposure.

Our results revealed a close correspondence between AER and behavioral thresholds in both the normal and abnormal

(cont. on p. 12)

Abstracts (cont. from p. 11)

ear of the same animal. In almost all subjects, the greatest difference between mean thresholds at any one frequency did not exceed 15dB. Post exposure thresholds displayed mild to moderate losses in sensitivity in the 1 kHz to 4 kHz range.

Our findings justify further development of this particular AER as an indicator of hearing sensitivity in the chinchilla. In particular, the application of the technique should be examined in populations with cochlear pathology in regions other than those observed in this study.
(Supported in part by a grant from the Ohio State University Graduate School).

VALIDITY OF NEWBORN HEARING SCREENING PROGRAMS: AN AUDITORY BRAINSTEM RESPONSE EVALUATION

John T. Jacobson, Ph.D.
School of Human Communication Disorders
Dalhousie University

Introduction:

Recognizing the need for the early identification of hearing impairment, the Joint Committee on Infant Hearing (1970, 1972) recommended the use of a high risk register (HRR) and behavioral audiological follow-up for infants at risk. Although testing procedures and screening techniques have been modified and improved, only recently have means been available to accurately evaluate the validity of behavioral newborn screening. With recent advancements in electrophysiological measurement, recommendations have urged the implementation of auditory brainstem response (ABR) audiometry as a supplement to newborn screening. The purpose of this paper is to report the results of a newborn hearing screening program incorporating a high risk questionnaire, behavioral screening and ABR audiometry.

Methods and Procedures

Over a three year period, 13,374 were born at the Grace Maternity Hospital in Halifax. Newborns were classified into three categories: (1) at risk for hearing loss, (2) those admitted to the intensive care nursery (ICN), and (3) a normal control group. Based on the results of the HRR and a behavioral test protocol, ABR audiometry was completed on 350 newborns. Acoustic clicks were presented monaurally to each ear at intensities of 60 dB and 30 dB nHL. An ABR screening failure was considered the absence or prolonged latency of a Wave V response.

Results/Discussion

Discussion will include the incidence and pass-fail results of the 3 stage screening program. Of the 350 infants tested, 6 percent of those classified as "high risk" for hearing loss were found to have either unilateral or bilateral sensorineural hearing impairment. Emphasis will be placed on the large percentage of behavioral false-positives and the validity of newborn behavioral screening as demonstrated by ABR audiometry. Infant failures will be compared to normative absolute (Wave I, III and V) and relative (I-III, III-V and I-V) latencies and relative amplitude ratios (V/I) as a function of maturation and intensity (see attached tables). Finally, the incidence of hearing impairment by category and clinical considerations will be discussed.

"PROGRESSIVE" HEARING LOSS IN SCHOOL-AGED CHILDREN

Roslyn M. Bendet, Audiologist
Pittsburgh Public Schools

Educators of hearing impaired children generally assume that the congenital sensori-neural hearing losses exhibited by these children remain stable over time. Progressive sensori-neural hearing loss usually is associated by teachers with otologic disease processes. Over the past few years, the incidence of progressive hearing loss and subsequent changes in auditory function has been of concern to the educational and clinical audiologists as well as the teachers working with children in the Pittsburgh Public Schools. Teachers and audiologists working to habilitate hearing impaired children

need to be aware of any changes in hearing function in order to plan and carry out appropriate educational programming for these children.

This study will explore a number of parameters associated with progressive hearing loss in a population of hearing impaired children in a public school program. The population includes approximately 150 school-aged children in kindergarten through twelfth grade. The children are enrolled in self-contained classrooms, resource rooms, or in the itinerant program in the Pittsburgh Public Schools' Programs for the Hearing Impaired.

The following questions will be addressed in the presentation:

Incidence: Are the numbers of school-aged children exhibiting decreases in hearing significant?

Audiometric Testing: What differences in audiometric pattern and degree of hearing loss have been noted?

Hearing-for-speech Testing: What changes in speech recognition and discrimination have occurred?

Amplification: Has over-amplification contributed to progressive hearing loss? The Pittsburgh Public Schools programs to monitor user gain with classroom amplification as well as personal hearing aids will be discussed.

Medical-otologic: Have medical-otologic causes been identified for the observed decreased hearing?

Behavior Changes: What behavioral parameters have been associated with decreased hearing?

Educational Needs: How does a public school program alter or individualize rehabilitative programming for students exhibiting progressive hearing loss?

AUDITORY BRAINSTEM RESPONSE WITH DEMYELINATING DISORDERS

Hiroshi Shimizu and James M. McDonald
Department of Otolaryngology
The John Hopkins University School of Medicine
Baltimore, Maryland

Demyelinating disorders, such as multiple sclerosis (MS), are not unrelated disease entity in ENT practice because of its interesting affinity for the vestibular system. MS is one of the interesting diseases for the differential diagnosis of Meniere's disease and the symptoms sometimes resemble a CPA tumor. Therefore, auditory brain stem response (ABSR) testing can be an additional useful procedure for the differential diagnosis.

This paper is to report our experience with 64 cases of MS, 4 cases with metachromatic leukodystrophy (MLD) and 5 cases with adrenoleukodystrophy (ALD).

All patients underwent audiometric evaluation before the ABSR testing. Clicks were presented at a 20/sec repetition rate except for 11 MS cases which were subjected to a study on the effect of the click rate. The data on the presence or absence of wave I, III and V, the absolute latency, the interwave interval and interlatency difference in detail will be presented. Sixteen cases with MS (25.8%) showed the absence of all response components. The absence of wave V was found in 22 MS cases (35.5%).

ABSRs were abnormal in two of the late infantile-onset and one juvenile-onset MLD, including a 14-month-old child with normal neurological examination and normal peripheral nerve conduction. ABSR helped identify early pathology. A new high performance liquid chromatographic assay was used to quantitate the urinary sulfatide excretion at the picomole level.

All five cases with ALD showed either absence of the response or the prolonged absolute and interwave latencies. One of them gave clear normal slow vertex response (SVR), while no discernible ABSR was obtained. Two of them had little speech discrimination ability although no hearing sensitivity loss existed.

The issue on determining upper normal limit will be addressed by utilizing 2 SD and 3 SD for the criterion of the upper normal limit for the wave latency.

SUMMARY

Forty out of 63 MS patients had a provisional diagnosis of MS. The incidence of abnormal ABSR in the provisional MS group was 65.0% while 78.3% of the patients with definite MS showed abnormal ABSR. However, the incidence of abnormal ABSR in patients who subsequently developed definite MS was 71.4%.

We studied two siblings with late infantile onset of MLD and one with juvenile onset of MLD. ABSR's were abnormal in all patients. One patient was a 14-month-old infant who was asymptomatic, with normal neurologic examination and peripheral nerve conduction, but fibroblast arylsulfatase, an enzyme assay, was diagnostic of MLD. ABSR was apparently sensitive enough to detect brain stem involvement in this case.

The ALD group consisted of six patients with ALD and two ADL carrier. All patients, including two ALD carriers, except

one ALD patient showed abnormal ABSR. Like MS, the first and second order neurons are more often involved than the third and beyond.

The latency increased with faster repetition rate of click but no significant difference in the latency change between normal Ss and the study group as far as up to 60/sec. is concerned. There was no high correlation between abnormal ABSR and abnormal acoustic reflex in MS, MLD, and ALD.

In conclusion, the abnormal ABSR was positive in a substantial proportion of MS, MLD and ALD and the test helped identify a silent lesion in the brain stem. The abnormality was not specific to any of the disorders.

Standards (cont. from p.6)

electrode may be placed anywhere on the subject. The manner of application should follow customary laboratory procedures of an electroencephalographic facility, but special precautions must be followed for preterm or new born infants. (See section III.)

Amplifiers and filters: The amplifiers should meet customary standards of safety for application to patients. Their overall gain should be sufficient to utilize fully the computer's digitizing capability to achieve adequate resolution of signals as small as 50 nanovolts. The pass-band of the filters for the ABR should be approximately 30 to 3000 Hz (3dB-down points) and they should have slopes of at least 6 dB/octave.

Averaging Computer: The maximal dwell time should be 50 msec (20kHz sampling rate) when using a sweep time of 10 to 20 msec. Artifact rejection of traces above a certain amplitude should be provided.

Plotting convention: There should be notation of the electrode used as G1 input to the amplifier, i.e. the "active" electrode, and of the direction of display of the polarity of this electrode in the ABR. There was no consensus as to a single convention for the polarity of such a display.

Protocol for Neurological Assessment: Stimulus intensity should be approximately 90dB peak equivalent SPL. One slow rate of 25/sec or less and a faster rate of 50/sec or more should be used. All averages should be replicated until the latencies of principal peaks are within 0.2 msec of each other.

III) The ABR as screening test for audiological evaluation:

The same minimal requirements as for neurological evaluation are recommended with following additions and exceptions:

1. Sedation of infants may be necessary.
2. Capability to present bone-conducted signals should be available.
3. Collodion should not be used to affix electrodes to pre-mature or full-term newborn infants because of their fragile skin as compared to the skin of adults.
4. Earphone bands and standard earphone cushions customarily used in adults can cause collapse of the ear canal in neonates. Holding the earphone gently against the ear can void this problem.
5. Each ear should be tested separately, using contralateral noise masking if the thresholds differ significantly. Several intensity levels should be tested to cover both suprathreshold and threshold levels.

IV) The ABR as a frequency-specific audiological test:

There are two general approaches to frequency selectivity, one by shaping the stimulus (tone bursts or filtered clicks), the other by masking undesired frequencies (notched noise, derived responses). There was no consensus on the method of choice but full agreement on the need for further experimental and clinical evidence to evaluate the compromises that are inherent in each method. There is the possibility that other evoked potential components may be more suitable for audiological testing.

Officers Elected at First Meeting of AAO-HNS Board of Governors

The American Academy of Otolaryngology-Head and Neck Surgery's newly created Board of Governors held its first meeting October 17 in New Orleans. The function of this group is to provide communication between the Academy's Board of Directors and the membership through the approximately 120 local, state, regional, national and international otolaryngological societies. Each society has one delegate plus an alternate who serves a three year term which is renewable one time. It is anticipated that the Board of Governors will meet twice a year in conjunction with the national spring and fall meetings.

Dr. Marvin A. Singleton was elected Chairman of the Board of Governors. He is in the private practice of general otolaryngology and related allergies in Joplin, Missouri. Dr. Singleton is a Counselor for the Missouri State Medical Association and past President of the Missouri ENT Society. He will be an invited guest at the AAO-HNS Board of Directors meetings.

According to Dr. Singleton, "the Board of Governors will be the conduit for information from the grass routes of organized otolaryngology to the Board of Directors of the Academy. This process will make the Academy leadership more responsive

to the socioeconomic and political problems of the general membership. The Board of Governors will also request residents training in otolaryngology and the general good of the patients of our members. It can help the Academy become a more dynamic and democratic medical organization if the societies present their issues well in advance of the meetings."

Willard Fee, Jr., M.D. was elected Chairman-Elect. Dr. Fee is Chairman of the Division of Otolaryngology-Head and Neck Surgery at Stanford University School of Medicine in Palo Alto, California.

Robert J. Keim, M.D. of Oklahoma City was elected Secretary. Dr. Keim is in private practice and is the current Secretary at the American Neurotology Society.

The predecessor Academy merged with the American Council of Otolaryngology — Head and Neck Surgery on January 1 of this year. The new Academy, whose officers are in Washington, D.C., has more than 7,000 members. According to Executive Vice President Harry W. McCurdy, M.D., "the Board of Governors has the potential to be the most important addition to result from the merger."

ANNOUNCEMENT Practical Short Course in ABR offered

The Kresge Hearing Research Laboratory of the South, LSU Medical Center, will present A Practical Short Course in Auditory Brainstem Response, February 4-8, 1983, and again June 10-14, 1982, each with the last day as an optional additional practice day. The courses are co-sponsored by the Lions Eye Foundation of Louisiana, the Eye and Ear Institute of Louisiana and LSU Office of Continuing Medical Education. Featured will be morning lectures on Anatomy, Physiology, and Instrumentation as they relate to applied auditory physiology, and afternoon labs with hands-on, practical instruction in ABR. Special concurrent sessions will be available for people with no experience in electrophysiological measurement. Participants will have the opportunity to talk with representatives of major equipment manufacturers and to try their products.

The \$400 tuition includes, in addition to an educational opportunity of the finest quality: reduced room rates in the hotel in which the course will be held, a free evening jazz party featuring outstanding New Orleans musicians and hors d'oeuvres, and free coffee and refreshments throughout the course. Free transportation to and from the airport, courtesy of the Eye and Ear Institute, may be available.

The Lions Eye Foundation of Louisiana may once again provide some fall tuition scholarships for graduate students, residents, audiologists, etc. Enrollment in the course is limited to 40 paid participants, or 5 workers per available computer. For further information, application forms, and information on applying for scholarships, please contact Course Coordinator, Kresge Hearing Research Laboratory, 1100 Florida Avenue, Building 124, New Orleans, Louisiana, 70119, or call (504) 947-6641.

I/INCE Requests Research Items

The International Institute of Noise Control Engineering (I/INCE) was founded in 1974 as an organization dedicated to the application of noise control technology for the benefit of the public. It provides leadership through the organization of international conferences and seminars on noise control engineering, especially the INTER-NOISE series of conferences. I/INCE also seeks to develop interdisciplinary contacts between Noise Control Engineering and other related fields of work, and promotes international cooperation in research on noise control. I/INCE has twenty member societies in seventeen countries spread over five continents.

As part of its responsibility to promote cooperation in

research, I/INCE publishes a newsletter which contains news items of international interest. One of the objectives of the newsletter is to publish a survey of research in noise control in progress in laboratories throughout the world. These items will appear in a "Research" column of the newsletter. Individuals working in noise control research are encouraged to send such news items to the newsletter. It is not necessary to provide details of the results of the research; the scope and subject matter are sufficient. Information should be sent to Dr. A. Cops, Editor, I/INCE Newsletter, Celestijnenlaan 200D, B-3030 Heverlee, Belgium. Information on other I/INCE activities may be obtained from the I/INCE General Secretariat at the same address.

TEDER ELECTED CHAIRMAN OF HIA STANDARDS AND TECHNICAL COMMITTEE

On September 13, during a meeting in Washington, D.C., members of the HIA Standards and Technical Committee elected Harry Teder their chairman. The committee had convened for the purpose of this election and to review results of efforts thus far on the hearing aid/telephone compatibility standard. Mr. Teder recently testified regarding that standard before the Sentates Communication Subcommittee

on behalf of the HIA.

Mr. Teder is the Chief Engineer, Hearing Instruments, at Telex Communications, Inc., Minneapolis, M.N. He is a graduate of Dartmouth College and has been with Telex since 1963. Mr. Teder has been a member of the HIA Standards and Technical Committee he now chairs since 1969, and is also a member of ANSI working groups S3-48 (Hearing Aids) and S3-69 (Auditory Trainers). He is a member of the Audio Engineering Society and the Upper Midwest Chapter of the Acoustical Society of America.

ADVANCED ABR WORKSHOP March 25-27, 1983

The Kresge Hearing Research Laboratory of the South, part of LSU Medical Center's Department of Otorhinolaryngology, New Orleans, Louisiana, is offering an Advanced ABR Workshop especially tailored to people experienced in auditory brainstem applications. The course will be held March 26-27, 1983. The course will feature case reviews and participants will be encouraged to bring their difficult cases. Special attention will be given to ipsilateral vs. contralateral recording techniques, normal variability, binaural interaction studies, simultaneous masking studies, visual and somato-sensory potentials, and an opportunity for equipment updates. Attention will be given to storage, recall, and data handling techniques for certain kinds of computer configurations.

Tuition will be \$300 for new attendees, \$250 for previous attendees of a Kresge course. The tuition includes, in addition to the educational opportunity, reduced hotel rates, free evening jazz party featuring outstanding New Orleans musicians and hors d'oeuvres, free coffee and refreshments throughout the course.

Free transportation to and from the airport and between the hotel and course location may be available courtesy of the Eye and Ear Institute. The course is co-sponsored by the Lions Eye Foundation, the Eye and Ear Institute of Louisiana and LSU Office of Continuing Medical Education. For further details write to: Advanced ABR Workshop Coordinator, Kresge Hearing Research Laboratory of the South, 1100 Florida Ave., New Orleans, LA 70119.

Ear and Hearing Goes to Soviets

Editor's Note: Ross Roeser, Editor-In-Chief of Ear and Hearing, received this letter from The State Central Scientific Medical Library, MOSCOW, USSR.

Dear Dr. Roeser,

We should be most obliged if you could send us on a regular exchange basis your periodical "Ear and Hearing", which is of great interest to our specialists in this field of medicine.

We could offer you in exchange our medical journals (up to two titles) from the list attached to this letter.

Please note that almost all of them are supplied with English summaries of the original papers.

Looking forward to your early reply.

Sincerely yours,

N.A. Yakunin
Director
Cand. med. Sci.

It is a comforting thought to think that, in the midst of all the nuclear arms controversy, our profession maintains an exchange of knowledge.

Harry Teder

Beltone Begins Search

Beltone Electronics Corporation President Lawrence M. Posen today announced that the search has begun for the 1983 winner of the Beltone Distinguished Teaching Award in Audiology.

This award is given annually by Beltone to an outstanding audiology instructor in the United States or Canada, nominated by an audiology student or graduate. The intent of the award, according to Posen, is to honor the teaching profession for the vital role it plays in shaping the future of the field of audiology. The top three instructors will each receive a cash prize, their universities will be given grants and the students nominating them will be awarded a cash prize from Beltone.

Judging in the competition will be based on the recommendation of the student making the nomination, the instructor's department chairman or dean's recommendation, the candidate's essay on "The Future of the Profession of Audiology," curriculum vitae and the overall impression of the judges.

Judges for the competition will be: Robert Goldstein, Ph.D., University of Wisconsin; Mary Kawell, student representative, University of Illinois; David Lilly, Ph.D., University of Michigan; David Lipscomb, Ph.D., University of Tennessee; Judith Rassi, M.A., Northwestern University; Ross Roeser, Ph.D., University of Texas, Callier; Zahrl Schoeny, University of Virginia (1982 winner); Arnold Small, Ph.D., University of Iowa; Laszlo Stein, Ph.D., Michael Reese Medical Center; Bruce Weber, Ph.D., Duke University Medical Center; and Don Worthington, Ph.D., Boystown Institute for Communication Disorders.

The winner of the 1983 award will be announced at the convention of the American Speech-Language-Hearing Association (ASHA) in Cincinnati later this year.

Naunton Provides Recommendations To Anderson on Committee

At the 1982 Executive Committee meeting President Ralph Naunton was made chairman of a committee on committees. His task was to recommend standing committees and chairmen to President Anderson. Dr. Naunton, immediate past president of AAS, recently provided his recommendations to President Anderson. In his recommendations Dr. Naunton suggested the formation of seven standing committees of the Society. The various committees that were suggested will be published in the Summer/Fall issue of Corti's Organ. Any member wishing to make recommendations regarding the formation of committees, or wishing to serve on a committee, should contact President Anderson at his new address: 11003 West 27th Avenue, Lakewood, Co. 80215.

Annual Meeting Announced Keith Calls For Papers

The 10th Annual Meeting of the American Auditory Society will be held in Cincinnati, Ohio on November 17, 1983. In recognition of our progress in developing intra-professional relationships, in conducting an informative annual meeting, and in the development of a quality professional journal, the theme of the meeting will be "A Decade of Progress."

The Program Committee is presently soliciting papers of scientific and clinical interest to be considered for presentation at the meeting. Interested persons are invited to submit five copies of a 300-word abstract with a brief summary by June 1, 1983 to the following address:

Robert W. Keith, Ph.D.
Department of Otolaryngology
Mail Location #528
University of Cincinnati Medical Center
Cincinnati, Ohio 45267

The Committee will send acceptance notices on August 15, 1983.

J.D. Harris to Address 1983 AAS Convention

It has been announced that Dr. J.D. Harris will be this year's Keynote Speaker at the 1983 AAS convention in Cincinnati. (Further information will appear in the pre-convention issue of Corti's Organ.).

History of The AAO-HNS, Inc.

The Western Ophthalmological, Otolological, Laryngological and Rhinological Association was founded in 1896 in Kansas City, Missouri. This first meeting of about 50 eye, ear, nose and throat specialists eventually blossomed into the American Academy of Ophthalmology and Otolaryngology. The purpose of the organization was to encourage the study and practice of medicine and surgery in their relation to the eye, ear, nose, and throat.

As medical and surgical techniques advanced, this one specialty divided into two distinct entities: ophthalmology and otolaryngology. Separate certifying boards were established. In 1916 the American Board of Ophthalmology and in 1924 the American Board of Otolaryngology were created. The AAO continued to serve both specialties until 1979, when the Academy divided into two separate associations. The ophthalmology headquarters moved to San Francisco while the otolaryngology headquarters remained in Rochester, Minnesota.

On January 1, 1982 a unification occurred with the merger of the American Academy of Otolaryngology-Head and Neck Surgery and the American Council of Otolaryngology-Head and Neck Surgery. The Council had been created in 1968 to serve the specialty's governmental and socioeconomic needs. The new entity assumed the former's name and is now headquartered in Washington, D.C. It was felt that joining the two organizations would strengthen and enhance the effectiveness of each. The new organization assumed the responsibilities of both the predecessor associations.

The function of the American Academy of Otolaryngology-Head and Neck Surgery today is to serve as the governmental and socioeconomic support base for all otolaryngologists, advance the science and art of medicine related to otolaryngology and provide educational services for the specialty.

The Board of Directors determines policy for the Academy. The President is the chief executive officer and sees that all orders and resolutions of the Board of Directors are carried out. His term of office is one calendar year. Other officers of the Academy include the President-Elect, Vice-President, and Secretary-Treasurer. The Executive Vice-President is an otolaryngologist hired by the Board to serve as chief administrator of the Academy. He hires and supervises the staff to carry out the administrative work of the corporation.

Special services include a job information exchange, residency training and fellowship vacancy lists, a comprehensive calendar of courses, meetings and workshops in the U.S. and abroad, and up to date mailing lists of the specialty.

The Academy has a legislative alert system which provides volunteers and representatives of all otolaryngology societies with key information about proposed legislation and regulations affecting the specialty. In this way otolaryngologists can quickly respond as a unified group to both federal and state proposals.

Amplifon Names Keidel As CRS Award Winner

The Amplifon Board of Directors met on February 10th in order to vote for the winner of the 1982 Amplifon Research and Studies Center International Prize and to scrutinize the votes which had arrived from the other voting societies.

The winner, resulting from the poll, is Prof. W.D. Keidel, from the Institute of Physiology and Biocybernetics, University of Erlangen — Nurnberg, Germany.

The Prize awarding ceremony will be held on April 27th, 1983 and its final program will be sent to you as soon as ready. Further details will appear in the next issue of Corti's Organ.

Lorne Greene Leads Better Hearing and Speech Campaign

The 1983 Better Hearing and Speech campaign will be launched April 29 in Washington, D.C. Actor Lorne Greene will release a special message from President Reagan, introduce poster child Brooke Broberg, and begin a series of national media appearances.

Mr. Greene is well-known for his leading roles in the TV series Bonanza, Battlestar Galactica and Code Red. In 1982, he filmed a public service announcement for the Academy and the Better Hearing Institute. Mr. Greene explained how he overcame his own hearing loss with hearing aids and encouraged others with hearing problems to get help medically, surgically, with hearing aids or through rehabilitation.

This year's poster child, four-year-old Brooke Broberg of Shawnee, Kansas, was selected from more than 200 nationwide nominees. She receives speech and language therapy at the Communicative Disorders Department of the Research Medical Center in Kansas City, MO. Her articulation disorder is characterized by omissions, substitutions, and distortions of many sounds.

"Sharing Life Through Hearing & Speech" is the theme of this year's campaign. The slogan will be used in the Better Hearing & Speech poster, TV and magazine public service announcements and other publicity.

The Better Hearing & Speech public information campaign

is jointly sponsored by a consortium of the major non-profit organizations concerned with communicative disorders.

Captioned Television, U.S.A.

In March 1980, the U.S. National Captioning Institute (NCI) was created to assist the television networks in making their programming accessible to the estimated 16 million Americans with significant hearing loss. Three of the four major networks (ABC, NBC and PBS) began cooperating in the captioning selected programs now totalling near 40 shows a week.

The system used is closed captioning which means text can only be seen with the use of a special decoder around \$290. Approximately 50,000 sets of the special equipment have been purchased.

Details are available from NCI, Suite 1500, 5203 I Pike, Falls Church, Virginia 22041, USA.

What is the Institute of Noise Control Engineering of the U.S.A.

The Institute of Noise Control Engineering of the United States of America (INCE/USA) is a nonprofit professional organization that was founded in 1971.

The purpose of INCE/USA is to assist in the development and application of noise control technology. The objectives of the Institute include developing professional qualifications for noise control engineers, establishing an effective and continuing mechanism for exchanging information on the technology of noise control engineering, and stimulating development of engineering education in noise control.

The notation "Member INCE" after an individual's name may be used to designate that an individual is a member of the Institute and has met specific professional qualifications in terms of both experience and an examination in noise control engineering. Individuals interested in noise control may also join the Institute as Affiliates or Associates. Organizations contribute to the activities of the Institute through a Liaison Program.

The Institute is governed by a Board of Directors elected by the members. The officers are appointed by the Board and the principal officer is the President of the Institute. All officers serve without financial compensation; there is a no paid staff.

The Institute participates in coordinated efforts with international and national societies and organizations. It is a member organization of the multimember International Association of Noise Control Engineering, INCE/USA supports worldwide efforts for the control of noise. In the USA, the Institute works closely with other professional societies, organizations and agencies toward the same goal.

The Institute organizes national and international conferences on noise control engineering. The INTER-NOISE and NOISE-CON international conferences and the NOISE-CON national conferences held in the USA are organized by INCE/USA. Three-day training seminars are usual in conjunction with these conferences.

The Institute publishes proceedings of the noise control conferences held in the USA (INTER-NOISE and NOISE-CON) as well as the refereed technical journal "Noise Control Engineering" and the bimonthly "NOISE/NEWS" newsletters.

The Institute welcomes your comments or inquiries. For further information. You are invited to write to: Institute of Noise Control Engineering, P.O. Box 3206, Arlington Poughkeepsie, NY 12603.

Meet The Candidates for the AAS Executive Committee Election

In July of this year an election will be held to replace seven members of the Executive Committee of the American Auditory Society. In this issue of *Corti's Organ* we have asked each candidate nominated for the office to provide the Membership of the Society with some basic bibliographic information, and to provide their thoughts regarding the future direction of the Society (A membership ballot will be mailed to you soon.)

Franklin Owen Black, M.D., F.A.C.S. Chief, Neuro-Otology Neurological Sciences Center, Senior Scientist, Neurological Sciences Institute, Good Samaritan Hospital and Medical Center, 1015 NW 22nd Avenue, Portland, OR 97210, 503-229-8159. B.A., Chemistry, Southeast Missouri State, Cape Girardeau, Missouri, M.D., University of Missouri, Columbia, Missouri, 1963.

The membership of the American Auditory Society comprises the largest cross-section of professionals in the United States who perform research, and provide service and health-care delivery to the hearing - and communicative-impaired. The Society provides a formal and informal forum for communication between professionals from very different backgrounds and perspectives. The organization of the American Auditory Society, later to become the American Auditory Society, was indeed a fortunate event because the recently increased interest of the public has facilitated efforts of the research community and the research funding organizations to respond to the rapidly increasing numbers of people of all ages with hearing and communicative disorders. Considering the considerable depth upon which it can now draw from the broadly based membership, and through consistent and energetic leadership in research and in health care delivery to patients with Communicative Disorders, the Society should continue to play a major role in charting a course which will most wisely apply the limited resources available to the cascading problems which will face both patients and professionals as the population increases and becomes older.

Deborah Hayes, Ph.D., B.S., and M.A., Northwestern University Evanston, Illinois 1971, 1973, Ph.D. Baylor College of Medicine Houston, Texas 1979, Assistant Professor, Baylor College of Medicine Houston, Texas Supervisor, Audiology Service The Methodist Hospital Houston, Texas, Department of Otolaryngology Baylor College of Medicine 1200 Moursund Avenue Houston, Texas 77030.

As the sole National society devoted exclusively to hearing, the American Auditory Society permits an unique forum for interaction among professionals with diverse backgrounds and expertise. In this time of increasing professional insularity, the Society can provide important bridges of communication among those various disciplines which have a common interest in hearing. The future strength and growth of the Society will depend, to a great degree, on its ability to encourage and promote open dialogue among its members on issues of professional controversy. The American Auditory Society can provide mechanisms not only for dissemination of scientific information, but also for discussion of basic issues impacting on our daily professional activities.

Terry Griffing, BS Univ. of Oklahoma 1956, MS Gallaudet 1959, President of Omni Hearing Systems, 2339 Inwood Rd. Dallas, Texas 75235.

First, let me say the Society by its structure, professional discipline, publications and programs offers so much. It continues to amaze me why there is not a "ground swell" of new members. The Society Beyond a doubt is the viable professional organization in the field.

Provided I was elected, and with committee approval, I would like to devote some of my energies toward an aggressive membership recruitment program. It is my belief professional growth in all our endeavors can be accelerated backed by a larger and more involved membership.

Fred M. Hughes M.S., A.B., Fresno State University, 1952. M.S., University of So. Calif., 1962. Private practice in hearing instrument dispensing, Portland, OR. 4511 S.E. Hawthorne Blvd., Ste. 215 Portland, OR 97215 (503) 238-0121.

Insofar as the rehabilitation of hearing is concerned, knowledge in related areas of science, engineering, acoustics, medicine is growing rapidly, so much so that not all of it finds immediate application. As a consequence, we still make use of systems that are probably no longer defensible. The measurement of the function of hearing leading to hearing aid selection is probably the best (and most unfortunate) example.

One of the functions of the Society should be to capitalize on the vast resources of knowledge and skills inherent in its membership to bring about an improvement in the systems presently used to alleviate hearing handicaps among those that, ineffect, constitute our "raison d'être."

Fred M. Hughes, M.S.

Robert M. Johnson, Ph.D., 1961 B.S. North Dakota State University, Fargo, North Dakota. 1963 M.A. Northwestern University, Evanston, Illinois. 1968 Ph.D. Northwestern University, Evanston, Illinois. Audiologist — Professor in Dept. of Otolaryngology, Oregon Health Sciences University. Kresge Hearing Research Laboratory 3515 S.W. Veterans Hospital Rd. Portland, Oregon 97201.

During the 1963 convention of the American Speech and Hearing Assn. in Chicago, I had the opportunity to spend an evening with several prominent audiologists of that time. The primary topic of conversation concerned the apparent need

for a professional organization devoted entirely to the ear and hearing. This organization would include members from these disciplines: Otolaryngology, Audiology, and the Hearing Aid Industry. Those ideas shortly became reality with the founding of the American Auditory Society. The need for this multi-disciplinary organization became even more important during the Hearings conducted by the Food and Drug Administration and the Federal Trade Commission. The natural tendency for each discipline to protect their "Territory" resulted in considerable conflict between members of the three groups. The opportunity for members of the three disciplines to convene and discuss common problems has significantly improved the relationships for the individual members of this organization. It also provides an important vehicle for disseminating current information regarding hearing health care to its membership.

G. Richard Holt, M.D., B.S. Zoology 1966, University of Missouri, Columbia, Missouri M.D. with clinical honors 1970, University of Missouri Medical School. Stright Surgery Internship, University of Missouri Medical Center, July, 1970-June, 1971. Resident, General surgery, University of Missouri Medical Center, July 1971-June, 1972. Resident, Otolaryngology, University of Missouri Medical Center, July, 1972-June, 1973. Chief Resident, University of Missouri Medical Center, July, 1974-June, 1975. Staff Otolaryngologist. Dwight D. Eisenhower Army Medical Center Fort Gordon, Georgia, May, 1977-July, 1978. Counselor U.S. Army Physician's Assistant Program, August, 1976-July 1978.

Philosophy on the American Auditory Society

As the acquisition of knowledge in the communicative sciences increases at a very rapid rate, the possibility exists that the dissemination of this information will be incomplete, with scattered voids in the hearing disciplines. We must be vigilant to the isolation of the basic and clinical sciences so that all attempts to integrate scientific information are made. The American Auditory Society is in a very unique position to encourage, nourish and maintain the interdisciplinary approach to the utilization of new knowledge in the communicative sciences. The cooperative spirit should be fostered by the Society and the interdigitation of information between audiologists, otologists, speech specialists, and physiological investigators reaffirmed. Our own program in San Antonio serves as an example to me of the leading role the Society can continue to take in encouraging the free interchange of ideas and technology, the complementary utilization of education and training, and the camaraderie of professionals working toward the same goal - to improve the diagnosis and care of the communicative disorders.

E. Robert Libby, O.D., Graduate Pennsylvania State College of Optometry 1948 with degree of Doctor of Optometry. President Associated Hearing Instruments, Upper Darby, Pa. Associated Professor, Department of Speech and

(Cont. pg. 4)

(Cont. from pg. 3)

Hearing, Hahnemann Medical Center, Phila., Pa. 6796 Market St., Upper Darby, Pa. 19082.

The American Auditory Society is a vital organization where workers in different disciplines of the hearing sciences have the opportunity to meet and work together toward common goals. It has been my belief that progress in the rehabilitation of person with hearing impairments can best be served by closer communication between researchers, clinicians, manufacturers, etc. in the hearing specialties. The stimulating interaction that can be achieved can promote endeavors of high technical quality.

Today, hearing aid technology has produced such developments as directional microphones, compression amplification and highly selective frequency modification. We have scarcely touched signal processing and the computer revolution. Practically any technological design is now possible. The important question is, "How do we assess psycho-acoustically the various hearing aid characteristics interacting with parameters of loudness, frequency selectivity and frequency discrimination for hearing impaired subjects?" It is hoped that the disciplinary cross pollination of the American Auditory Society and "Ear and Hearing" will bring us closer to that goal.

David M. Lipscomb, Ph.D., B.A. U. Redlands 1957 Speech Pathology. M.A. U. Redlands 1959 Speech Pathology. Ph.D. U. Washington 1966 Audiology. Professor of Audiology & Speech Pathology University of Tennessee also Director Departmental Noise Research Laboratory. Director, Rehabilitation Engineering Center for the Hearing Impaired. Department of Audiology & Speech Pathology University of Tennessee Knoxville, TN 37996.

My interest in AAS stems from the fact that it is the only organization to which I belong that offers full membership to representatives of all segments of the "hearing health community". Other groups do have associate membership categories, but I feel it is important to be on "par" with those in the medical profession, hearing aid distributors, manufacturers and representatives of manufacturers. This is not to alter the status of any one group, but to foster the appreciation by each sub-group of the value of each other sub-group, the real world situation in which we all operate contains myriad divisive elements that tend to place one professional segment in opposition to some of the others. This is true with regard to economical considerations, theoretical principles, academic factors, and even goes as far as social status. Therefore, to fulfil its purpose, AAS can do much to provide a vehicle for unification of goals of its diverse membership, thereby defeating some of these divisive elements.

Dianne J. Mecklenburg B.A. Speech Pathology Calif. State College, LA (CSCLA) 1970. M.A. - Dual: Audiology & Speech Pathology Calif. State University, LA (CSULA) 1972. Ph.D. - Audiology Bowling Green State University, Ohio (BGSU) 1978. CCC-A, 1974, CCC-Sp, 1975 Present - Private Clinical Practice and Consultant to Nucleus of Australia and Western Audiology Ltd. 295 Bellevue Drive, Boulder, Co. 80302.

The very structure of this voting system exemplifies the desire of the AAS to maintain its multidisciplinary origins. It is the only organization in the United States that promotes non-political interaction of professionals who are dedicated to all aspects of audition and provides an open forum for the dissemination of academic and non-academic information. The membership is growing; the journal is expanding to

include more basic science papers, and; the attendance at the annual meeting is increasing. In all areas the AAS is becoming more visible to the professionals. To preserve this trend it is important for the AAS to maintain flexibility in its organizational structure and thus allow for the changing needs of a Society whose management and administration hope to remain accessible to its membership.

Richard T. Myamoto, M.D., Wheaton College, Wheaton, IL. B.S. 1966. University of Michigan, Ann Arbor, MI. M.D. 1970. University of Southern California, Los Angeles, CA. M.S. (Otolaryngology) 1978. Indiana University School of Medicine Indianapolis, IN Resident in Otolaryngology 1975. Otolaryngologic Medical Group, Inc. & St. Vincent Hospital Los Angeles, CA Fellowship in Otolaryngology & Neurotology 1978. Associate Professor, Otolaryngology-Head & Neck Surgery Indiana University School of Medicine Indianapolis, IN. Chief of Otolaryngology, Dept. of Otolaryngology-Head & Neck Surgery Indiana University School of Medicine. Chief of Otolaryngology-Head and Neck Surgery Wishard Memorial Hospital, Indianapolis, IN. Board of Governors, American Academy of Otolaryngology-Head & Neck Surgery. Secretary-Treasurer, Indiana Academy of Otolaryngology-Head & Neck Surgery. Vice-President, Alumni Fellowship Group of the House Ear Institute, Los Angeles, CA.

As a practicing otologist I recognize the acute need for a multiple disciplinary approach to problems of hearing, hearing preservation, and the rehabilitation and habilitation of hearing impaired individuals. It is extremely gratifying to observe the tremendous refinement in diagnostic techniques and the advances in the medical and surgical treatment of hearing loss. However, there remains a large population who cannot be helped by means currently available in the otologist's armamentarium. On going research in closing this gap but more than ever before, if further progress is to be made, a free interchange of ideas between the various disciplines represented in the membership of the American Auditory Society must occur. I perceive the American Auditory Society as a key organization in insuring that this progress will continue.

Michael F. Seidemann, Ph.D., 1968 - Bachelor of Science - Old Dominion University Major: Psychology. 1969 - Master of Science - Old Dominion University Major: Psychology. 1973 - Doctor of Philosophy - Florida State University Major: Audiology. Professor of Audiology and Otorhinolaryngology. Department of Audiology and Speech Pathology LSU Medical Center 100 S. Derbigny Street New Orleans, LA 70112.

In a very brief period of time the American Auditory Society has achieved a leadership position as an interdisciplinary specialty organization. Such achievement can be directly attributed to quality leadership and publications. I feel that such successful direction should be maintained in the future, and not altered. Audiologists, otologists, hearing aid specialists, and other allied professionals have needed a forum such as the American Auditory Society provides for many years. At the annual meetings, as well as in the Auditory Society's journals we have been able to set aside professional differences and exchange information and ideas for the benefit of the hearing impaired.

I feel that the American Auditory Society in the future should continue along its present course, remain apolitical, and strive to encourage advances in the medical, prosthetic and educational prevention and treatment of hearing loss.

Richard J. Salvi, Ph.D., Associate Professor, University of Texas at Dallas Callier Center for Communication Disorders, 1966 Inwood Road Dallas, Texas 75235. B.S. North Texas State University Psychology 1969. Ph.D. Syracuse University 1975 Psychology. NIH post-doctoral fellowship University of Medical Center, State University of New York 1976. State University of New York regarding the American Auditory Society.

Clinical and basic research in hearing and speech has changed enormously in both quantity and scope during the past decade. Each passing year sees the introduction of a new journal or society created to bypass the publication bottleneck and provide a forum for a new or specific line of research. The proper information at the right time has never been greater. The American Auditory Society grew out of a need. The Society's growth over the past three years attests to its success at providing relevant information to a number of clinicians, physicians and educators interested in the assessment, diagnosis and treatment of hearing disorders and in understanding the process of hearing. During the decade, the Society and its journal, Ear and Hearing, have challenged to keep pace with the communication information revolution. We are already witnessing significant change. Manuscripts and documents are typed on computers and information is transmitted on floppy discs or over telephone lines; type setting is done in front of a terminal; computers and information is transmitted on a terminal; computers help us search for relevant journal articles. We are likely to see more dramatic changes. Journals may be displayed on video terminals and we may attend Scientific Meetings with the aid of closed circuit television. The Society must keep abreast of the technology in order to grow and meet the future needs of its members.

Wayne J. Staab, Ph.D., A.B. Degree, Fort Hays State University, 1963. M.S. Degree, University of Wisconsin-Madison, 1965. Ph.D. Degree, Michigan State University, 1971. Vice President, Marketing, Audiotone, 2422 West Holly, Phoenix, Arizona 85009.

The American Auditory Society should continue the role expressed in Article 2 of the AAS Statutes. It should provide a nonpolitical independent medium for interaction of multidisciplinary membership and continue to pursue a variety of membership consistent with the goals of the AAS...persons with different credentials, roles and expertise. It is this diversification that sets AAS apart from any other organization in dealing with the human hearing process and its rehabilitation.

The future of AAS lies in the assumption that no single educational background will govern the group's interests. The organization should continue to provide a non-political forum where the various specialty backgrounds can exchange viewpoints, and concerns of mutual interest. With this in mind, I believe that some effort should be made to involve those AAS members more fully who do not comprise the largest membership segments — audiologists and otolaryngologists.

(Cont.)

James J. Pappas, M.D., B.S. degree in 1954 from the University of Arkansas, followed by an M.D. degree from the same in 1956. My otolaryngology residency training was taken at Baylor University College of Medicine from 1960 to 1963.

I am a strong supporter of the stated aims of the American Auditory Society and look to Society meetings, publications and other forms of communication as an outstanding opportunity for all professionals involved in the study of hearing and the rehabilitation of hearing disorders to improve their knowledge of related disciplines and have an open exchange of ideas and experiences. As an otologist, I understand the importance of communicating with professionals in such fields as audiology, psychoacoustics, engineering and deaf education because of the increasing complexity of knowledge in each of these areas.

I see the American Auditory Society in the future as a forum of ideas from many disciplines, each serving to stimulate research and to improve provision of care to patients through all disciplines involved.

Jerome Goldstein, M.D. to join Academy Staff as EVP Designate

Dec. 27, 1982: The American Academy of Otolaryngology – Head and Neck Surgery, Inc. has announced that Jerome C. Goldstein, M.D. will join its staff Jan. 1, 1983 as Executive Vice President Designate. The current Executive Vice President, Harry W. McCurdy, M.D., plans to retire December 31, 1983.

Dr. Goldstein comes to the Academy with a broad background in otolaryngology. At Albany Medical College, his current position is Professor and Head, Division of Otolaryngology. Previous to that he was in private practice. He is also a Director of the American Board of Otolaryngology and a member of its Examination Committee.

Dr. Goldstein has served on the Academy's Committees on Drugs, Surgery of the Head and Neck, and Pathology as well as on the Continuing Education Course faculty. He served on the American Council of Otolaryngology's Board of Directors and was Chairman of its Professional Relations and Public Education Committee.

Dr. Goldstein is currently President of the American Society for Head and Neck Surgery. He is also a member of numerous national societies including the American College of Surgeons, the American Academy of Facial Plastic and Reconstructive Surgery, and the Triological Society.

Dr. Goldstein has been very active in county and state medical societies. He is the immediate past president of the Eastern New York Ophthalmology and Otolaryngology Society and served from 1975-81 as Secretary of the New York State Society of Otolaryngology – Head and Neck Surgery. Dr. Goldstein is currently on the Board of Northeastern New York Blue Shield. He is a member of the Executive Committee and New York State Chairman of the Centurions of the Deafness Research Foundation. He also serves on the editorial boards of three national medical publications: Annals of Otorhinolaryngology, Archives of Otolaryngology, and Comprehensive Therapy.

The American Academy of Otolaryngology – Head and Neck Surgery, Inc. was established in Jan. 1982 as a result of the merger of the American Council of Otolaryngology – Head and Neck Surgery and the predecessor Academy. Unified, the new Academy comprises the largest scientific/educational society of otolaryngologists in the U.S. Located in Washington, D.C., it also represents otolaryngology – head and neck surgeons (formerly known as ear, nose and throat doctors) in governmental affairs.

"Information, Awareness and Understanding for Integration" Chosen as Theme for 1984 World Congress of Rehabilitation International

One of Europe's most beautiful and hospitable cities, Lisbon Portugal, will be the gathering point for thousands of disability specialists, June 4-8, 1984. The historic port will be the site for the Fifteenth World Congress of Rehabilitation International.

The theme of the Congress is "Information, Awareness and Understanding for Integration of Disabled Persons and Society." The attached Congress Symbol represents the four points of the theme.

Col. Joao Villalobos Vieira, Director of the host organization, the Portuguese National Secretariat for Rehabilitation, was confided as Congress President by the 1982 meeting of the Rehabilitation International Assembly. He is also the founder of Portugal's meeting national association of people with physical disabilities.

A preliminary Congress program, developed by the Rehabilitation International Secretariat, develops the theme through examination of ways that information activities, the mass media and innovative service programs can advance the integration of people with disabilities and their societies. The program includes plenary addresses, workshops organized by the seven standing commissions of Rehabilitation

International; sectoral meetings organized with the cooperation of organizations representing people with disabilities; and poster sessions on various topics.

A Congress folder has just been published and is available from:

Secretariado Nacional
de Reabilitacao
Av. Conde Valbom, 63-5
1000 Lisbon, Portugal

(Rehabilitation International is a federation of 135 member organizations providing services to people with disabilities in 77 countries. It has official relations with the U.N. Economic and Social Council, UNESCO, the International Labor Organization, the World Health Organization, UNICEF and regional bodies including the Council of Europe, the Commission of European Communities and the Organization of American States. Its seven standing commissions work on specialized aspects: medical; vocational; education; social; technical aids, buildings and transportation; organization and administration; and leisure, recreation and sports. Founded in 1922, R.I. has held 14 quadrennial world congresses, 10 regional conferences and many specialized international meetings.)

Just Like Home

A home-like setting facilitates on-the-spot evaluation of many aids selected by clients of the hearing clinic.

Sheila Gottlieb, graduate student in audiology, works with a client in the new home-environment room.

A gray-haired man and a young woman sit chatting and sipping coffee at the dining table. Ignoring the sound of the dishwasher and the laughter – and arguments – of children at play, the two remain intent on their conversation. It's a scene typical of many a family home, but this setting is actually part of the hearing clinic in Purdue's Department of Audiology and Speech Sciences.

"The idea is to recreate a home environment," Dr. Carl Binnie, professor of audiology and speech sciences, explained. "The kitchen, living room and dining room form different settings for one-on-one, small-group or large-group communication. In this new room we can evaluate an individual's ability to communicate in a true-to-life situation."

The special room looks like a compact efficiency apartment with kitchen, dining and living areas. The difference is that the noises of the dishwasher, television, garbage disposal and other appliances are pre-recorded and can be turned on or off at will. Even the sounds of children playing or of a large group talking are recorded and come from strategically placed speakers in the corners of the room. The flexibility of the setting permits audiologists to simulate situations that might produce special problems, and then to discuss solutions to those problems, before they pose actual social difficulties for the hearing-impaired.

The clinic does comprehensive hearing testing and is equipped to dispense, adjust, check and repair hearing aids as well as to make ear molds. In fact, the clinic has a full range of hearing aid models for clients to examine and try, but clinic services go far beyond this basic diagnostic step.

"It's important that the person with a communication problem be able to interact in their own life situation," Binnie commented, "not just under ideal conditions." Some clients

may need a visual alert to replace the ring of the doorbell, phone or alarm clock. Others may need one of several types of adapters in order to be able to hear television sounds clearly. Those with serious problems may need closed circuit captioning units for their television sets or TDD systems to permit them to send and receive typed messages through the phone system. These devices, too, are available for inspection and trial use at the center.

Technology can solve only part of the problem for the hearing-impaired, and the total rehabilitation program stressed the importance of the human factor in improving communication ability. Whether the client is a baby or an octogenarian, the clinic has a program tailored to the person's needs. A parent-infant program teaches parents how to aid the language development of their hearing-impaired child. A preschool program for children three to five years of age offers two options. One service emphasizes auditory training and speech development; the other teaches the child to utilize all modes of communication including sign language. Parents of children in both programs are involved in a parallel counseling program. A schoolage program provides consultation and support services for children and their teachers in regular and special education classes, and an adult communication skills program offers a group program on hearing aid use and communication strategies, as well as individual auditory training and family counseling services.

Hearing aids are the first, not the final step in rehabilitation. The new home environment facility in AUS takes the rehabilitation effort into an important area, a place just like home.

(Ed. note: This article previously appeared in a recent Purdue University Newsletter.)

DON'T KID AROUND WITH PEDIATRIC TESTING

THE CYBERSMITH VRA SYSTEM V PEDIATRIC TEST SYSTEM

EACH CYBERSMITH SYSTEM V INCLUDES: 2-ANIMATED REINFORCEMENT TOYS IN LIGHTED, SMOKED ACRYLIC PLASTIC CABINETS, 1-CENTER FIELD REINFORCEMENT TOY IN CLEAR PLASTIC CABINET, 1-POWER SUPPLY/CONTROL CONSOLE, 1-HAND-HELD REMOTE CONTROL UNIT, 1-CHILD RESPONSE "BUTTON," 1-JACKBOX, ALL CABLES AND HARDWARE.

FEATURES

- VERSATILITY: VROCA / COR / VRA
- THREE TOYS INSTEAD OF TWO (ONE FOR CENTER SOUND FIELD ORIENTATION)
- REMOTE CONTROL TO ALLOW SOLO TESTING. ESSENTIAL FOR PRIVATE PRACTICES
- SELECTABLE REINFORCEMENT (LIGHTS ONLY OR LIGHTS PLUS ANIMATION)
- RUGGED ATTRACTIVE CONTROL CONSOLE
- RELIABLE HEAVY DUTY SOLID STATE POWER SUPPLY
- PLUG-IN INSTALLATION (NOTE: WALL MOUNTING IS RECOMMENDED. MOUNTING HARDWARE IS INCLUDED)
- DESIGNED BY PRACTICING CLINICIANS FOR PRACTICING CLINICIANS

Convention Reminder

The 10th Annual Meeting of the American Auditory Society will be held in Cincinnati, Ohio on November 17, 1983, in the Convention Center, downtown Cincinnati. A block of rooms has been reserved in the nearby Netherland Plaza Hotel. A hotel reservation form is below. Please note that this year's meeting will be held the day before the Annual Convention of the American Speech-Language-Hearing Association. You are encouraged to make your hotel reservation early, and to note on the reservation form your final departure date.

This year's annual banquet will be held at Forest View Gardens, an authentic "gastehaus" in the tradition of Cincinnati's German heritage. With music provided by the singing waiters and waitresses from the University of Cincinnati college Conservatory of Music, this promises to be a very cordial evening.

RESERVATION REQUEST FORM FOR AMERICAN AUDITORY SOCIETY AT NETHERLAND PLAZA HOTEL

ARRIVAL DATE: _____ TIME: _____ *DEPARTURE DATE: _____

TYPE OF ROOM:
Single at \$58 per night
Double (2 persons, one bed) at \$70 per night
Twin (2 persons, 2 beds) at \$70 per night

Mail to:
NETHERLAND PLAZA
Reservation Department
35 West Fifth
Cincinnati, OH 45202

LAST NAME: _____ FIRST NAME: _____

COMPANY NAME: _____

ADDRESS: _____

CITY: _____ STATE: _____ ZIP CODE: _____

Rooms are held until 6:00 p.m. unless later time of arrival indicated. Your reservation can be guaranteed by a major credit card and your authorization to bill you for the first night if you should not arrive. Cancellations are accepted until 6:00 p.m. on the day of your arrival.

CREDIT CARD COMPANY: _____ NUMBER: _____

SIGNATURE: _____ EXPIRATION DATE: _____

NOTE: Regular check-in time is 3:00 P.M.

*If you plan to stay through ASHA, please indicate your final departure date. Reservations to the AAS meeting are required to be made before November 1, 1983.

Summer/Fall 1983

Program Committee Outlines Outstanding Program - Harris Titles Talk

DALLAS, TX AUGUST 23, 1983. The 1983 program committee, chaired by Dr. Robert W. Keith, met in Cincinnati on August 5th and reviewed the many submitted papers to finalize this year's program. Over 35 papers were received, making it one of the most successful call for papers in the 10 years that AAS has been in existence. The final program is published in this issue of Corti's Organ on page 3, and abstracts of the papers begin on page 4. Keith and the other members of the program committee that were able to attend the meeting, Drs Robert Glaser and Kenneth Donnelly, all agreed that this year's selection of papers was very high in quality and making the final selection was no easy task.

A special event during the meeting will be the presentation of the Belton Distinguished Teaching Award (see details this page). Also, after the meeting those interested can join in on the festivities at the Forest View Garden where there will be an evening of sumptuous dining and lively entertainment. Tracoustics, Inc. has agreed to provide transportation of AAS members and others attending the meeting from the convention center to this landmark restaurant in the old historic part of Cincinnati.

Dr. J. Donald Harris is this year's Carhart Memorial Speaker and will address the society on the topic "The World of Hypoacusis." In traditional style Dr. Harris, when writing to give the title of his talk stated, "Many writers and editors use 'hypacusis' but it lately seems to me to be an ambiguous elision also for 'hyperacusis'. Also, I don't hesitate to turn an adjective into a noun. A more conventional reading might be 'The World of Hypoacuisa', but I prefer the more personal tone as in the title I chose." Those of us who know Dr. Harris are anxiously awaiting his stimulating discussion on this topic.

This year will be the best meeting yet, and it is hoped that each and every one of the AAS members will be able to join the group for the excellent papers, renewal of old acquaintances, and evening festivities.

J. Donald Harris

And The Winner Is ...

Beltone Electronics Corporation will name the winner of the second annual Beltone Distinguished Teaching Award in Audiology at the AAS Convention in Cincinnati, November 17.

Mr. Charlie Anderson, president of AAS, extended the invitation to Beltone President Lawrence M. Posen in recognition of the AAS goal of bringing together all facets of the hearing health care team, including audiologists, physicians, dispensers, educators, students and manufacturers. The AAS Convention will be held at the downtown Cincinnati Convention Center, in conjunction with the annual Convention of the American Speech-Language-Hearing Association.

Posen accepted the invitation on behalf of Beltone and commended the American Auditory Society for their goal of increasing the knowledge of human hearing, promoting conservation of hearing, and fostering habilitation and rehabilitation of the hearing impaired.

The Belton Distinguished Teaching Award in Audiology is given annually by Beltone to an outstanding audiology instructor in the United States or Canada. Candidates are nominated by an audiology student or graduate. The intent of the award is to honor the teaching profession for the vital role it plays in shaping the future of the field of hearing technology for the hearing impaired.

Twenty-eight instructors are competing for this year's award. A monetary gift and a grant for the winner's school goes with it, as well as the opportunity for the winner to present his or her audiological research papers before a variety of professional forums. Judges in the competition are prominent educators and other professionals from the field of audiology.

Reger To Be Honored By Symposium

A symposium to honor the memory of Scott N. Reger will be held at the University of Iowa from April 12-14 1984. The symposium will focus on "Sensorineural Hearing Loss: Mechanisms, Diagnosis and Treatment," and will be sponsored jointly by the Department of Otolaryngology-Head and Neck Surgery and the Department of Speech Pathology and Audiology. The program will be directed by Arnold M. Small, Jr., Ph.D., M. Jane Collins, Ph.D., and Lee Harker, M.D., and will include approximately 20 guest speakers. Issues to be addressed include those in both the basic sciences and clinical management. Further information may be obtained by contacting M. Jane Collins, Ph.D., Wendell Johnson Speech and Hearing Center, University of Iowa, Iowa City, Iowa 52242.

Dr. Reger was a past member of AAS and a Carhart Memorial Award Winner.

1983 Convention

Registration Form pg. 8

HIA Special Report

WASHINGTON, D.C., May 2, 1983 - The Hearing Industries Association (HIA) today announced the Association's Standing Committees for the current year.

HIA President James C. Keyes, Audiotone, announced the formation of an HIA Membership Committee, charged with expanding the Association's membership among hearing aid manufacturers, distributors, component manufacturers, earmold laboratories and suppliers. Jerry G. Johnson, Oticon Corporation, was named by Keyes to chair the Membership Committee. Members of the committee are: Glenn L. Kennedy, Hearing Services, Inc.; Reginald Garratt, Knowles Electronics, Inc.; and William D. Hooper, Unitron Industries, Inc.

Additionally, President Keyes named the 1983 Market Development Committee, which will elect its own chairman at its first meeting, to be held in early summer. Members appointed to serve on the Market Development Committee are: Wayne J. Stabb, Audiotone; John J. Zei, Beltone Electronics Corporation; Marjorie D. Skafte, Hearing Instruments; Reginald Garratt, Knowles Electronics, Inc.; and Jerry G. Johnson, Oticon Corporation. Carole M. Rogin continues as HIA's Director of Market Development.

The HIA Standards and Technical Committee continues under the chairmanship of Harry Teder, Telex Communications, Inc. Additional committee members include: James Nunley, Audiotone; Richard Brander, Beltone Electronics Corporation; Ole Arndt, Bosch Hearing Instruments; Elmer Carlston, Industrial Research Products; Praben Brunved, Oticon Corporation; Mark Gorder, Resistance Technology; David Preves, Starkey Laboratories, Inc.; and Horst Arndt, Unitron Industries, Inc.

Swedish Audiologist Joins The University of Minnesota

Gunnar Liden, professor of audiology and otolaryngology at the University of Goteborg in Goteborg, Sweden, and head of the audiology clinic at Sahlgrenska Hospital, also in Goteborg, will be joining the faculty of the University of Minnesota's department of otolaryngology as a visiting professor beginning September 1, 1983, staying for a minimum of two years. He will be teaching and collaborating on research projects with Michael Paparella, M.D., professor and chairman of the department of otolaryngology and Earl Harford, Ph.D., director of audiology in the department.

Liden's main research efforts while at the University will be in the area of amplification for the hearing impaired. Liden, 65, is one of the pioneers of impedance audiometry and published the first article on tympanometry to appear in an American journal. The author of nearly 300 works in professional and scientific publications, Liden also developed Swedish speech audiometry and did early work on a pediatric test battery, including visual reinforcement audiometry. Married and the father of one daughter, Liden will retire from the University of Goteborg as the head of the world's largest audiology center on July 1, 1983.

Gunnar Liden

Letter From England

Dear Editor,

The recent splendid issue of Corti's Organ has reminded us of the pleasures of attending a scientific meeting in the USA. It has provided some striking evidence of the progress of audiological research to which you and your colleagues have made many valuable contributions.

I have noted with particular interest the abstracts of papers with a strong pathological bias. With reference to Dr. Abramson's valuable studies on cholesteatoma two papers from London on this important topic might be of interest to your readers. Drs. Wells and Michaels from my old department described the histopathological features of retraction pockets and Dr. Brookes from Dr. Morrison's department at the London Hospital three cases of Post-traumatic cholesteatoma. These papers published in Clinical Otolaryngology lend further support, if such is needed, to the immigration or implantation theory this writer has considered the commonest mechanism in the pathogenesis of epidermoid cholesteatoma.

The other abstract that has attracted my attention was Dr. Peck's report on hearing problems of children with mucopolysaccharidosis II (Hunter's syndrome). This problem and, in particular, the related Hurler's syndrome has been intensively studied by a team of the Metabolic Disorders Division (Director, Dr. Watts) at our Northwick Park Hospital and Clinical Research Centre.

Such children suffer from conductive deafness and sensorineural deafness. Another example of the greater awareness, also in Europe, of the importance of otological and audiological research is the organization and coordination of temporal bone studies by a Subcommittee of the European Community - incidentally inspired by your friend Dr. Ole Bentzen from Denmark. A detailed book of instructions on 'Functional Histopathology of the Human Audiovestibular organ' has been compiled by several well-known authors in this field and edited by Professor Salvatore Iurato (Italy); Dr. Goran Bredberg (Sweden) and Dr. G. Bock (England). This will be available to pathologists and ENT-Surgeons and should contribute, as in the USA, to our knowledge of the pathology of the ear.

In my last letter I have noted that the Journal of Laryngology will be appearing in an attractive new format. This has been well received, moreover the Journal is going to be expanded by about 20 pages an issue. This should allow us to reduce the ever lengthening waiting period inspite of the monthly publication of our Journal. I congratulate you that you too are planning a more frequent publication of Corti's Organ.

I have had the privilege of being an enthusiastic witness of the transformation of otorhinolaryngology in the last thirty years. Who would have expected in 1953 that a Conference on Otitis Media would attract 170 or more papers in 1983! I did and I might do a little reminiscing next time I write to you.

I. Friedmann

Seventh Shambaugh/Shea International Workshop On Otology

MARCH 1-4, 1984

SPONSORED BY THE NATIONAL HEARING ASSOCIATION

(Oak Brook, IL) An outstanding faculty of 50 world renowned experts in Ear Surgery and Neurotology will lead this workshop series. Emphasis will be placed on new and current medical techniques in the field of hearing. Optional evening programs have been arranged for review and medical/surgical controversies. The Workshop will be held at the Chicago Marriott Hotel. CME accreditation will be extended to those in attendance at the Workshop.

To apply contact:

National Hearing Association
1010 Jorie Blvd., Suite #308
Oak Brook, IL 60521

AAS ANNUAL**MEETING**

NOV 17th, Cincinnati

Berger Prescription**Method Materials**

Several new materials are now available to assist clinics in using the Berger Hearing Aid Prescription Method.

AUDIO CASSETTES. The method is described on three minute audio cassettes. The procedures are presented detail on the cassettes, and the materials are designed individual study or class use. The cassettes are available loan for one week for a small rental fee. To schedule write: Kenneth W. Berger, Speech & Hearing Clinic, Kent State University, Kent, Ohio 44242. Or call, (216) 672-2111.

PERSONAL COMPUTER PROGRAM AND CASSETTE TAPE. Two programs for personal computers with prescription are available, both on cassette tape along with written instructions and program listing. The "PC" (Personal Computer) program may be used with either the Radio Shack TRS 80 PC-1 or Sharp PC-1211. The "Z-16" program is used with either the Sinclair ZX 81 or Timex-Sinclair TS 1000 v external 16K (RAM) pack. For further details write: D. Services, 213 34th Street, West Des Moines, Iowa 50265.

WRITTEN COMPUTER PROGRAM. The prescription program is also available in an extended written-only version in BASIC and in FORTRAN. For further information write: Kenneth W. Berger, Speech & Hearing Clinic, Kent State University, Kent, Ohio 44242.

HEARING AID SELECTION GUIDE. This slide chart permits rapid and accurate determination of predicted air thresholds, and the maximum gain required to approximate those thresholds. For further information write: Association of Hearing Instruments, 6796 Market Street, Upper Merion, Pennsylvania 19082.

Screening Information Available

Impedance screening, a new concept in hearing screening that many schools and preschool programs are now implementing, has great promise for preventing learning problems. The H.E.A.R. Program in Newton, Massachusetts has been working for five years to perfect and test a training/diagnostic management system to facilitate the use of a combination of pure tone and impedance screening. They have available a packet of information about impedance screening, the effects of hearing loss, and impedance programs in schools. To receive this folder of information, write to John Roberts, Coordinator, H.E.A.R. Program, Metropolitan Centers, 181 Wells Avenue, Suite 204, Newton, MA 02159. In addition, you may ask to receive their quarterly newsletter "Speaking of Hearing," at no cost. If you have questions regarding impedance screening, call the H.E.A.R. Program on their toll-free lines (1-800-225-4270 or 1/800/225-4271).

1983 AAS PROGRAM SCHEDULE
CINCINNATI CONVENTION CENTER THURSDAY, NOVEMBER 17

8:30-8:40 Introductory Remarks

10:50-11:00 Discussion

3:06-3:18 A Clinically Manufactured Stepped-Diameter Earmold for Superior Aided Listening. (Valente)

Topic: Auditory Brainstem Response

8:40-8:52 Auditory Brainstem Response Stimulus-Related Variations as a Prediction Method of High Frequency Hearing Loss. (Balzer)

8:52-9:04 Reliability of Auditory 40-Hz Event Related Potential Measures. (Lesner, Lynn and Poelking)

9:04-9:16 Clinical Use of Electrocochleography. (Lewis and Whitaker)

9:16-9:23 Discussion

9:28-9:40 The Relationship Between Acoustic Neuroma Size, Auditory Brainstem Response, Acoustic Reflex Findings and Hearing Loss. (Rudin and Coleman)

9:40-9:52 The Differential Effect of Barbituates on Auditory Brainstem vs. Middle Latency Evoked Responses: A Clinical Study. (Hall, Allen and Hargadine)

9:52-10:02 Discussion

Topic: Differential Audiology

10:02-10:14 The Results of Three Dichotic Speech Tests on Subjects with Brainstem and Hemispheric Lesions. (Musiek and Rackliffe)

10:14-10:26 Interpreting Central Auditory-Language Processing Test Results In Children. (Lucker)

10:26-10:38 Neurophysiological Correlates of Specific Learning Disabilities. (Staller)

10:38-10:50 Use of NU-6 Word Lists in Rollover Measurement. (Meyer and Mishler)

11:00-11:45 Carhart Memorial Lecture

"The World of the Hypoacusic." J.D. Harris

11:45-12:00 Presentation of the Beltone Distinguished Teaching Award

12:00-1:10 Lunch Break

1:10-1:30 Business Meeting

Topic: Pediatric Audiology

1:30-1:42 The Natural History of Supra-High Frequency Hearing in Children 8-18 Years of Age. (Downs, Fletcher, Lampe Doster and Simonton)

1:42-1:54 Retrospective Study of the Etiology of Hearing Loss in Children. (Shimizu and Erskine)

1:54-2:06 Responses of Newborns to High Pass Filtered Noises. (Gerber and Dobkin)

2:06-2:18 Discussion

2:18-2:30 Crib-O-Gram and Auditory Brainstem Response: Direct Comparison of Two Infant Hearing Screening Methods. (Kuklinski and Hosford-Dunn)

2:30-2:42 A Description of the Results of the Past Five Years of a High Risk Hearing Screening Program. (Moneka and Gollegly)

2:42-2:54 Discussion

Topic: Hearing Aids

2:54-3:06 Performance Characteristics of Hearing Aid Compatible and Incompatible Telephone Receivers. (Gladstone and Kahl)

3:18-3:30 Discussion

Topic: Tinnitus

3:30-3:42 Auditory Electrical Stimulation: Effects on Tinnitus. (Edgerton, McElveen and Brimacombe)

3:42-3:54 Tinnitus Evaluation and Treatment. (Johnson, Vernon, Meikle and Brummett)

3:54-4:06 Pilot Study on the Effects of a Group Intervention on Normal-Hearing Subjects Suffering from Handicapping Tinnitus. (Normandin, Roberge and Bergeron)

4:06-4:16 Discussion

Topic: Rehabilitation

4:16-4:28 Options for the Profoundly Deaf: An Outgrowth of the Cochlear Implant Project. (Pope, Miyamoto, Shallop, Kienle, McKonkey and Young)

4:28-4:40 Test/Re-Test Reliability of the Hearing Handicap Inventory for the Elderly. (Weinstein, Ventry and Spitzer)

4:40-4:52 An Articulation Index Study of Phonemic Regression in the Elderly. (Parlovich and McCroskey)

4:52-5:02 Discussion

5:02-5:15 Closing Remarks

6:30-6:45 Load Busses to Forest View Gardens (Transportation provided by Tracoustics, Inc.)

7:00-? Dinner at Forest View Gardens

TENNIS OR JOGGING ANYONE?

If you have a hearty disposition and want to join a group of enthusiastic AAS members in a little jog (about 2 miles) or Tennis match the morning of Nov. 17th at 6:00 a.m. (can you believe it), Contact Robert Glasier (111 W. First St., Suite 412, Dayton, Ohio 45402) for tennis or Ross Roeser (1966 Inwood Road, Dallas, Tx 75235) for the jog if you are interested.

On April 27th, at the Milan Press Club, Prof. W.D. Keidel of Erlangen University was awarded the Amplifon Research and Study Center International prize for 1982 in recognition of his scientific achievements in the fight against deafness.

1983 PROGRAM ABSTRACTS

(FOLLOWS CONVENTION SCHEDULE ON PAGE 3)

AUDITORY BRAINSTEM RESPONSE (ABR) STIMULUS-RELATED VARIATIONS AS A PREDICTION METHOD OF HIGH FREQUENCY HEARING LOSS

Gene K. Balzer Department of Neuro-Diagnostics
Bismark Hospital Bismark, ND

This study investigated the characteristic variations of morphology, amplitude and latency of high frequency hearing loss subjects as compared to age and sex matched normal hearing subjects for the Auditory Brainstem Response (ABR). Single sine wave acoustic transients with center frequencies below the cutoff frequency of the high frequency hearing loss (1,000 Hz) and within the frequency range of the high frequency hearing loss (8,000 Hz) were presented at 40 dB nHL and 70 dB nHL to yield ABR results which were described with regard to morphology, amplitude, latency and stimulus phase latency differences. Statistically significant variations in a) morphology (absences of P1 and P3 component waveforms), b) amplitude (increased P5:P1 relative amplitude ratio), and c) absolute latency (accelerated P5 latency/intensity functions) were demonstrated in the high frequency hearing loss subject as compared to the normal hearing subjects. No statistically significant interpeak latency variations were noted. Additionally, no statistically significant absolute latency differences in component waveforms were observed for condensation as opposed to rarefaction initial stimulus phase signals. Examination of ABR results suggested that by utilizing the previously mentioned morphology and latency variations as identification criteria, 90 percent of the high frequency hearing loss subjects in this sample would be identified as such and none of the normal hearing subjects would have been incorrectly identified as at risk for high frequency hearing loss (false positive). These two variations of a) absence of P1 and P3 component waveforms in the 8,000 Hz, 40 dB nHL condition and b) P5 latency intensity function of greater than .06 msec/dB in the 8,000 Hz 40 dB and 70 dB nHL, are suggested as an ABR protocol for screening for high frequency hearing loss in patients difficult to behaviorally test.

RELIABILITY OF AUDITORY 40-HZ EVENT RELATED POTENTIAL MEASURES

Sharon A. Lesner, James M. Lynn and Sharon S. Poelking
University of Akron
Akron, Ohio

Galambos, Makeig, and Talmachoff (1981) described a procedure, the 40Hz event-related potential (40-Hz ERP), for recording the auditory middle-latency response potentials. This procedure was demonstrated by Lynn, Lesner, Poelking, and Daddario (1982) to be a reasonable accurate and effective way to predict behavioral thresholds for 500 and 1000 Hz in a population of hearing-impaired adults. The present study examined the reliability of the 40 Hz ERP procedure in estimating hearing sensitivity. Thresholds for the 40-Hz ERP were obtained from 40 ears with cochlear hearing loss for 500 and 1000 Hz signals on two separate occasions. Stimuli consisted of tone pulses with rise/fall times of 5 msec, delivered at a rate of 39.1 per second and referenced, in level, to 0 dB nHL. Potentials were amplified by 104 and 600 responses were averaged with a Nicolet CA-1000 averager triggered externally with a Nicolet 502 pulse generator. A minimum of two replications was obtained for each signal condition.

The 40-Hz ERP thresholds were established by an investigator who was unfamiliar with any of the hearing-impaired subjects. Each subject's behavioral thresholds for pure tones were then determined by an investigator other than the one who obtained the 40-Hz ERP thresholds. After a period of approximately four months, subjects were retested following the same procedures.

The test-retest reliability coefficient for 500 Hz was 0.87 (p.0005) and for 1000 Hz it was 0.51 (p.05). Ramifications concerning the feasibility of using 40-Hz ERP as a frequency specific predictor of hearing sensitivity will be presented.

CLINICAL USE OF ELECTROCOCHLEOGRAPHY

Anne E. Lewis and Samuel R. Whitaker
Los Angeles Ear Medical Group, Inc.
Los Angeles, California

In our private otologic clinic, we are using electrocochleography as part of a diagnostic evaluation of patients with Meniere's disease or endolymphatic hydrops. In the past, clinical electrocochleography (ECoG) was limited primarily by difficult recording techniques, i.e., transtympanic recordings which requires an otologist present to insert the electrode. When Coats introduced the "plastic leaf" extratympanic

ic electrode, a non-invasive procedure, ECoG became a more clinically feasible test. Disadvantages of the plastic leaf electrode, however, include high electrode impedance, some skill required for proper insertion and occasional patient discomfort. Our clinic has designed an extratympanic electrode which overcomes the problem of high electrode impedance, is simple to insert and causes little, if any, patient discomfort. Primarily we are recording the summing potential (SP) and the whole nerve action potential (AP) and measuring the amplitude ratio between the two potentials. It has been shown that responses recorded from a patient with Meniere's disease often exhibits an enhanced SP and the results from our clinic support this finding. We have observed the enhancement of the SP to vary with patient symptomatology and we have monitored and found the enhancement of the SP to improve during glycerol dehydration, which supports the hypothesis that changes in intralabyrinthine pressure and volume will produce variations in the enhancement of the SP. In conclusion, by using a noninvasive recording technique, electrocochleography is a relatively simple procedure to administer and provides valuable information in the diagnosis and monitoring of Meniere's patients.

THE RELATIONSHIP BETWEEN ACOUSTIC NEUROMA SIZE, AUDITORY BRAINSTEM RESPONSE, ACOUSTIC REFLEX FINDINGS AND HEARING LOSS

Stephanie Rudin and John Coleman
Otologic Medical Group, Inc.
Los Angeles, California

The purpose of this study is to evaluate in greater detail the diagnostic correlation between auditory brainstem response, acoustic reflex findings, hearing loss, and acoustic neuroma size. Specifically, our diagnostic interest is to identify these lesions as early as possible. With the detection of smaller neuromas comes the reduced risk of damage to the Facial Nerve during surgery and makes available the possibility of preserving hearing in the affected ear using the middle fossa approach. A greater number of small tumors are identified presently, due to the advent of the CAT scan. One of our goals is to establish more sensitive criteria for detecting smaller tumors in an effort to maximize our effectiveness and efficiency at the clinical level.

Currently used assessment criteria such as asymmetrical hearing loss, reduced discrimination or abnormal acoustic reflex findings at 500 or 1000 Hz are not adequately sensitive clinical measures for identifying smaller lesions. We have found that these manifestations are much less prevalent in smaller tumors. It appears that larger acoustic neuromas exhibit a wide range of hearing loss. Patients with smaller lesions typically have audiograms showing thresholds within normal limits or mild losses.

Criteria currently used in acoustic reflex testing enables the detection of larger tumors, while having a high false-negative rate for smaller lesions. Coleman & House (ASHA 1982) revised these criteria to include abnormalities observed at 2000 and 4000 Hz. A relationship appeared to exist between tumor size and the frequency at which acoustic reflex abnormality occurred.

Auditory brainstem response results have shown P5 values to be either delayed or absent in the presence of Eighth Nerve lesions. Sellers & Brackmann (1979) found a trend toward larger acoustic neuromas having greater difference between affected and unaffected ear for P5 (IT5). However, a correlation was not examined.

In this study, thirty patients with surgically confirmed acoustic neuromas were evaluated by comparing tumor size, ABR results, acoustic reflex findings and hearing loss. Size of tumor was obtained from the operative report based on visual observation by the surgeon.

Our preliminary findings indicate there is a poor correlation between tumor size and magnitude of pure tone hearing loss, except that smaller tumors tend to produce minimal hearing loss and larger tumors can present a range of normal to severe hearing loss. The relationship between abnormal acoustic reflex findings at 500 & 1000 Hz and the larger tumors is apparent. The more recent data by Coleman & House has shown that smaller acoustic neuromas tend to manifest abnormalities at 2000 or 4000 Hz using revised and more sensitive test criteria. ABR results also indicate a progression of abnormal effects on interaural IT5 differences as the lesion expands in size.

Our initial conclusions demonstrate that there is the potential for continuous reduction in hearing threshold, typically from the higher frequencies toward the lower frequencies, but a poor overall correlation between hearing loss and acoustic neuroma size. Good correlations exist between lesion size and ABR and acoustic reflex data. It is also apparent that the physiological factors that occur with tumor expansion create responses that appear similar in their degradation of hearing, ABR, and acoustic reflex measure. Our data further indicates that these tests evaluate functions which operate independent of each other.

THE DIFFERENTIAL EFFECT OF BARBITURATES ON AUDITORY BRAINSTEM VS. MIDDLE-LATENCY EVOKED RESPONSES: A CLINICAL STUDY

James W. Hall III, Steven J. Allen and Judy Hargadine
University of Texas Medical School
Houston, TX

High-dose barbiturates, including induced coma, are employed therapeutically in the management of increased intracranial pressure and to reduce the deleterious effects of cerebral ischemia secondary to vascular occlusion (eg., Brannarelli and Langfitt, 1978; Lawner and Simeone, 1978; Marshall and Shapiro, 1977). In deep barbiturate coma, however, clinical neurologic signs of CNS status (brainstem reflexes and motor responses) are no longer present and electroencephalogram (EEG) is isoelectric. The physician then, has virtually no means of assessing neurologic integrity in these acute brain-damaged patients.

In a recent experimental study, Sutton, et al (1982) found that high-dose barbiturates, adequate to induce coma, produced pronounced changes in the visual and long-latency somatosensory evoked responses, but had little effect on brainstem somatosensory and auditory evoked responses. There are, to date, no published clinical studies of the ABR in barbiturate coma. Nor has the influence of barbiturates on auditory brainstem vs. middle-latency response (AMR) been compared.

Serial measurements of the ABR and AMR were made for patients with acute, severe head-injury (a total of over 50 sessions) using commercially-available instrumentation. Most evaluations were done at bedside in an intensive care unit. Barbiturate blood levels and pertinent physiologic parameters (eg., body temperature, intracranial pressure, PaCO₂) were documented for each patient. Whenever possible, prebarbiturate baseline evoked response recordings were obtained, and then serial measurements were carried out regularly until the patient was completely withdrawn from barbiturates, as indicated by blood level Barbiturates did not differentially influence the ABR vs. AMR. Consistent with previous experimental results (eg., Bobbin, May, Lemoine, 1979; Sutton, et al, 1982), we found the ABR extremely resistant to therapeutic doses of barbiturates, although at very high blood levels (in excess of 40 ug/ml) latency changes of later wave components were sometimes observed. The ABR was reliably recorded in patients demonstrating no neurologic signs of CNS function. The AMR (Wave Pa) in contrast, was quite sensitive to barbiturate influence, and remained grossly depressed in amplitude even at blood levels of less than 10 ug/ml (toxic level). The Na component of the AMR appeared to be less influenced by barbiturates, but not as resistant as the ABR.

In addition to providing clinical confirmation of previous experimental studies of evoked responses in barbiturate coma, these data suggest a basic distinction in the neuro-anatomical and neuro-physiologic substrate of the auditory evoked responses. This final point is discussed in detail.

THE RESULTS OF THREE DICHOTIC SPEECH TESTS ON SUBJECTS WITH BRAINSTEM AND HEMISPHERIC LESIONS

Frank E. Musiek and Lisa M. Rackliffe
Dartmouth Medical School
Hanover, New Hampshire

The purpose of this study was to analyze the results of three audiological tests of dichotic listening which, to the author's knowledge, had not previously been compared. The Competing Sentences (Willeford, 1977), Staggered Spondaic Words (Katz, 1962) and a modified Dichotic Digits Test were used to test thirty subjects possessing a variety of surgically and/or neurologically diagnosed intracranial lesions (11 brainstem and 18 hemispheric). This group of subjects exhibited mean pure tone thresholds and speech discrimination scores which were essentially normal bilaterally. Normal performance on these dichotic tests was pre-determined to be approximately 90% or better for each ear on each test, a level 2 standard deviations below the mean for normal. The results of the tests were then analyzed according to the number of individual subjects who yielded abnormal results in at least one ear. In addition, analysis of laterality effects among the three tests were carried out.

The results of the individual subjects exhibiting abnormal scores revealed that the Dichotic Digit Test was most sensitive, followed closely by the SSW and then Competing Sentences in detecting both hemispheric and brainstem lesions. Further, all three tests appeared more sensitive to hemispheric lesions than brainstem disorders.

The mean laterality effects for those subjects with hemispheric lesions limited to one side indicated that significantly greater deficits were found for the ear contralateral to the side of the hemispheric lesion. This trend was similar for all three dichotic tests. In addition, brainstem lesions limited to one side demonstrated greater ipsilateral than contralateral deficits.

In conclusion, these dichotic listening tests all exhibited

greater sensitivity to hemispheric than brainstem lesions, with the Dichotic Digit Test being the most sensitive, and the Competing Sentence Test being least sensitive to both types of lesions. Further, subjects with brainstem lesions exhibited greater ipsilateral deficits on all three tests, while those with hemispheric lesions showed greater contralateral deficits. These analyses as well as others are further discussed in this study.

INTERPRETING CENTRAL AUDITORY-LANGUAGE PROCESSING TEST RESULTS IN CHILDREN

Jay R. Lucker

Private Practice in Audiology & Rehabilitation
Scarsdale & Ossining, N.Y.

The ability to evaluate central auditory-language processing skills in children has been established. Audiologists are taught administration and scoring for various central auditory tests, however, interpreting test results and providing useful information for remediation is often lacking. It is felt that the problem lies in the application of an inappropriate model of central auditory-language processing in children. The purpose of this paper is to discuss various models of central auditory functioning applied with children, and develop an understanding of a more appropriate model.

The first model considered is called the PASS/FAIL model. According to this model, children are administered central auditory tests, and if they fail, they are diagnosed as having a central auditory impairment requiring remediation on those listening skills they failed on the tests or a general program of improving listening is developed which is unrelated to specific needs. This model is felt to be inappropriate for evaluating and remediating central auditory-language processing in children.

The second model is founded upon research with adults and lesion studies. This model presumes a "site-of-lesion" or region of dysfunctioning causing the breakdown in central auditory functioning. According to this model, children's poor performance on central auditory tests are described in terms of specific focus of central auditory nervous system dysfunctioning and remediation becomes unrelated to the diagnosed problem. Again, remediation may be to improve the skills the child performed poorly on during the testing or to generally improve listening abilities. This model is felt to be inappropriate and may even be invalid until a specific relationship is proven between central auditory-language processing and "site-of-dysfunctioning" in children.

The last model discussed is one developed by the author. It integrates knowledge from neurophysiology and neuropsychology with knowledge from cognitive psychology and language. This model will be discussed in depth. It views specific process (such as: focusing, filtering, selective focusing, integrating, feedback, feedforward, decision making, etc.) and relates these cognitive/linguistic processes to success or failure to perform on specific central auditory-language processing tasks. This model also views central auditory evaluation as a method for determining why children are having difficulties learning and not as a method for identifying central with processing problems. It will further be demonstrated how application of this model to central auditory evaluation yields appropriate remediation programming to develop strategies to overcome general processing deficits.

NEUROPHYSIOLOGICAL CORRELATES OF SPECIFIC LEARNING DISABILITIES

Steven Staller

Denver Ear Institute
Denver, Colorado

Identification of physiological correlates of specific perceptual, processing and cognitive deficits would greatly strengthen the ability to isolate homogenous subgroups of children with learning disabilities. Theoretically, the differentiation of children with learned behavioral deficits, may allow more effective design and implementation of remediation protocols in this population.

To date, studies of physiological measures in this population have been equivocal due to: 1) The lack of adequate multi-dimensional selection criteria for the target population. 2) The use of physiological measures which have not been sensitive to subtle deficits associated with the learning disabled population. and 3) The use of very small experimental samples.

In an attempt to address these concerns, an experimental group of 30 learning disabled children were evaluated with a comprehensive battery of physiological measures, central auditory processing tests and speech discrimination in noise. These children were drawn from a pool of 100 potential candidates who were failing in the regular classroom but had a performance of verbal IQ (WISC-R) within the normal range. The experimental group was selected based selected tests of perceptual function, speech & language reception and expression as well as auditory and visual processing.

The physiological battery included: 1) The Binaural Inter-

action of the ABR. 2) The P300 Cortical Evoked Potential to auditory tonal stimuli and pattern visual stimuli. 3) Sinusoidal Harmonic Acceleration Vestibular evaluation. 4) The Middle Latency AER (MLR). and 5) Smooth Pursuit Oculomotor Tracking.

Data obtained from this group was compared with an age and S.E.S. matched control group from the same school district. Significant differences were noted between the two groups and will be discussed. The most consistently abnormal finding noted in the experimental group was vestibular dysfunction. Correlations between behavioral and physiological measures which theoretically involve the same system, task or modality will also be briefly discussed.

USE OF NU-6 WORD LISTS IN ROLLOVER MEASUREMENT

Dianne H. Meyer and E. Tracy Mishler

University of Ill. Eye and Ear Infirmary
Chicago, Illinois

Measurement of PI-PB function is a special auditory test used in the differentiation of cochlear from retrocochlear hearing loss. Jerger and Jerger (1971) and Dirks et al. (1977) tested subjects with 1/2 lists (25 words) of the PAL-50 word lists and found that a "rollover" index of .45 identified retrocochlear pathology. In contrast, Bess et al. (1979) used 1/2 lists of the NU-6 word lists and found that a rollover index of .25 was associated with retrocochlear disorders. The discrepancy found among these studies in the critical rollover index may be due to differences in PB materials, to differences among the populations studied, or to the variability inherent in using 1/2-lists for speech discrimination testing. The purpose of this study was to account for discrimination score variability in determining a critical rollover index that is appropriate for use with NU-6 word lists.

PI-PB functions were obtained on normal, cochlea-impaired, and radiographically or surgically confirmed retrocochlear subjects. Tape recorded NU-6 lists (Auditec of St. Louis) were delivered at three to five suprathreshold levels, depending upon the severity of the loss. Full 50-word lists were used because of the reduced reliability and greater score variability found when only 1/2-lists are used (Jirsa et al., 1975; Thornton and Raffin, 1978). A rollover index was computed for each subject, according to the formula recommended by Jerger and Jerger (1971).

The results of this study will be discussed relevant to (a) the relationship between degree of loss and PB max; (b) the effect of discrimination score variability in determining the rollover index; and (c) the rollover index for NU-6 lists that best distinguishes between cochlear and retrocochlear subjects.

THE NATURAL HISTORY OF SUPRA-HIGH FREQUENCY HEARING IN CHILDREN 8-18 YEARS OF AGE

Marion P. Downs, John Fletcher, John Lampe,
Mildred Doster, Jane Simontron

Five hundred third-grade school children from representative socio-economic groups were selected for a 10-year study of the Natural History of High Frequency Hearing, 4000-18,000 Hz. Using a Rudmose Manual Audiometer these children were given threshold tests each year for ten years. At the end of the study those remaining were queried as to their noise exposure, disease history (including otitis media) and other factors that might effect high frequency hearing.

The results of this study demonstrate age-related normative data for the supra-high frequencies of children 8-18 years old. In addition the effect of noise exposure and disease on the children's hearing of those frequencies are shown. The study supplements the 1972 report (Northern et al.) of adult age-related norms of supra high frequency hearing.

RETROSPECTIVE STUDY OF THE ETIOLOGY OF HEARING LOSS IN CHILDREN

Hiroshi Shimizu and M. Cara Erskine

Johns Hopkins School of Medicine
Baltimore, Maryland

Knowing the cause of hearing impairment is essential for both its prevention and early detection. Establishment of an effective high risk registry for hearing impairment solely depends on extensive epidemiologic studies of the etiology. The eradication of hearing impairments cannot be achieved without identification of the causes. Otolaryngologists and pediatricians as well as clinical audiologists must be fully informed as to the etiology of hearing impairment as they are most likely to be the first professionals to encounter patients with a possible hearing impairment.

It is probable that medical advancement will continuously alter the statistics of the etiological pattern. Wide spread vaccination, improved prenatal, natal and neonatal care, prompt administration of Rh globulin, development of antibiotics, preventive abortion and decreased birth rate seem to have reduced certain types of hearing impairment and

changed etiologic patterns.

The etiology of hearing impairment has been discussed by many investigators elsewhere, but percent distribution of reported causes presents wide diversity between various reports. For example, the incidence of genetic hearing impairment ranges from 7.6% to 51.5%. The disagreement perhaps stems from the difference in the size and nature of the study population and methodology. There have been few studies on a large population.

In order to investigate the incidence of various causative factors of hearing impairment in a large general pediatric population and changes in the etiologic pattern over a period of 16 years, we have reviewed the records of patients younger than 18 years of age who were referred to the Hearing and Speech Clinic of The Johns Hopkins Hospital from 1965 through 1980. The patients of the Clinic are not restricted to any particular population. They were all referred for an initial audiologic evaluation.

The total number of records was 6,577. A hearing loss was ruled out in 1,808 patients. In 182 patients, no confirmed information was available about the presence or absence of hearing impairment or the nature of the hearing loss due to lack of the follow-up evaluation. Consequently, these 182 cases were excluded from the study. The remaining 4,633 cases were carefully reviewed to identify the proximate cause of hearing impairment. In some instances the patient had a history of two or more possible etiologies. If the available information gave no clue whatsoever as to which one of these causative factors was the most probably etiology, the case was unidentified, undetermined, and no information. Nearly one-third of the causes (30.1%) belonged to this group.

The total etiologic factors were divided into genetic, and non-genetic prenatal, perinatal and postnatal causes. Thirty-five causative factors were identified and their percent distribution will be reported.

The rate of the genetic cases was 7.4% of the total population, which agreed with the report by the national census of the deaf population of 1971. The low ratio of the genetic cases is obviously ascribed to the fact that the data includes not only prelinguistic hearing impairment but also a large number of otitis media, all other conceivable causes of late on-set. Interestingly, however, the data shows a relative increase in the incidence or identification of genetic cases in the later years. The genetic cases were the highest in frequency among the prelinguistic hearing loss.

Incidence figures of the prenatal, perinatal and postnatal etiologic factors were etiologic factors were 8.7%, 6.1% and 47.5% respectively. The data showed an unusually high incidence of prenatal rubella for the well known reason that the United States experienced the worst rubella epidemic from 1963 to 1965. Among the perinatal causative factors, premature birth showed the largest incidence. It is significant to note that 47.5% of the cases of premature birth with confirmed hearing impairment weighed more than 1,500 grams.

One-third of the total population (36.5%) had a hearing loss secondary to middle ear problems. The ratio between suppurative otitis media and serous otitis media was approximately one to two. The incidence of otitis media was followed by postnatal viral or bacterial infection, in which meningitis had the highest incidence, and in decreasing frequency by temporal bone fractures, trauma to the middle ear, pseudohypacusis, acoustic trauma, ototoxic drugs, unexplained high febrile illness, neoplasms and hypoxia.

The incidence of causative factors by the year of the birth clearly showed a gradual decrease in hearing impairment due to maternal rubella, reflecting the advancement of its prevention. It was reduced to zero percent in children who were born after 1973. Contrary to what has been expected, no dramatic change in the number of hearing impairment due to hyperbilirubinemia was observed throughout the years included in this investigation.

Statistical data on the nature and degree of hearing loss secondary to selected etiologic factors will be presented. We intend to include the data obtained from the patients seen in 1981 and 1982.

RESPONSES OF NEWBORNS TO HIGH PASS FILTERED NOISES

Sanford E. Gerber and Mark S. Dobkin

Speech and Hearing Center
University of California
Santa Barbara, CA

Over quite a number of years clinicians and researchers alike have employed a vast array of acoustic events supposing that these phenomena would elicit motor responses of neonates if they were loud enough. As a result, we have employed noise making toys, frequently modulated tones, narrow band noises, wide band noises, white noise, sine waves, coin clicks, watch ticks, speech, whispered speech, and anything else which might have been handy. Many of these investigations have failed to ask which signals are, in

fact, stimuli. In other words, what serves as an auditory stimulus for an infant?

Following the advice of the Nova Scotia Conference on Early Identification of Hearing Loss to use high pass filtered noise, this study centered on the cut-off frequency. While the Nova Scotia conference (Mencher, 1976) recommended a noise which is filtered below 750 Hz, and this signal has been shown to be more effective than a narrow band noise (Gerber and Mencher, 1979), until now no one has investigated the effect of the cut-off frequency. This question is important for two reasons: we still need to find an optimum signal for screening of infants, and we need to determine the properties of stimulus complexity as a function of frequency spectra. Hence, we employed three different cut-off frequencies of high pass filtered noise - 500, 1000, and 2000 Hz - and presented them in random sequence to a number of full-term, well newborns. Following the procedures we have used repeatedly (e.g., Gerber and Mencher, 1979; Gerber, 1983) each infant was presented with eight repetitions of each signal. Given that there were three spectra in this study, there were 24 signal presentations. Furthermore, the 24 events were recorded in random sequence and the levels adjusted so that all were at 90 dBA.

Eighteen infants participated in this study. The results indicated that signal complexity as represented by bandwidth constitutes the best stimulus. That is, the wider the band, the more often the infant will respond. Of course, this finding is confounded by the fact that the wider the band, the more low frequency content there is. In other words, while infants seem to be more responsive to wider bands, they are also more responsive to lower frequencies. Consequently, it may indeed be the case that the "Nova Scotia spectrum" is the most clinically useful because of its inclusion of low, but not too low, frequencies.

CRIB-O-GRAM AND AUDITORY BRAINSTEM RESPONSE: DIRECT COMPARISON OF TWO INFANT HEARING SCREENING METHODS

Anne L. Kuklinski, and Holly Hosford-Dunn
Stanford Audiology Clinic, Division of Otolaryngology
Stanford University Medical Center
Stanford, CA

Crib-O-Gram (COG) and Auditory Brainstem Response (ABR) data were collected in a local Neonatal Intensive Care Unit (NICU) and scored without knowledge of follow-up. Of 747 infants tested by COG, 162 (21.7%) failed (scalar score - 50.5), in fairly good agreement with the 17-19% rates Marcellino (1982) reported for two groups in NICU. COG failures and every fifth pass were screened by ABR, with ABR passes defined as wave V presence/replication at 30 dB nHL in either ear.

Data on 69 infants have been scored (Table 1). Numerous subjects were discarded because of ABR technical problems/incomplete testing. Additional data remains to be judged. Forty six infants failed COG. Assuming the average failure rate of 21.7%, this subgroup was drawn from an estimated sample population of 219. Using the 11.7% incidence of hearing loss reported in COG failures (Marcellino, 1979), we predict 5.38 babies to have significant hearing loss.

ABR failed 36, yielding an estimated failure rate of 16.4%, in agreement with Galambos et al's (1982) rate of 15.84%. Using the 13% incidence of significant hearing loss he reported at follow-up of ABR screening failures, we predict serious impairment in 3.94 subjects.

Chi square testing showed no significant interaction in the screening distributions. These data contrast with Marcellino's finding of no COG-Pass/ABR-Fail occurrences. Since ours and other reports show high false positive rates for both methods, it seems inappropriate to establish false positive and negative rates by comparing one method against the "standard" of the other. The two methods test different components of auditory performance: ABR measures cochlear sensitivity, COG measures behavioral responses to suprathreshold stimuli. A baby could fail COG yet pass ABR if he were: 1) out of crib or poorly placed on sensor; 2) in deep sleep; 3) suffering cortical damage. A COG-Pass and ABR-Fail could result due to: 1) poor reliability due to equipment or infant noise; 2) poor tester technique; 3) transient hearing loss resulting from a real or artificial conductive component.

Analysis of audiometric follow-up data and enlarging sample group will allow comparisons of sensitivity and specificity of both methods. Results of such comparisons will be discussed in the presentation.

A DESCRIPTION OF THE RESULTS OF THE PAST FIVE YEARS OF A HIGH RISK HEARING SCREENING PROGRAM

Wynette J. Moneka and Karen M. Gollegly
Northwestern University Medical School
Chicago, Illinois

The use of a high risk register for targeting those infants at risk for hearing loss is a well-accepted procedure since the Supplementary Statement of the Joint Committee (1974). However, the lack of further guidelines from this group be-

tween 1974 and the Position Statement (1982), left the audiologic and pediatric/medical community without periodic updating. During the longitudinal Crib-O-Gram project, Simmons (1979, 1980), compiled detailed information on the realities composing high-risk status for hearing loss in contemporary neonatology. However, those programs not in the field trials for the Crib-O-Gram study, were left to decide whether to test high risk infants or not and if so, how to test. In 1976, the Nova Scotia Conference, though not an "official" body, did resolve that the use of behavioral screening programs was acceptable, thus clearing the way for programs to test infants in addition to identifying them as at risk for hearing loss.

Following the Nova Scotia Conference, Prentice Women's Hospital and Maternity Center and Northwestern University, Medical Center Hearing Services, established a program for the systematic identification, screening and follow-up of high risk infants. A chart of the organization of the program, Figure 1, shows the initial screening step plus two routine follow-up visits for the most at-risk infants who are slated for periodic re-evaluation by the entire team of professionals. Thus far, 1061 babies have been tested between January, 1977, and December, 1982. While the initial test failure rates were higher, the overall failure rate is only 8% (Figure 2), a reasonable number which also compares quite well with other methods. It is extremely important to note that the rate of identification of hearing impairment from the nursery phase of our program is 1:55. This figure is quite close to the lower level of the stated 2-5% incidence figures provided by the 1982 Position Statement. If only the later years of the program are considered, identification rates are at least 2%, Figure 2.

This presentation would detail the program we have established, and the findings thus far. As noted above, we feel that a carefully applied behavioral program can prove successful. The risk factors present in the identified cases of hearing loss will be classified as we have some concerns about the items slated in the Position Statement. A category that we have established called Priority Risk, will be discussed as it has helped us in conceptualizing a special category of cases for more aggressive followup. Examples of such cases are shown in Figure 3. At the present time, we are in the process of acquiring normative data on a portable auditory brainstem response unit (ABR/BSER) which the University received. While we have had a stationary test unit to use for suspected cases of hearing loss, our plans to incorporate this unit into the present program will also be shared.

PERFORMANCE CHARACTERISTICS OF HEARING AID COMPATIBLE AND INCOMPATIBLE TELEPHONE RECEIVERS

Vic S. Gladstone and Eileen Kahl
Baltimore, MD

Hearing aid-telephone incompatibility has been a concern since the mid 1960's when AT&T and its affiliates began installing incompatible receivers in its telephone sets (Gladstone, 1975). Since that time, efforts by consumer groups have succeeded in reversing AT&T's intent to have all coin-operated phones contain incompatible receivers. By 1980, over 95% of coin-operated telephones were hearing aid compatible (OUT, Archives, 1980).

A persistent concern has been the resistance/reluctance of AT & T, its affiliates, and the many non-Bell telephone companies to provide hearing aid compatible receivers in all telephones such as business, private-system, and designer-type models. An alternative to complete change-over offered by AT & T has been an adapter which converts acoustic energy to electromagnetic energy thus enabling use of a hearing aid with telephone pick up coil. Objections raised to the adapter have included cost, size, conspicuousness, and, perhaps most important, poor acoustic quality (OUT, Archives, 1980). This study was conducted to examine the performance characteristics of a hearing aid compatible receiver (WE-U1) and an incompatible receiver (WE-TRIMLINE) requiring an adapter (WE-100A).

Three experiments were undertaken to evaluate the psychoacoustic, electroacoustic, and electromagnetically for both receivers; (1) individually, and (2) coupled to each of three hearing aids. Each hearing aid was evaluated according to ANSI S3.22-1976 Specifications of Hearing Aid Characteristics and found to meet such specifications.

The hearing aid volume control was set to the reference test gain position which represents the "in-use" position. The hearing aid output was fed to the measuring amplifier section of a Bruel and Kjaer (B&K) Type 2010 Heterodyne Analyzer, the output of which was coupled to a B&K 2307 Laboratory Graphic Level Recorder (GLR). The GLR controlled the frequency sweep of the Beat Frequency Oscillator (BFO) section of the 2010 Heterodyne Analyzer. The BFO served as the input signal source to the telephone receivers.

The input signal was a pure tone adjusted to 250 millivolts (mV) at 1000 Hz as monitored at the receiver terminals by a Tektronix 7313 dual trace storage oscilloscope. Electromagnetic coupling was effected by comparing the hearing aid output displayed on one channel of the oscilloscope to the input

signal to the telephone receiver displayed on the second channel of the oscilloscope. The hearing aid was oriented relative to the receiver to achieve a maximum signal display while preserving wave form quality. In the case of the WE-TRIMLINE receiver the electromagnetic coupling was accomplished via the WE-100A adapter. The input signal was then swept over the frequency range from 100 Hz to 7000 Hz with the frequency response automatically recorded by the GLR. Total Harmonic distortion was measured at 1000 Hz at the same 250 mV at 1000 Hz input signal via the B&K Heterodyne Slave Filter 2020. Signal-to-noise ratio at 1000 Hz was measured by obtaining a reading from the 2010 measuring amplifier with a 250 mV at 1000 Hz signal into the receiver and then obtaining another reading with the input signal removed.

Results from experiments 1 and 2 reveal that the performance characteristics were superior for the hearing aid compatible WE-U1 receiver than for the WE-TRIMLINE (an incompatible receiver, when required). Psychoacoustic measures were obtained by evaluating the speech discrimination ability of normal listeners to material recorded via the electroacoustically and electromagnetically coupled hearing aids and both telephone receivers. Results and implications for clinical management of hearing aid wearers, future research, and telephone-hearing aid compatibility will be discussed.

A CLINICALLY MANUFACTURED STEPPED-DIAMETER EARMOLD FOR SUPERIOR AIDED LISTENING

Michael Valente
Omaha, Nebraska

Killion (1981) introduced a series of damped stepped diameter earmold configurations for improved speech intelligibility when utilized with hearing aids having wideband receivers. Several studies (Rezen, 1980; Mueller, Schwartz, and Sung, 1981; Sung and Sung, 1982) have reported superior performance with the stepped diameter earmold configuration when compared to a traditional earmold configuration (i.e., #13 tubing from the tip of the earhook to the tip of the earmold without the use of damping). Recently, many of the Killion earmold designs have become commercially available (i.e., 6R10, 6R12 and 8CR). However, their costs are relatively expensive (\$11.50 to \$25.00 per earmold) and additional cost is incurred by requiring the patient to return for the hearing aid evaluation. A method has been established to prepare a damped stepped diameter earmold (8CR) cost of which is rather inexpensive (less than \$2.00) and which may be prepared without the need for a second visit. This paper will describe the design of the earmold as well as its psychophysical performance in comparison to a traditional custom earmold.

Twenty-two veterans (it is anticipated that the number of subjects will be approximately forty by the time of our convention) have been included in this study. All subjects had sensorineural hearing loss which varied in magnitude and configuration. For each subject, two earmolds were prepared. The first earmold was custom made occluding the traditional earmold ordered from an earmold laboratory. This earmold consisted of #13 tubing extended to the tip of the earhook. When coupled to the hearing aid, this earmold design did not incorporate the use of damping. The second earmold was the experimental earmold which closely adhered to the dimensions specified by Killion for his 8CR design. The earmold consisted of three sections of tubing. The first section (most medial) consisted of fourteen millimeters of #7 tubing (I.D. equals 4.0 millimeters). The second section consisted of twenty-two millimeters of #9 tubing (I.D. equals 3.0 millimeters) where the first three millimeters were bonded to the #7 tubing. The last section consisted of #13 tubing (I.D. equals 1.93 millimeters) in which the first three millimeters were bonded into the #9 tubing. The length of this last section varied depending upon the individual's ear configuration. In this experimental earmold a 1500 ohm fused mesh damper was placed at the tip of the earhook. This earmold was coupled to the subjects ear canal utilizing a pre-drilled soft ear insert which varied in diameter (sizes 2 - 6) depending upon the diameter of the subject's ear canal.

Each of the two earmolds were evaluated psychophysically in determining unaided and aided (functional gain) spondee words as well as warble tones (5%) between 250-6000 Hz. Also evaluated were word discrimination scores (recorded versions of CID W-22) in quiet and noise (multi-talker background at a +6 S/N ratio). All procedures were evaluated under conditions of near-ear listening.

Results revealed:

1. Functional gain was significantly better with the stepped diameter earmold at 2000-6000 Hz.
2. There were no significant differences between the two earmold designs in functional gain for spondee words or warble tones at 250-1000 Hz.
3. Word discrimination scores were significantly better in quiet and noise for the 8CR design.
4. Considerable variability was revealed for both earmold designs.

TEST-RE-TEST RELIABILITY OF THE HEARING HANDICAP INVENTORY FOR THE ELDERLY

Barbara E. Weinstein, Ira M. Ventry, Jaclyn B. Spitzer

The Hearing Handicap Inventory for the Elderly (HHIE) is a new self-assessment technique designed to quantify the emotional and social effects of hearing impairment in the non-institutionalized elderly. The HHIE is comprised of 25 items and is divided into two subscales: a 13 item emotional subscale which explores emotional consequences of hearing impairment and a 12 item social/situational subscale which explores both social and situational effects. The internal consistency of the total scale and its two subscales is quite high (.88 to .95), as is its split-half reliability (.94).

In view of the high internal consistency of the HHIE, it is gaining widespread appeal for its clinical utility with the elderly. For example, the scale has been used in large-scale hearing screening programs, to pinpoint social/situational problems associated with hearing impairment and to serve as the basis for counseling the elderly. However, its application as a measure of change in self-perceived hearing handicap (as such change may be derived from audiologic intervention) has been limited. The latter application has not been advocated due to the absence of test-re-test reliability data.

The purpose of the current paper is to present test-re-test reliability data on the total HHIE scales and on its subscales. In addition, test-re-test reliability as a function of degree of hearing impairment will also be discussed. Finally, the reliability of a paper-pencil vs. face-to-face administration of the HHIE will also be discussed. The clinical application of these findings (eg. methodological issues) will be addressed.

The test-re-test reliability of the (HHIE) was assessed on a sample of 40 non-institutionalized individuals over the age of 65 with sensorineural hearing loss. The test-re-test reliability of the HHIE using a face-to-face administration method was .96, while test-re-test reliability of paper-pencil administration was .84. Test-re-test reliability of the subscales is currently under analysis, as is reliability as a function of hearing level category.

AN ARTICULATION INDEX STUDY OF PHONEMIC REGRESSION IN THE ELDERLY

Chaslav V. Pavlovich and Robert McCroskey

Department of Communicative Disorders

University of Mississippi and Wichita State University

The concept of Phonemic Regression (disproportionately poorer understanding of speech than would be expected on the basis of a listener's threshold of auditory sensitivity) has been widely accepted for older individuals, in spite of the fact that the phenomenon has received only limited research attention, and the fact that the effects of Phonemic Regression are not as documented or as understood as its associated deficit in hearing sensitivity.

The contribution of this investigation lies in the application of an Articulation Index procedure to the accounting for the reduction in speech intelligibility due to the loss in threshold sensitivity alone. There appeared to be a need to assess and compare the severity of Phonemic Regression for low frequencies, where threshold sensitivity is relatively good, with the severity of Phonemic Regression in the higher frequencies where threshold sensitivity loss is usually greater. Further, there was an attempt to relate the temporal resolving power of the aging auditory system to performance in the lower and in the higher frequency ranges.

The purpose was to explore, by means of an Articulation Index (AI) procedure, whether the Phonemic Regression phenomenon is: 1) present in old age; 2) whether it is frequency specific; and 3) whether it is accompanied by a deterioration in the temporal processing abilities of this older population. There were 28 subjects equally divided according to age. The mean age of the younger group was 18 years and the mean age of the older group was 67 years. The subjects from the older age groups had a mild to moderate hearing loss for higher frequencies (above 1400Hz) and normal hearing (better than 15dB HL) for lower frequencies (below 1400Hz). The subjects from the younger age group had normal hearing. Each subject's speech discrimination ability was tested using high passed (1400Hz cutoff frequency) and low passed (1400Hz cutoff frequency) filtered PB words (PAL PB-50 material). Their temporal processing abilities were measured at 500Hz and 4000Hz in terms of the ability of the auditory system to detect silent intervals between tone clicks.

The main research tool of the study was the AI theory which can predict, from the proportion of the speech spectrum that is audible within the residual hearing area, the speech discrimination of listeners — provided no suprathreshold deficits of the auditory system are present. However, since the presence or absence of such deficits was the object of this investigation, a variable termed "regression proficiency factor" was introduced in the AI formulas to represent such phenomena (phonemic regression). The mean values of this variable in the low frequencies (below 1400Hz) and in the high frequencies

(Cont. on pg. 8)

Also, implications of these results will be discussed in terms of the durability of the experimental earmold as well as illustrating those patients for which this earmold may not be appropriate. Finally, a section will be included concerning the usefulness of the stepped diameter earmold with hearing aids not possessing wideband receivers.

AUDITORY ELECTRICAL STIMULATION: EFFECTS OF TINNITUS

Brady J. Edgerton, John T. McElveen
and Judith A. Brimacombe
House Ear Institute
Los Angeles, California

At least 80% of the patients seen for otologic problems manifest some degree of tinnitus. Unfortunately, the physiologic mechanisms underlying tinnitus are not known. Many diverse treatment methods have been reported to be successful for some tinnitus patients; no procedure is successful in all cases. The severe to profoundly hearing-impaired patient frequently fails to respond to conventional treatment forms such as hearing aids, biofeedback, tinnitus maskers, or drugs; electrical stimulation, however, has been reported to be successful in many of these cases.

An analysis of the effectiveness of the House cochlear implant (CI) for tinnitus suppression revealed that significant tinnitus reduction has occurred in 50% of the patients (Total N = 68), no change occurred for 45%, and 5% reported an increase in tinnitus. The CI data suggest that patients who are implanted primarily to restore hearing, may reflect a slightly higher degree of successful tinnitus suppression than patients who receive the CI specifically for tinnitus relief. The number of patients in this latter category, however, is extremely small and therefore requires additional investigation before any conclusive statements can be made.

Further investigation into the effects of electrical stimulation on tinnitus is currently being done in a series of acute electrical stimulation experiments. Patients include those with debilitating tinnitus who have not responded to conventional therapies and patients with severe tinnitus that are undergoing stapedectomy surgery. Stimulation is done at the round window using sinusoids, monophasic and biphasic pulses, and direct currents. Preliminary findings indicate that these patients' responses to electrical stimuli are variable. No single factor or group of factors has been predictive of the degree of tinnitus suppression during electrical stimulation. Often, electrical stimulation has not suppressed tinnitus in patients for whom suppression was expected. Further investigation is necessary to determine the viability of electrical stimulation for severe tinnitus sufferers.

TINNITUS EVALUATION AND TREATMENT

Robert Johnson, Jack Vernon
Mary Meikle, and Robert Brummett
Department of Otolaryngology
Kresge Hearing Research Laboratory
Portland, Oregon

During the past decade, considerable interest has been generated in the area of tinnitus both in the United States and in selected foreign countries. This interest has resulted in various improvements of both evaluation and treatment procedures.

To date, approximately 2500 tinnitus patients have been seen at the Kresge Hearing Research Laboratory in Portland, Oregon and a series of experiments have addressed the problems associated with this symptom. Investigations have dealt with methods for both evaluating and treating tinnitus patients and this information has been entered into a large data registry. This information has accumulated from patients seen at the Tinnitus Clinic during the past seven years and in the Department of Nephrology and Rheumatology for three years. Treatment procedures have included medical treatment, tinnitus masking and drug therapy.

Quantitative data include information regarding audiological assessments, tinnitus evaluations and related medical problems associated with this symptom. These data will be reported and discussed and findings of specific projects will be highlighted. Current problems involved in evaluating and treating tinnitus patients will be reported as will future directions for research in the next decade.

SUMMARY

Information from approximately 2500 tinnitus patients accumulated at the Kresge Hearing Research Laboratory in Portland, Oregon which has been analyzed and entered into a large data registry will be reported and discussed. Various research projects completed during the past three years involving both the evaluation and treatment of tinnitus will be highlighted.

PILOT STUDY ON THE EFFECTS OF A GROUP INTERVENTION ON NORMAL-HEARING SUBJECTS SUFFERING FROM HANDICAPPING TINNITUS

Normandin, N.; Roberge, C.; Bergeron, L.

A pilot study was undertaken to measure the effects of group intervention on ten normal-hearing subjects of 30 to 50 years

old suffering from handicapping tinnitus since at least one year and having no hope for treatment in a near future.

A palliative approach was developed to reduce handicap which was operationally defined as an increase in tolerance of tinnitus and maintenance or reintegration in familial, social and professional life.

Based on review of literature, clinical experience and formulation of needs and expectations from the individuals themselves (at a preliminary meeting), the group intervention provided two types of services. First, general information was transmitted concerning the auditory system, the etiology and treatment of tinnitus, and the psychophysiological effects of stress on the individual; second, basic practicum on general relaxation was done and regular practice at home was encouraged.

Measurements of before - after of knowledge, attitudes and behaviors was performed by means of specifically developed questionnaires on handicap, case history, degree of stress and anxiety, and adjustment to changes of life. Preliminary results are presented in terms of percentages of responses after intervention.

Findings suggest that explanation of the problems to the individuals, paired with group gathering, identification of life stressful events, and basic training on general relaxation provided better tolerance to tinnitus problem, reduced feeling of helplessness and encouraged behavior of self-control. It was also obvious that the subjects who had consulted regular clinics did not have any knowledge about the diverse aspects related to their problem.

Results are discussed in terms of clinical application and further researches. Group intervention can become a very important adjunct to traditional individual case-by-case intervention in cases seeking palliatives to non-treatment tinnitus.

OPTIONS FOR THE PROFOUNDLY DEAF: AN OUTGROWTH OF THE COCHLEAR IMPLANT PROJECT

Molly L. Pope, Richard T. Myamoto, Jon K. Shallop,
Marjorie L. Kienle, Amy J. McConkey, Barbara Young

In 1979 a cochlear implant team was established at the Indiana University Medical Center. Since then, more than 150 patients have been evaluated as potential candidates for a cochlear implant. To date, 22 patients have received a House-Urbain single channel device.

Candidates for the cochlear implant receive an extensive evaluation and are selected for the implant procedure on the basis of medical, audiological and psychological criteria. The medical evaluation includes history and physical examination, electronystagmography and radiographic studies. Audiological testing is used to select subjects who are profoundly deaf. In addition, performance with a hearing aid is evaluated using speech and environmental sound discrimination tasks. Speechreading and voice production assessments are obtained. Prospective implant candidates are psychologically assessed through interviews, tests and questionnaires designed to measure cognitive, neuropsychological and personality functions.

Following this extensive work-up, the cochlear implant team makes recommendations regarding which device and rehabilitation strategy is most appropriate for the patient. Candidates who are not appropriate for the cochlear implant are then counseled regarding the alternatives available to them.

The purpose of this report is to review the status of those patients who consulted our team, but for whom an implant was not recommended. Some of our most gratifying results were seen in this heterogeneous group of patients. Many of these patients have been helped by alternate rehabilitation strategies. Depending on the level of residual auditory function, in many cases, traditional amplification fittings or amplification with minimal cue training has proven to be most appropriate. Vibro-tactile training has been utilized effectively in a few selected patients. This paper will discuss our rationale for recommending a particular device or rehabilitation program, based upon data obtained in the evaluation and upon our clinical experience with a large number of hearing impaired patients. Specific case information will also be presented.

The purpose of this report is to review the status of prospective cochlear implant patients, who consulted our implant team at Indiana University Medical School. The focus of the paper will be on those patients for whom an implant was not recommended. Some of our most gratifying results were seen in this heterogeneous group of hearing impaired patients. Many of these patients have been helped by alternative devices and rehabilitative strategies.

We will discuss the rationale for recommending a particular device and/or rehabilitative program in various clinical situations and give specific case examples.

Abstracts (cont. from pg. 7)

cies (above 1400Hz) were determined for the older age group using the observed filtered speech discrimination scores and threshold sensitivity values off all 28 subjects. These mean values were subsequently analyzed to determine whether or not they were different from unity, since unity represents the value of the regression proficiency factor if there is no phonemic regression.

The analysis of the results led to the following conclusions:

1) Phonemic regression phenomenon is present in the population represented by the group of older individuals who participated in this study.

2) The observed phonemic regression is frequency specific. It is not present in the low frequencies where the subjects had normal hearing but it is present in the high frequencies where they had mild to moderate hearing losses. A consequence of this is that the application of the AI theory in its present form to the prediction of speech discrimination by the hearing impaired is not possible, at least for the population represented by elderly individuals tested in this study. A revision of the procedure to account for suprathreshold distortion of speech is necessary.

3) The association between phonemic regression and the distortion in the temporal processing abilities was not evident.

Winter, 1984

Cordless Telephones Can Cause Permanent Hearing Loss

Several cases of documented permanent sensorineural hearing loss resulting from cordless telephones have recently come to the attention of the AAO-HNS.

According to the Federal Communications Commission (FCC), the agency which certifies this equipment, there may be three to five million cordless telephones in the U.S. The product came on the market two years ago, and now there are 30 to 40 basic models with 150 to 200 variations. Sales are expected to continue to rise rapidly (i.e. \$1 billion in sales is projected for the next two years).

Complaints filed with the federal government by Academy members and affected users have prompted an investigation through the Consumer Product Safety Commission, an independent federal regulatory agency.

The noise-induced hearing loss results from improper use of the equipment. The public is accustomed to the conventional "wired" telephone which automatically stops ringing when answered. Cordless telephones have a "flip switch" which is normally in a "standby" position and has to be moved manually to a "talk" position. If the user forgets to flip the switch, the ringing continues directly into his ear because (in all except one model) the audio signal device for incoming calls and the intercom or page is located in the ear piece.

The CPSC has logged numerous complaints of painful ringing and tinnitus. In some cases there was no apparent related hearing loss. Other cases indicated hearing loss of 20 to 25%.

There have also been reports of violent headache and disorientation. Painful sounds, including a pistol-like "crack" or loud pop, have also been reported. This may be some type of radio interference. These types of noises did not occur when the CPSC conducted laboratory tests on five models. Its tests found the sound level in a range of 123 to 135 dB.

The CPSC staff met with cordless telephone manufacturers. Warning literature and stickers have been discussed, and some companies have started using them. The CPSC staff has proposed a "consumer alert" which, if approved by its commissioners, would be issued jointly with the product manufacturers. CPSC may also work with the manufacturers to develop voluntary standards to modify the equipment. If a "substantial" hazard is established, CPSC has the authority to recall cordless telephones. At the point, the FCC could take the equipment off the market by revoking the certification to sell it.

Readers are urged to help investigate the extent of the hazard cordless telephones pose on hearing. Write to Dr. Jerome C. Goldstein, Academy Deputy Executive Vice President at the Academy office. You are requested to supply as many details as possible, including the brand and model of the equipment, and the patient's name if he or she would be willing to discuss the case with the CPSC. The collected case reports will be presented to the CPSC with appropriate recommendations. The Academy has also notified the FDA's Bureau of Medical Devices of the emerging medical hazard related to cordless telephones.

The Executive Committee of the American Auditory Society has announced the availability of Life Membership in our organization.

Eligibility requirements include membership status for ten consecutive years and an age of seventy years or more (we won't tell!)

For further information contact: Ross Roeser, Ph.D., Secretary/Treasurer AAS, 1966 Inwood Rd., Dallas, TX 75235.

Diller To Lead 1984 Campaign For Better Hearing and Speech

Popular comedienne Phyllis Diller, who overcame a hearing problem herself, will lead the Council for Better Hearing and Speech Month's 1984 public information campaign on behalf of 22 million Americans with communicative disorders. She was elected national chairman of the May campaign by a consortium of 27 nonprofit hearing and speech organizations cooperating in the Council program.

Miss Diller will act as chief media spokesman for the Council's message of hope and help for those suffering from hearing and speech problems. She personally experienced a sudden hearing loss which was corrected by medical therapy, and has since committed herself to helping others with similar problems.

Miss Diller will launch the Council campaign during early May kickoff ceremonies in Washington, D.C., where she will release a special message from President Reagan, introducing the 1984 poster child, and step up a series of national media appearances.

Killion Launches Etymotic Research, Inc.

Mead Killion, Ph.D., has announced the formation of Etymotic Research, Inc., a new company to do Research and Product Development in the hearing instruments field. "We have been extremely fortunate," says Killion, "that Knowles Electronics has granted us the development rights to three important new products on which I worked. We hope to bring out the first one early in 1984."

Killion has spent 21 years in the hearing aid industry. He helped develop the first subminiature ceramic microphone, the subminiature electret microphone, and subminiature directional microphones. He is probably best known for developing earmold coupling systems to improve both the useful bandwidth and the sound quality of hearing aids. He has been granted eight U.S. patents, either as sole inventor or with co-inventors, and has two more pending.

Killion is an Adjunct Professor of Audiology at Northwestern University. He has written and lectured extensively on hearing aids and earmolds, with papers published in the field of electroacoustics, psycho- and physiological acoustics, and audiology.

The corporate name ETYBOTIC is pronounced et-im-OH-tik. It is a newly coined "ancient Greek" word, which here means "true to the ear." The corporate name reflects Killion's commitment to unflawed sound reproduction for the normal or impaired ear.

The Board of Directors of Etymotic Research includes Charles I. Berlin, Ph.D., Jack Clemis, MD, Barbara Kruger, Ph.D., E. Robert Libby, Edgar Villchur, and Laura Wilber, Ph.D.

Inter Noise 84

The Institute of Noise Control Engineering (INCE-USA) has issued the Announcement and Call for Papers for INTER-NOISE 84. INTER-NOISE 84, the 1984 International Conference on Noise Control Engineering, will be the thirteenth in a series of International Conferences on Noise Control Engineering which began in 1972 in Washington, DC. INTER-NOISE 84 will be held at the Hotel Ilikai in Honolulu, Hawaii on December 03-05, 1984. Deadline for receipt of abstracts is March 15, 1984.

Copies of the Announcement and Call for Papers are available from the INTER-NOISE 84 Conference Secretariat, P. O. Box 3469, Arlington Branch, Poughkeepsie, NY 12603, USA.

ARA Holds Fall Meeting

The fall meeting of the Audiological Resource Association was held in Roan Mountain, Tennessee, on October 22 and 23. Derek Sanders, Ph.D. presented a stimulating program on aural rehabilitation with a focus on the provisions of services in a private practice setting. Dr. Sanders stressed that the audiological work-up is only the first step in determining rehabilitation needs. He encouraged the clinician to take into account the total communication needs of each individual as well as the motivating factors in seeking amplification. The emotional effects a hearing loss has on a client and the changes in the client's self-concept that occur with amplification must be considered as well.

The meeting was well attended and all were very grateful for the financial support provided by Siemens Hearing Instruments.

The meeting site was a rustic mountain setting. Fall colors were near their peak and many attendees took advantage of the hiking trails in the park. The setting and atmosphere was so attractive that Roan Mountain was unanimously chosen for the Fall 1984 meeting.

ADA Adopts Position Statement

(ED NOTE: On November 18, 1983 The Academy of Dispensing Audiologists Adopted the following Position).

The purpose of this position paper is to create a specific definition of the professional responsibilities and capabilities of a practicing Audiologist. It also presents ADA positions on related professional issues.

I. Hearing Loss & Audiologists

A. Hearing loss warrants concern both as a symptom of bodily dysfunction and as a potential communicative disability. The best interests of the public are served by recognizing that any person with a hearing loss that is determined not to be medically or surgically remediable should be under the management of an Audiologist.

B. An Audiologist may practice in a variety of professional settings. The Academy of Dispensing Audiologists recognizes the independence of Audiology as a profession whether practiced as a private enterprise or in association with hospitals, universities, or other related professionals.

C. The Audiologist is the best qualified professional practitioner to assume the responsibility for the non-medical habilitation/rehabilitation of the hearing-impaired person, including, but not limited to counseling of the hearing-impaired and their families, aural habilitation/rehabilitation, and the evaluation, selection and fitting of appropriate amplification and tinnitus masking instrumentation.

D. Of those professionals who generally provide services to the hearing-impaired, only the Audiologist is trained and experienced in planning and implementing a complete program of aural habilitation/rehabilitation. Therefore, the Audiologist should be the professional practitioner who carries out or supervises such a program.

E. A hearing aid is only one part of an overall program of aural habilitation/rehabilitation.

II. Auditory Tests

A. Although the information obtained through audiometric tests is frequently utilized by physicians to reach a medical diagnosis, such tests are not in and of themselves medical tests. As procedures for the evaluation of the auditory sensory modality, tests of auditory function can provide rehabilitation-specific as well as medically specific information.

B. Audiometric test batteries provide differentially diagnostic information that is vitally important in determining etiology and site-of-lesion of hearing loss.

C. The Audiologist is best qualified by training and experience to determine which acoustic and non-acoustic tests of the auditory sensory modality are appropriate in individual cases, to administer or supervise the administration of such procedures, and to provide such information to the patient's physician to assist in the medical remediation and/or treatment of the patient.

**IMPORTANT ISSUES
RESOLVED AT AAS
EXECUTIVE COMMITTEE
MEETING. (See Page 4)**

CORTI'S ORGAN is a publication of the American Auditory Society, processed in Dallas, Texas.

CORTI'S CALENDAR

February 6-8, 1984

Primary Children's Medical Center will sponsor a conference at Snowbird, Utah, on advances in pediatric sensory evoked potentials as they apply to neonates and young children. Guest faculty include Kurt Hecox, M.D., Ph.D., Kenneth Nudleman, M.D., and Samuel Sokol, Ph.D.

For further information, please contact Michael J. Cevette, Primary Children's Medical Center, Speech/Language/Hearing Center, 363 12th Avenue, Salt Lake City, Utah 84103, (801)521-1680.

March 4-10, 1984

The 18th Colorado Otolaryngology-Audiology Workshop will be held March 4-10, 1984 at the Continental Inn and Aspen Conference Center in Aspen, Colorado.

For further information contact: Jerry Northern, Ph.D., Colorado Hearing Foundation, Box B210, 4200 E. 9th Avenue, Denver Colorado 80262.

June 6-9, 1984

Academy of Rehabilitative Audiology Summer Institute: Computers in Aural Rehabilitation. Watts Bar Dam, Tennessee.

Contact: Lloyd Graunke, Ph.D., 1008 Grace Drive, Johnson City, TN 37501.

June 24-28, 1984

The International Federation of the Hard of Hearing (IFHOH) arranges in cooperation with Hørselramjandets Riksförbund, Sweden "The 2nd International Congress of the Hard of Hearing" at Folkets Hus in Stockholm, Sweden.

More information of the Congress will be given by the Congress Secretariat, 2nd International Congress of the Hard of Hearing, c/o RESO Congress Service, S-105 24 Stockholm, Sweden. Telephone: +46-8-14 49 10.

August 26-30, 1984

International Congress of Audiology and American Auditory Society joint meetings, Santa Barbara CA.

Contact: Sanford E. Gerber, Ph.D., Chairman, Dept. of Speech, University of California, Santa Barbara, CA 93106.

October 21-22, 1984

Audiological Resource Association Fall Meeting Topic: "Aural Rehabilitation" Roan Mountain, Tennessee

Contact: Faye Churchill, Suite 402, 2022 Brookwood Medical Center Drive, Birmingham, Alabama, 35209.

Letter From England

January 1st, 1984. I wish you and your readers, wherever they might be, a happy and prosperous New Year.

We hope you have been able to enjoy the festivities in your snowed-in 'igloo'. We have been worried about your weather.

But I am sure you have been well prepared for the weather as people in colder unfriendly climes. Why should we not be prepared against other threatening dangers? Would a shovel do where not even snowploughs can get through...?

In contrast we have been enjoying a comparatively mild December and the New Year has begun, at least climatically speaking, in a pleasant way also. Let us hope that it is a good omen in spite of the sinister reputation of the number '1984'. Our Prime Minister believes that Orwell's grim forecasts in his book '1984' were wrong.

The health services will have to brace themselves to considerable economies. What is even more alarming is the fact that more of the newly qualified doctors have been finding it difficult or impossible to get jobs. There are many old hospitals in London facing closure; some have perhaps reached the end of their usefulness. But it is a disturbing thought that one or two hospitals that have been looking so well after the victims of the recent bomb-outrage at 'Harrods' — known to visitors from the USA — may have to be abolished. In my opinion there could never be too many doctors and hospitals anywhere. Efficiency could, of course, be improved and wastage should be eliminated as also unnecessary treatment curtailed, but progress must not be retarded.

That good and indeed excellent work can be carried out under difficult conditions has been demonstrated once again, on a hospital-ship providing medical care near the Falklands in the Atlantic; over 700 wounded were treated on her and only 3 of them died. One of our naval colleagues served on the ship, a converted cruise liner. I was interested to note that the cockpit bar had to be converted into the path, lab.

A new audiological unit has been opened in my old hospital, the Royal National Throat Nose and Ear hospital in London and Professor Ron Hinchcliffe has been occupying there an up-to-date modern department of audiological medicine. The building houses the hearing-aid centre also. I am happy to have witnessed the great renaissance of otolaryngology in the last 35 years.

Countless publications have appeared and many excellent new journals have been founded. Nevertheless, the older established journals retain their leading position. This has been recognized in the person of the popular Editor of the Journal of Laryngology and Otolaryngology (England) Mr. John Chalmers Ballantyne by his appointment at CBE: Commander of the British Empire; one of the highest honours awarded by the Queen in this year's Honour's list. I am sure all John's friends and admirers all over the world will be delighted in his award so well merited.

Your readers might be interested that with John Ballantyne we have edited an 'Ultrastructural Atlas of the Inner Ear', with the active cooperation of many experts in this field including David Lim, Bob Kimura, Hanna Sobkowicz, I. Hunter Duvar, from the USA and Canada. The Atlas will be published by Butterworths in the near future.

Last year I have paid another visit to the House Ear Institute which has been refurbished and reorganized to house a paediatric unit for cochlear implantations under Bill House who has succeeded Howard as President of the Institute. Another example of relentless progress that has characterized the House Institute; also the ENT-department at the UCLA under Paul Ward and Vincente Honrubia.

I hope we shall both be able to continue observing the passing parade of our chosen specialties in PEACE.

Imre Friedmann

Inter-Noise Proceedings Available

The first of the well-known series of INTER-NOISE Conferences on noise control engineering was held in Washington, DC in December, 1972. Since the first meeting, eleven annual INTER-NOISE Conferences have been held in seven different countries, and world-wide interest in noise control technology has grown rapidly. The Proceedings of the INTER-NOISE series have been an important source of information on noise control technology for many years.

All of the Proceedings of past conferences are still available, and a reduced price is now available for a limited time for nearly all volumes. The list prices of these volumes have been reduced by 25%-35% until June 30, 1984. This is the last time that a complete set of INTER-NOISE Proceedings will be available.

A flyer which describes the volumes in the series and contains ordering information may be obtained from the Institute of Noise Control Engineering, P.O. Box 3206, Arlington Branch, Poughkeepsie, NY 12603, U.S.A.

**Computer Applications
Topic Of ARA Meeting**

The winter meeting of the Audiological Resource Association will focus on the use of computers in the audiology practice. Topics to be covered will include an introduction to computer terminology and concepts, hardware, configurations, a review of software, computer supplemented BSE testing, computerized hearing aid selection, adapting software to the audiologists need, business applications, and computerized industrial services. Bruce Weber, Ph.D., Duke University will also provide an update on Brain Stem Evoked Potential Testing.

The meeting was planned in recognition of the growing value of the computer to business applications as well as other aspects of an audiology practice. The group hopes to demonstrate the broad application of today's computers and dispel, to some extent, the common fear that complex training is required before one can work with a computer. The "USE FRIENDLY" design of current equipment allows one to quickly adapt a computer to suit the individual need of each practice. The participants will have an opportunity for "hands-on" experience to demonstrate this flexibility. Attendees are expected to raise their level of computer literacy — a definite requirement for survival in the 80's.

The meeting will take place in Gatlinburg, Tennessee, the traditional site for the group's February meeting. Gatlinburg is a beautiful resort town nestled in the Smokey Mountains. The abundance of quaint stores, craft centers and outdoor activities makes this a great site for a "working vacation".

Registration will be open to all interested individuals. However, register early as enrollment is limited to 100. Further information may be obtained from the ARA Secretary, Mary Faye Churchill, Suite 402, 2022 Brookwood Medical Center Drive, Birmingham, Alabama 35209.

**G.A. Levow, Inc. To
Sponsor Downs Seminar**

G.A. Levow, Inc. is pleased to sponsor a seminar entitled "Otitis Media and Its Effect on Learning". The seminar scheduled for April 7, 1984 at the Aspen Hotel and Manor in Parsippany, NJ will be conducted by Marian P. Downs, M.A., D.H.S., Professor Emeritus of Otolaryngology-Audiology at the University of Colorado.

In addition to Mrs. Downs, Dr. Francis T. Deane, MD will speak on the medical aspects of otitis media. Three teachers from the Kinnelon, NJ Public Schools will discuss teacher observations of otitis media and its effect in the classroom and several parents will be on hand to provide observations from the parents' point of view.

For additional information or to obtain a registration form contact: Ron Gardrel, G.A. Levow, Inc., 44-48 Mechanic Street, Newton, MA 02164. 1-800-225-4270.

ABR Symposium Announced

A unique symposium will be held this Spring in Washington, D.C. Entitled "Clinical Problems and Issues in Auditory Brainstem Response Audiometry", this meeting will have invited guest speakers and no scientific papers. Its purpose will be to bring together 50-100 experienced users of ABR audiometry to permit the sharing of successes, failures, problems and questions.

The organizers of the meeting, Roger Ruth of the University of Virginia Medical Center and Bruce Weber of Duke University Medical Center, believe that often the most valuable portion of a workshop or scientific meeting is the informal interchange that occurs outside the structured meetings. Unfortunately, this exchange of information is usually very brief and haphazard. In an attempt to provide an alternative to conventional meetings, last spring Drs. Ruth and Weber organized an inexpensive two and a half day symposium aimed at the informal sharing of clinical information about ABR Audiometry. The meeting, on an invitation basis, attracted 100 clinicians from around the country. The symposium consisted of panel discussions. Because the size of the group was limited it permitted considerable interaction among the participants. The meeting was considered to be such a success that it will be held again this spring with an open invitation extended to any professional who is actively involved in clinical ABR audiometry. It will be held on May 25-27 in Washington D.C. For more information contact: Dr. Roger Ruth, Dept. of Otolaryngology, Box 430 University of Virginia Medical Center, Charlottesville, VA 22908.

"Beethoven's Deafness"

By E. Robert Libby

In each of the arts, there are a few figures who loom imposingly over all the others. Beethoven's name is the one which automatically springs to most people's minds if asked to name a musical composer.

Neither the practice of medicine nor for that matter, the practice of hearing aid fitting would be perceptibly affected by the knowledge or ignorance of Beethoven's deafness. Nevertheless very few illnesses have aroused such speculation and interest as his hearing loss. His grave was opened twice in an attempt to solve the riddle of his deafness.

Beethoven was born in Bonn, Germany, in 1770. He showed early musical genius. At age eight he gave his first concert. At 12 he was already publishing promising compositions.

Beethoven, who previously enjoyed exceptional hearing, began to experience deafness for high tones when he was 27 years of age. He complained of ear infections. In 1801, when he was 31 years old he stated in a letter to a friend: "Know that my noblest faculty, my hearing, has greatly deteriorated. When you were still with me I felt the symptoms but kept silent. Now it is continually getting worse. My affliction causes me the least trouble in playing and composing, the most in association with others."

Another letter also written in 1801: "My hearing has grown steadily worse for three years, my ears whistle and buzz continuously day and night. In any other profession, this might be more tolerable, but in mine such a condition is truly frightful...to give you some idea of my extraordinary deafness I must tell you that in the theatre I am obliged to lean close up against the orchestra in order to understand the actors, and when a little way off, I hear more of the high notes of instruments or singers."

If I am a little farther away, I do not hear at all. Frequently I can hear the tones of low conversation but not the sounds of the words and soon as anyone shouts it is intolerable."

Stevens and Heinenway describe Beethoven's symptoms: The left ear was the first to become involved, but soon became a bilateral high frequency hearing loss, associated with severe tinnitus. His discrimination appears to have been poor. Recruitment is suggested by his intolerance to loud sounds. He never had vertigo or purulent otitis.

Hearing Devices

It is of interest that Beethoven used various devices to aid his hearing. Despite his poor discrimination he made extensive use of ear trumpets. He has trumpets designed which were held in place by a special headband. The Beethoven Museum in Bonn has on display a number of ear trumpets which the composer is known to have used.

Gelleneau describes a wooden "drumstick," reputedly used by Beethoven, one end of which was held between the teeth and allowed hearing by bone conduction and suggests a conductive component to his hearing loss. It may be noted that sound conducted via the teeth may be a more efficient bone conduction route than that via the mastoid, or the skull, particularly for low frequency sounds.

Beethoven's deafness progressed until it became profound. Despite its severity, he continued to use his wooden drumstick and ear trumpets until his death, suggesting that his deafness never became total. One wonders how present day electronic amplifiers would have affected Beethoven's genius and changed the course of musical history?

The only efficient means by which Beethoven could communicate in his later years was by writing; for this purpose he used conversation books in which he left an invaluable record of his life. Of the 400 known conversation books, only 136 remain. His friend Shindler unfortunately destroyed most of them for possible political reasons.

It should be noted that his speech did not deteriorate and remained intact until the end.

Medical History

The cause of Beethoven's deafness still remains a mystery. Many theories have been advanced but none have been proven conclusively. Of the possible diagnoses, including syphilis, ty-

phoid fever and vascular insufficiency, only cochlear otosclerosis as a single otological disease can explain all the clinical symptoms and pathological findings. Larkin also favors the diagnosis of otosclerosis. In an entirely different view, Maiken views Beethoven's deafness in the context of Paget's disease of bone. The unusual physical characteristics — large asymmetrical head, large Olympian forehead, overhanging browns, thick fingers — all suggested Paget's disease.

Miller states we should consider trauma as a possible cause. The young Ludwig was forced by his greedy, drink-crazed father to practice hour after hour. At times the elder Beethoven would drag the young Ludwig out of bed and make him play until dawn. Blows on the head followed the slightest mistake caused by lack of sleep, cold or fatigue. Some of the complex mechanisms of auditory perception could be damaged by repeated blows at the temporal region close to the petrous position. Such cases are by no means rare.

The older view accepts that Beethoven's deafness was caused by syphilis. The view we suspect was responsible for much of the fascination evoked by the composer's hearing loss. The stigma of venereal disease adds of touch of tragedy.

In 1863 and again in 1888 the grave was opened and the skull was examined. Unfortunately Beethoven's temporal bones were missing.

The Psychology of Beethoven's Deafness

Anyone who has closely observed an adult soon after he has lost his hearing has noted that he becomes discouraged and struggles with feeling of depression. He may become suspicious of friends and family. He not only loses his communication ability, but suffers from a basic and severe psychological impairment. There is an undefined feeling of loss coupled with a vague sadness and insecurity. Beethoven had all these classic symptoms. The realization that he was threatened with deafness threw Beethoven into a depression which nearly drove him to suicide. His "Heiligenstadt Will," written for his brother in 1802, is an impressive and moving document of inner self conquest and rededication to music.

Deafness, of course, severely increased the suspicion and pride already natural to him. It finally all but severed his relations with the outside world. He was exposed to crass misunderstanding as he became increasingly engrossed in the inner world of his musical imagination. Social intercourse became increasingly difficult with friends and even more with constantly changing servants.

Goethe remarks about Beethoven's character: "One must forgive him and pity him for his loss of hearing, which is perhaps less harmful to him from a musical than from a social viewpoint. Never have I met such a concentrated, forceful and fervent artist. I can well understand that he has a strange relationship with the world." In his last years Beethoven was darkly moody and eccentric, and spend many long years in brooding solitude.

Relationship of Beethoven's Deafness and His Music

Allowing for the idle quality of curiosity, we must look beyond for a deeper cause of lasting interest in Beethoven's deafness. This clue may be found in the harsh irony of fate which deprived a musical genius of his sense of hearing. When the poet Milton became blind his daughter wrote and read for him. No one, however, could help Beethoven. Yet he still created immortal music.

Beethoven's symptoms first appeared in 1797. The first symphony was published in 1800. No hint of tragedy appears in it. Even as his hearing deteriorated and hope for improvement declined, he was busy preparing the ground work for his future creations. The sketches of the first three movements of the Fifth Symphony were begun around 1800. The Prometheus theme with which Beethoven concluded the Eroica was completed during this period.

The summer of 1802 was a critical one for Beethoven. There is little doubt that Beethoven was close to despair at this time over the calamity that had overtaken him. Despite his despair he was sustained by his art. Actually the affliction in no way interfered with his creative ability. It tended to isolate him from society and it increased his feelings of loneliness. It may explain in part why his longing reached out to nature and the universe more than to his fellow man for inspiration. The history of Beethoven's later years is almost entirely that of music. By 1810 when his deafness had isolated him, he had completed the Emperor Concerto and was engaged in the Seventh Symphony performed in Vienna in 1813.

By the time Beethoven composed what many consider his masterpiece, the Ninth Symphony, his deafness was a way of life. He nonetheless conducted the first performance of this work hearing neither music from the performance nor accolades from the audience.

Conclusion

Beethoven led an intense, sometimes anguished and agonizing, sometimes joyful, but always exciting and controversial life. All this is reflected in his music. He is buried in a quiet circle in Vienna's Central Cemetery, the final resting place for all of Vienna's famous composers and musicians. As would be expected, his monument dominates all others.

Perhaps his struggle against forbidding odds, more than the cause of his deafness, deserves deeper wonder and further exploration.

BUYER'S GUIDE

Integrated Systems for Clinical Care

TRACOUSTICS' Integrated Clinical-Diagnostic Systems provide the utmost in capability and economy. The TRACY Evoked Potential System presents the ultimate in obtaining, analyzing and storing auditory evoked potentials at the lowest price in the industry. EARSCAN opens new vistas to the measurement of middle-ear immittance and reflexometry. The PROGRAM III Clinical Audiometer holds its place as the first and most full-featured micro-processor based audiometer available.

Continue to look to TRACOUSTICS for the highest quality in Audiometric Rooms and Suites with a complete line of enclosures for clinical, medical and research use. We have the flexibility to design a Room or Suite to meet most any need or budget. Our planning assistance will save you space, our shipping schedule will save you time, and our designs will save you money.

Increase diagnostic capabilities with the addition of a TRACOUSTICS ENG System, complete with a mobile integrated cart, ENG examination table, and a digital light bar with stationary, optokinetic and pendular targets.

Minutes Of The American Auditory Society Executive Committee Meeting

DATE: November 16, 1983

PLACE: Netherlands Plaza Hotel, Cincinnati, Ohio

TIME: 1:30 P.M.

MEMBERS PRESENT: Charlie D. Anderson, Lavonne Bergstrom, Earl Harford, Ed Johnson, Susanne Kos, Ralph F. Naunton, Ross J. Roeser, Hiroshi Shimizu, Don Worthington.

MEMBERS ABSENT: Bruce Graham, Malcolm Grahm, William Meyerhoff, James A. Nunley, W. Dixon Ward, Marion Downs.

GUESTS: Irvin Gerling, David Lipscomb, Deborah Hayes, Bruce Weber, Michael Seidemann, Robert Keith, Cy Libby, Phillip Bellefleur, Eugene Sheeley, Suzanne Brown.

1. President Anderson opened the meeting at 1:38 p.m.
2. The first order of business was to welcome the new Executive Committee members, several of whom were present at the meeting. The new members are:

- A. F. Owen Black
- B. Deborah Hayes
- C. E. Robert (Cy) Libby
- D. David Lipscomb
- E. James Pappas
- F. Michael Seidemann
- G. Wayne Staab

3. The minutes from the 1982 meeting of the Executive Committee were approved.

4. The treasurer's report from January-October, 1983 was discussed and approved with one change.

5. A report on the membership was given. The total number of members as of October 30, 1983 was 1319. Of these, 1173 (88%) are audiologists, 127 (10%) are otolaryngologists, and the remaining (2%) are in other categories. The promotional netted 264 members for 1983 and 1984, 212 were audiologists and 52 were otolaryngologists.

6. The 1984 meeting site was identified last year to be Santa Barbara. AAS will meet with the International Audiology Society. A committee was formed consisting of Lavonne Bergstrom, Cy Libby, Hiroshi Shimizu, and Don Worthington to identify the Carhart Memorial Award recipient for the 1984 individuals were identified and the Executive Committee voted on these two individuals. The recipient was contacted and agreed to present the Carhart Memorial Lecture in Santa Barbara. He is Gunnar Liden.

7. A discussion was held regarding the 1985 and 1986 meeting sites. It was decided that the 1985 meeting would be held in Atlanta with the American Academy of Otolaryngology/Head & Neck Surgery. David Lipscomb was identified as the Chairman for the Scientific sessions. Tad Zelski was identified as the Local Arrangements Chairman.

The 1986 meeting will be held in Detroit with ASHA.

8. Ross J. Roeser was appointed as Secretary/Treasurer for 1985.

9. Susanne Kos was appointed as Assistant Secretary for 1985.

10. A report on **Ear and Hearing** was given by Ross Roeser.

A. A statistical summary of the manuscripts received during the period 1980 through 1983 was reviewed. Overall 290 manuscripts were received during this period. During 1982 there were more manuscripts received than any other year, and there continues to be a healthy flow of manuscripts.

B. Appreciation was expressed to the Section Editors and Editorial Consultants. A listing of the Editorial Consultants appears in the November/December issue of the journal and Executive Committee members were encouraged to contact these people and express their appreciation for their work on **Ear and Hearing**.

C. Ken Startt, representative from the Williams and Wilkins Co., gave a financial review of the journal from the publisher's perspective. All indications are that the journal is on a sound financial basis and this implies that there will be no increase in the subscription rate for members in 1984 or 1985. Thus, there will be no increase in dues for this period.

D. A controversial manuscript was submitted to the journal in 1982. The issue was discussed with the Executive committee, which resulted in approval of the manuscript for publication.

E. The Executive Committee approved a transfer of \$1000.00 from the AAS account to the **Ear and Hearing** account.

F. The Editorial board will remain the same for 1984. For 1985 Ross Roeser indicated that he would relinquish the post of Editor-In-Chief and recommended that the Executive Committee accept Robert W. Keith's offer to serve in this position. After discussion a motion was made to accept Robert Keith as the Editor-In-Chief for a five year period. This motion passed.

G. At the meeting of the Editorial Board the presentation of Editorial Awards were discussed and several members indicated that they felt that **Ear and Hearing** should discontinue granting Editorial Awards for outstanding papers. Several opinions were given both for and against the granting of Editorial Awards. After this discussion it was moved that **Ear and Hearing** discontinue giving awards for outstanding papers that are published in **Ear and Hearing**. This motion passed.

11. Marion Downs had contacted President Anderson prior to the meeting and indicated that she wished to discontinue her post as the Editor of **Corti's Organ**. Suzanne Brown, Associate Editor for **Corti's Organ**, was present and indicated she would accept the post if the Executive committee would approve her. Following discussion she was appointed the Editor of **Corti's Organ**. She indicated that her plans were to keep the publication in its present form, but did want to make several changes including changing the Regional Editors, publication of more information on national events, and trying to bolster advertising in the newsletter to offset costs.

12. It was brought to the attention of the Executive Committee that since AAS had been in existence for 10 years it now was possible for members of the Society who had attained the age of 70 years and had held membership for 10 consecutive years to become Life Members of the Society. In order to do so the candidate must contact the Secretary/Treasurer and request Life Membership. An announcement will be placed in **Corti's Organ** to inform members of this.

13. Several Chairmen gave committee reports.

A. **Committee on Committees** — Ralph Naunton reviewed the activities of the Committee on Committees since the 1982 Executive Committee Meeting. He indicated that his committee had identified several standing committees of the Society including a Committee on Standards, Membership and Credentials Committee, Public Relations Committee, Long Range Planning Committee, Program Committee, and Annual Meetings Committee. The recommendation of these committees was submitted to President Anderson.

President Anderson indicated that he and Ross Roeser met in June to discuss these possible committees and felt that three Committees should begin their activities immediately. These committees were the Membership Promotions Committee, Standards Committee, and Credentials Committee. Chairmen of these three were identified and accepted the posts.

B. **Membership/Promotion Committee** — Don Worthington was appointed the Chairman of the Membership/Promotions Committee. He indicated that his committee would like to develop a display for the Society and have it placed at national meetings to attract new members. He had contacted representatives from ASHA, AAO, and the National Hearing Aid Society to estimate costs and found it would cost between \$130.00-\$560.00 to obtain a booth at these meetings. After discussion it was decided that AAS would construct an exhibit to display at meetings. The first meeting targeted was the International Audiology Society in Santa Barbara in 1984. It was also decided that in 1984 the Society would send out a promotional similar to past years to the professionals in the education of the deaf. The budget set for promotional activities for 1984 was \$3,600.00.

C. The **Standards Committee** will be chaired by W. Dixon Ward. He was not present for the meeting, but through correspondence indicated that he would accept the Chairmanship. Whether AAS should have a Standards Committee, and the exact function of the committee was discussed, and after discussion it was agreed that this was a major change in the direction of the Society and should be approached cautiously. One proposal has been made to write a standard on impedance screening and it was decided that AAS would pursue this particular endeavor. It was also suggested that the Committee explore avenues for AAS to be included on various writing groups.

D. The **Credentials Committee** will be chaired by Susan Kos. She indicated that she and one other member have viewed all applicants since the 1982 Executive Committee Meeting. She has categorized the members into those with sponsors' signatures, those without sponsors' signatures who belong to ASHA or AAO, and those without sponsors' signatures who do not belong to ASHA or AAO. In total there were 275 new members approved for 1983, and this list will be published in **Corti's Organ**.

After reviewing the activities of the three committees it was decided that a Long Range Planning Committee was needed and President Anderson appointed Ralph Naunton as the Chairman of the committee.

14. The possibility of purchasing video equipment to tape the annual meeting was discussed. It was pointed out that having video equipment would allow the Society to tape meetings, including the Carhart Memorial Lecture, for distribution to the members who could not attend and for historical reasons. After discussion it was felt that this should be taken up for the 1984 meeting in Santa Barbara to determine its merit prior to equipment purchase. Earl Harford volunteered to coordinate this project.

15. The Society received a letter requesting its participation in Better Hearing and Speech Month. It was unanimously agreed that this is a highly worthwhile endeavor, but due to the costs involved more thought was needed on becoming a sponsoring organization for this activity. The Society has sponsored any other organization to date.

16. A representative from the CRS Amplifon Award contacted the Society just prior to the meeting and asked for support of a candidate. This year's prize will be awarded to a clinician/researcher in the area of the vestibular system. Awards Committee has already identified a possible candidate and requested that the Society concur with the selection. It was pointed out that this is a worthwhile activity but due to the short notice given to the Society, the Society would not suggest additional names. It was also stated that AAS should ask the CRS Amplifon Committee to contact the Society earlier so that serious thought can be given to a candidate.

17. Recognition was given to the Beltone Distinguished Teaching Award activities that were to be held at this year's annual meeting. Although some possible conflicts were pointed out, it was felt that this is a worthwhile activity and should be supported by AAS.

18. President Anderson recognized the departing Executive Committee Members. These included Malcolm Grahm, Bruce Graham, Ed Johnson, Ralph Naunton, and Hiroshi Shimizu. He expressed his deep appreciation for their work and efforts that have been put forth for the Society.

19. There being no other immediate business the Executive Committee adjourned at 5:37 p.m.

AMERICAN AUDITORY SOCIETY Statement of Income and Disbursement for 1983 10/31/83

Revenues

1. Prepaid Membership dues (587 total)	\$20,545.00
2. Membership dues for 1983	23,331.00
3. Interest on checking and savings accounts	1,349.00
4. Convention income	4,724.00
5. Selling Mailing list	80.00
*posted through 9/15/83 only	
TOTAL	\$50,029.00

Expenses

1. Expensible supplies	\$1,288.00
2. Office equipment	384.00
3. Postage for office	1,035.00
4. Postage for Corti's Organ	460.00
5. Printing and duplicating	277.00
6. Telephone	447.00
7. Travel-office	254.00
8. Corti's Organ costs	2,359.00
9. Bookkeeping and audit	135.00
10. Contract services-office	949.00
11. Contract services-Corti's	512.00
12. Convention expense-1982	460.00
13. Convention expense-1983	2,277.00
14. Supplies and equipment-Corti's	157.00
15. Secretary/Treasurer allowance	1,800.00
16. Ear and Hearing Costs	30,829.00
17. UTD Indirect Costs	65.00
18. Foreign check charge	7.00
19. Promotional for 1983	3,283.00
20. Credentials Committee	168.00
TOTAL EXPENSES	\$47,146.00

NET INCOME **\$2,883.00**

Assets	
Checking	\$11,396.00
Savings	\$24,494.00
	\$35,890.00

Minutes of the Ear And Hearing Editorial Board Meeting

DATE: November 16, 1983

PLACE: Cincinnati, OH

MEMBERS IN ATTENDANCE: Phillip A. Bellefleur, Irvin J. Gerling, Deborah Hayes, Robert W. Keith, Ross J. Roeser, Eugene Sheeley, Hiroshi Shimizu, and Bruce A. Weber.

MEMBERS ABSENT: William Meyerhoff

OTHERS IN ATTENDANCE: Charlie D. Anderson, President of AAS, Ralph Naunton, Executive Committee.

1. The meeting began at 10:40 A.M.

2. The meeting began by reviewing statistical summaries showing manuscripts submitted for the period January, 1980 to September, 1983. The first summary showed the cumulative number of manuscripts received during this period. The date indicated that there had been 290 manuscripts submitted to **Ear and Hearing** during this period. The second analysis showed the cumulative manuscripts received by month. It was clear that in 1982 more manuscripts were submitted than other years. However, there continues to be a healthy flow of submitted manuscripts, with 70-80 expected manuscripts to be submitted in 1983.

The next two statistical summaries reviewed the status of the 1983 manuscripts. The primary information from these summaries was that the regular section received the most number of submitted manuscripts, the electrophysiologic and speech sections received the greatest number of manuscripts of the sections, and the otology and hearing education sections have yet to receive any submitted manuscript for 1983.

3. Ken Startt, Vice President for Periodical at the Williams and Wilkins Co., and the publishers representative for **Ear and Hearing**, gave a financial report. Circulation has increased significantly in the past year, making the financial outlook for the journal excellent. Based on projections, it was indicated that there will be no increase in publication costs for 1984 or 1985.

4. Plans for 1984 and 1985 were reviewed. It was stated that for 1984 the Editorial Board would remain the same. Ross Roeser indicated that he planned to vacate the post of Editor-in-Chief after Volume V (1984) had been completed and recommended that Bob Keith be appointed to this post. It was indicated that this was an Executive Committee decision and would be discussed later in the day during the Executive Committee meeting.

5. A discussion was held on the editorial Awards for Outstanding Papers. There was concern raised regarding the awards in general and several members of the Editorial Board indicated that they would prefer not giving awards. After discussion, this issue was put to vote and there were four in favor and four against giving awards. It was decided that the issue would be discussed at the Executive Committee meeting later in the afternoon, as it was an Executive Committee decision to give the awards.

6. A list of the Editorial consultants for the 1983 journal was provided to each member to review. One change was made. It was stated that the Editorial Board should express their appreciation to their Editorial Consultants for the work they have done with the journal.

7. Each Section Editor gave a report on the section which he/she edited. The only major concern raised was that two sections, the Audiology in Hearing Education and New Developments in Otology sections, were not receiving any submitted manuscripts. Based on this, it was decided to recommend to the Executive Committee that next year the deaf educators be targeted to receive promotional material on the Society. Bill Meyerhoff had written a letter to the members of the Society of Academic Otolaryngologists in September, but it is too early to determine the effects of this action.

8. A controversial manuscript was submitted to the journal in 1982. The manuscript involved a comparison of manufacturers' products and found that one product was not rated as high as it was advertised. After discussion, the Editorial Board unanimously approved the publication of this manuscript.

There being no other business the meeting was adjourned at 12:10 p.m.

ADA ADOPTS

cont. from page 1

III. Procedural Statements

- The Academy of Dispensing Audiologists supports the position that the Audiologist is the person best qualified by training and experience to perform or supervise the management of persons with non-medically treatable hearing impairments.
- The Academy of Dispensing Audiologists supports that provision of the U.S. Food and Drug Administration regulations concerning hearing aids that encourages persons considering the purchase of hearing aids to have a medical examination prior to such a purchase.
- It is in the interest of individuals suffering from Tinnitus that they undergo thorough otological and audiological evaluations prior to being considered a candidate for tinnitus maskers or hearing aids.
- Public health or industrial health programs which concern themselves with the prevention or management of noise-induced sensorineural hearing loss should be under the supervision of an Audiologist or physician trained in hearing conservation and the organization and administration of such programs.

IV. Certification & Licensing

- The requirements for the Certificate of Clinical Competence in Audiology of the American Speech-Language-Hearing Association are the most comprehensive audiological training standards currently in effect and should be references as part of national or state licensing or service provision regulations.
- The Academy of Dispensing Audiologists supports the licensing of Audiologists on the grounds that licensing enables the public to identify qualified professionals capable of assisting them in the non-medical management of hearing impairments.

V. Public & Professional Education

- The Academy of Dispensing Audiologists supports communication with unions, management, negotiators, Medicaid, Medicare, governmental agencies, television, and radio programs and personalities, newspaper columnists, state and national legislators, research organizations, public service organizations, and the public, to inform them of the ability of audiologists to advise and assist in any matters dealing with the non-medical management of hearing loss.
- The Academy of Dispensing Audiologists supports the efforts of any professional or public interest organization to increase the knowledge and understanding of its members regarding audition, Audiology, and rehabilitation of the hearing-impaired.

BRINGING UNITY TO AN INDUSTRY

Beltone Electronics Corporation recently embarked on a program aimed at bringing together all facets of the hearing health care field.

In 1981, Beltone President Lawrence N. Posen announced that Beltone had begun a search for the most outstanding professor of audiology in the United States and Canada. Beltone planned to honor that instructor with national recognition as well as a cash prize and a scholarship for a graduate student at the winner's university.

Posen's daughter, Laura, directed the program. She placed ads in national trade journals, various student newspapers and educational publications. Posters were sent to schools, along with letters urging the deans and department chairmen to help in this search. Nominations, however, would be accepted only from students.

Eleven Judges Chosen

Next, a panel of judges was chosen including a number of researchers, scholars and audiologists.

Students who responded to the publicity were sent a nominating package which included a form on which they were to tell why their instructor is the most deserving recipient of the Beltone Distinguished Teaching Award in Audiology, as it was named.

Nominations came from 22 states. Fifty-six teachers were nominated, most of them by more than one student. Some of the reasons cited were:

"His teaching methods are innovative, utilizing any and all available references to focus the student's understanding toward a particular system. He is extremely well informed and presents his students with state-of-the-art research. He is totally available to his students as a guide and as a caring instructor."

"His foremost concern as a professor is the intellectual growth of his students. His teaching responsibilities always take precedence over administrative duties and research interests. His lectures are consistently well organized and understandable and his examinations are well conceived and challenging."

"He encourages support rather than competition among the graduate students in audiology."

"His enthusiasm and interest in the subject of audiology is overwhelming and contagious. The depth of his knowledge of the subject is amazing. His terrific desire for students to understand and learn all material completely is reciprocated by students' desire to learn."

In addition to recommendations from students, deans, department chairmen and the usual list of vita and publications, the judges of the Beltone Teaching Award competition required nominees to submit a 400-600 word essay on "The Importance of Teaching to the Future Development of Audiology." The judges met in Chicago for two days, reading the essays and nominating forms and debating the merits of each nominee.

The winner that first year was Dr. Zahrl G. Schoeny of the University of Virginia. Schoeny was then invited to serve as a judge for the following year's competition.

Some very slight changes were made as the program entered its second year. A second and third place award were added, as was a student representative to the council of judges. The rest of the program remained intact, attracting nominations of 24 instructors the second year. The second year winner, as announced at the annual convention of the American Auditory Society November 17, was Dr. Terry L. Wiley of the University of Wisconsin at Madison. Tying for second place were Dr. Jay W. Sanders, Vanderbilt University School of Medicine and Dr. Frederick N. Martin of the University of Texas at Austin.

In the essay Dr. Wiley wrote for the Beltone teaching award competition, he addressed the problem of the "information gap," the disparity that exists today between published scientific evidence and clinical practice. He stressed the importance of people in practice sharing ideas and findings with the professional community, systematically recording both ideas and observations on which to base future research and ideas.

"The future of audiology as a profession," Dr. Wiley wrote,

"depends on close communication between scientists, clinicians and teachers."

Mr. Posen presented Dr. Wiley \$1,000, a plaque and a \$1,000 scholarship for a student at his school. The student who nominated him received \$100. Beltone will hold a banquet in Dr. Wiley's honor at the University of Wisconsin early in 1984.

"Selecting a winner this year was extremely difficult," Mr. Posen told the American Auditory Society gathering. "In fact, once the judges narrowed the competition to three finalists, they wondered if it was even possible to select one over the other two. They did, in fact, ultimately select a winner, but they declared a tie for second place."

Dr. Sanders and Dr. Martin, the runners-up, each received \$750, engraved bronze plaques and \$1,000 scholarships for students in their universities' audiology departments. The students who nominated them received \$100.

The chairmen of the Vanderbilt Department of Audiology, Dr. Fred H. Bess, wrote that Dr. Sanders "motivates students to search, inquire and go beyond what is given in class."

Beltone Proud of Program

Beltone's management has expressed considerable pleasure, in fact, amazement, with the outpouring of support the company has received in response to the Beltone Distinguished Teaching Award in Audiology program. Mr. Posen considers this association with the professional community a vital link to continued growth and success for helping the hearing impaired public.

In its first two years, the Beltone Teaching Award has already made inroads into familiarizing educators, researchers and students with the hearing aid side of the industry. It is an effort that Beltone plans to continue, interacting closely with all hearing disciplines.

The search for the 1984 Beltone Distinguished Teaching Award in Audiology will begin in February. Anyone wishing more information should contact Joan Siegel, Manager, Beltone Professional Relations, Beltone Electronics Corporation, 4201 West Victoria Street, Chicago, Illinois 60646, or call (312) 583-3600.

1983 BELTONE DISTINGUISHED AUDIOLOGY TEACHER JUDGING PANEL

(front row) LAURA POSEN, BELTONE PROJECT COORDINATOR; ARNOLD SMALL, PhD, UNIVERSITY OF IOWA; MARY E. KAWELL, UNIVERSITY OF ILLINOIS; DAVID J. LILLY, PhD, GOOD SAMARITAN HOSPITAL; JUDY A. RASSI, M.A., NORTH-WESTERN UNIVERSITY; DAVID M. LIPSCOMB, PhD, UNIVERSITY OF TENNESSEE. (back row) DON WORTHINGTON, PhD, BOYS TOWN; LAZLO STEIN, PhD, MICHAEL REESE MEDICAL CENTER; DAVID P. GOLDSTEIN, PhD, PURDUE UNIVERSITY; ZAHRL G. SCHOENY, PhD, UNIVERSITY OF VIRGINIA; ROSS ROESER, PhD, CALLIER CENTER FOR COMMUNICATIVE DISORDERS; BRUCE WEBER, PhD, DUKE UNIVERSITY.

A full day of discussion and debate took place among the judges at Beltone headquarters in Chicago.

Dr. Sanders tied for 2nd place in the 1983 Beltone Distinguished Teaching Award in Audiology.

Dr. Martin tied for 2nd place in the 1983 Beltone Distinguished Teaching Award in Audiology.

Dr. Wiley, winner of the 1983 Beltone Distinguished Teaching Award in Audiology.

Spring/Summer 1984

Audiology Congress and AAS to Meet in Santa Barbara August 26th

The 17th International Congress of Audiology convenes on the campus of the University of California, Santa Barbara, on August 26th, 1984. This is a significant event for the auditory sciences in North America because this congress has met in the U.S. only once before, in Dallas in 1970. It should be noted that the International Congress of Audiology is the only international meeting dealing with the subject of audiology in the most general sense. This 17th Congress, which is the biennial meeting of the International Society of Audiology, incorporates the 1984 meeting of the American Auditory Society. All aspects of the hearing sciences are contained within this four day meeting.

The Congress will have four plenary Round Table sessions. These are: (1) Etiology and prevention of hearing loss, chaired by Dr. Gisle Djupesland of Norway; (2) Audiology in developing countries, chaired by Dr. Tore Lundborg of Sweden; (3) Morphology and physiology of cochlear hair cells, chaired by Dr. Ake Flock of Sweden; (4) Psychoacoustics of the cochlear implant, chaired by Sanford E. Gerber of the U.S. Dr. Gerber is the president of the 17th Congress chosen by the general assembly of the International Society of Audiology at its 16th Congress held in Helsinki, Finland in May of 1982. In addition to the four plenary Round Table sessions, the organizing committee is preparing three special contributed sessions: one on standardization of the criteria for the auditory brain stem response, a second on middle ear implanted hearing aids, and a third on microcomputer electroacoustic analysis of hearing aids. Contributed papers dealing with the areas of audiology will be presented each afternoon.

The members of the organizing committee, in addition to Dr. Gerber, are: Jeffrey L. Danhauer, Ph.D., Vice President; Monica C. Goller, M.A., 2nd Vice President; Jorge A. Schwartzman, M.D., Vice President for Latin America; Maurice I. Mendel, Ph.D., Secretary General; and Gregory S. Keller, M.D., Medical Liaison. The organizing committee hopes that a large number of colleagues from Spanish speaking countries, notably Mexico and in South America, will participate in this congress. Consequently, the organizing committee has arranged for simultaneous translation into Spanish of the plenary sessions and the business meeting of the International Society of Audiology. Furthermore, each Round Table session has a Spanish speaking secretary: they are Dr. Jorge Schwartzman of Argentina, Dr. Jose Barajas of Spain, Dr. Luis Benitez of Mexico, and Dr. Pedro Berruecos of Mexico.

The venue for the 17th Congress is the campus of the University of California at Santa Barbara. Of course, many readers of Corti's Organ have visited UCSB in the past, and are aware of the beautiful site and the excellent accommodations. Santa

Barbara, as many of our readers know, is the "Riviera of the Pacific" and the university campus is located on the ocean shores. Registration is \$200 with accompanying persons paying \$25. Student registration is \$100. Housing will be provided at an extraordinarily low cost in university dormitories. The flat fee per person in a double occupancy room is \$300 for the entire congress, and that includes all meals incorporating the official banquet of the society and the welcoming fiesta. Considering the quantity and quality of the food, and the festive atmosphere, one can hardly stay home for that small sum. Advanced registrations for the congress as well as for housing are due by July 1, but the organizing committee will continue to accept them after that date. It is difficult and expensive to obtain hotel and motel accommodations in Santa Barbara, especially at that time of year; hence, those wishing such accommodations, really need to arrange for them instantly.

This will be the American Auditory Society's only meeting in 1984. It is the society's distinct pleasure to participate in the meeting of the International Society of Audiology and to consider its biennial congress our meeting. We will sponsor, as usual, the Carhart Memorial Lecture during the International Congress of Audiology. This lecture will occur on Tuesday evening, August 28, and our lecturer will be the distinguished Swedish scientist, Dr. Gunnar Liden. We will also have our Executive Committee Meeting during the course of the International Congress. The American Auditory Society urges all of its members to attend the 17th ICA at its 1984 meeting on Sunday afternoon.

New Telecommunications Devices Aid Hearing Impaired

A remarkable variety of new telecommunication devices make it easier than ever to communicate electronically with hearing-impaired people — whether they're right around the corner or as distant as New York or San Francisco.

Telecommunication devices for the deaf (TDDs) grow in popularity daily. A TDD lets a hearing-impaired person communicate directly, without the need for an interpreter. Both people need to have a TDD. Instead of speaking, they simply type their conversation from one machine to another. Here's a brief summary of how TDDs can help hearing-impaired people. This information was adapted from *Telephone Training for the Deaf* by Dr. Diane L. Castle (publisher: Alexander Graham Bell Association for the Deaf, Washington, D.C.).

Selecting a TDD

Choosing the right TDD depends on a person's needs; how they'll use the unit and where they'll use it. For example, if the deaf person has vision problems, a TDD with large, clear print is preferable. If space is limited in a home or office, a small TDD that is quiet may be better. Before buying a TDD, it's best to try out different models.

TDDs can be portable, semi-portable, or stationary, depending upon a person's needs, and can cost from \$150 to \$1,000 depending upon a person's needs, and can cost from \$150 to \$1,000. Some have a paper printout, and other have paper on a one line screen.

More information about TDDs is available from other deaf TDD users and Telecommunications for the Deaf, Inc. (TDI), 814 Thayer Ave., Silver Spring, Md. 20910. TDI is a non-profit organization with regional representatives to inform hearing or hearing-impaired persons about different TDDs and couplers and how to get them. Also, TDI publishes a special telephone directory listing phone numbers of TDD users in the United States and overseas.

A new, six-page brochure, "What You Should Know About TDDs," talks about new trends in TDDs, such as voice output, touch-tone signals, telephone lamp-flashers, and printers. It also contains a list of suppliers who can provide more complete product information. For a free copy write: Public Information Office, National Technical Institute for the Deaf, One Lomb Memorial Drive, P.O. Box 9887, Rochester, N.Y. 14623.

1984 AAS MEMBERSHIP DIRECTORY BEGINS ON PG. 3

PLEASE NOTE!

Due to mailing delays, the IAC/AAS meeting notice was delayed. Registration will be accepted until July 1st without a late fee. For further information contact Sandy Gerber, Ph.D., Speech & Hearing Center, University of California, Santa Barbara, California 93106.

Ear and Hearing Changing Hands

After five years as Editor-In-Chief, Ross Roeser is turning over his command to fellow AAS member Robert W. Keith. The AAS executive board approved the decision at its Executive Committee Meeting last November and the change will be effective with Volume VI.

Ear and Hearing, as we are all aware, has evolved into a premier professional journal in our field, and all those involved expect nothing but continued growth and success in the years to come.

Thanks, Ross, for a job well done and welcome aboard to Bob Keith.

Contributors should now submit their papers to Bob for future editions.

Gallaudet President Resigns

Washington D.C. — Jane Bassett Spilman, chairman of the Board of Trustees of Gallaudet College announced today that at its January meeting the Board accepted the resignation of Dr. W. Lloyd Johns, fifth president of Gallaudet, effective January 20, 1984. Dr. Johns became Gallaudet's president officially in October of this past year following the presidency of Dr. Edward C. Merrill, Jr. Dr. Johns came to Gallaudet College from California State University at Sacramento where he served as president for five years. He has resigned for personal reasons, and the Board extended its wishes to him for success and happiness in his future endeavors.

Dr. Jerry C. Lee, vice president for business and administration at Gallaudet, has been named interim president. He will be assisted by a management review committee established by the Board of Trustees. The Board is initiating the search process to recruit and select Gallaudet's sixth president. The search committee will begin its work February.

Dr. Lee began his career at Gallaudet 13 years ago. Before that time he served as vice president for administration for the Commercial Credit Industrial Corporation. He received his doctorate from the Virginia Polytechnic Institute and State University and attended law school in Maryland. He is widely published in the area of administrative law and holds the rank of associate professor with Gallaudet's Collegiate Faculty. He has requested that he not be considered a candidate for the presidency, and the Board intends to honor this request.

Gallaudet College, located in our nation's capitol, is a multi-purpose educational institution service deaf people through educational programs, public service, and research. Since it was established by Act of Congress in 1864, it has grown and changed to meet the needs of succeeding generations of individuals with hearing impairments. What has not changed is Gallaudet's commitment to its mission to serve the deaf children, youth, and adults of this nation, to help bridge the gap between hearing the deaf people, and to be a resource on deafness to other educators from around the world.

CORTI'S ORGAN is a publication of the American Auditory Society, processed in Dallas, Texas.

For further information, contact: Dept. of Otolaryngology, Children's Hospital of Pittsburgh, 125 De Soto St., Pgh., Pa. 15213 (412) 647-5466.

Letter to the Editor

Dear Editor:

This is in response to the article in Corti's Organ regarding hearing loss due to cordless phones. I am a member of The American Auditory Society and work for an otolaryngologist as a clinical audiologist.

We currently have two patients who claim hearing loss from loud sudden noises from cordless phones.

The first is a lady who was exposed to a loud blast from a Uniden, model EX 3000 B cordless phone to her left ear on July 15, 1983. Immediately following this exposure she complained of vertigo and tinnitus and hearing loss in the left ear. We initially saw her on July 18, 1983. This lady is employed as an executive secretary and this hearing loss has created communication problems in her occupation. She has been fitted with an in-the-ear hearing aid in the left ear which helps but she still experiences difficulty particularly trying to have phone conversations. The greatest presumed threshold shift is centered around 100 Hz.

The second case is a lady who was exposed to a loud blast from Midland cordless phone on January 10, 1984, to her left ear. Immediately following this exposure she complained of hearing loss in the left ear and later of tinnitus in the left ear. She has no record of hearing evaluations prior to the blast. Again, the greatest presumed threshold shifts are centered around 1000 and 2000 Hz. The lady also complains that there are effects on her career due to reduced communication skills related to the hearing loss.

I am terribly concerned that this information get to the public at large. One method to do this I feel is to inform professionals such as those belonging to the American Auditory Society so they can counsel their clients. In my opinion, people in particular who should be counselled regarding possible dangers to hearing from cordless phones are ones with an existing unilateral hearing loss who use the phone with the better ear; people who have children who may use the phone; and any other people who have an existing hearing loss.

I hope this is useful information.

Sincerely,

Elizabeth A. Van Dyke M.S.C.C.-A.
Clinical Audiologist

Editorial reply: Many thanks to Ms. Van Dyke for sharing this important information with us. If our readers are aware of additional incidents of hearing loss following use of the cordless phones please feel free to share them with us and/or contact Dr. Jerome Goldstein, AAO-HNS executive vice president at 1101 Vermont Ave., N.W., Suite 302, Washington, D.C. 20005.

PUBLICATION ANNOUNCEMENT

AUTHORS: Eugene C. Sheeley and Doris McQuiddy

TITLE: Steps Toward Effective Production of Speech (STEPS)

DESCRIPTION: A set of seven softbound booklets printed in large type. They are intended for the parents of children who have hearing and vision impairments. The booklets provide information about hearing loss, vision loss, where to find help, diagnosis, treatment, education, hearing aids, vision aids, etc.

PAGES: 323

SIZE: 8 1/4" X 5 1/4"

ILLUSTRATIONS: 112 line drawings

DATES: Booklet 1 — 1979, Booklet 2 — 1981, Booklet 3 — 1982, Booklets 4 and 5 — 1983, Booklets 6 and 7 — 1984

COST: A single set is free from the publisher.

PUBLISHER: Southeast Regional Center for Deaf-Blind Children
P.O. Box 698
Talladega, AL 35160

SPECIAL FEATURES

These booklets on hearing and vision loss can be used by parents with low reading levels, parents whose second language is English, parents who need large print aides and subprofessionals

Five hundred hearing and vision terms are defined in Booklets 2 and 3, creating the largest such glossary written for laymen.

The booklets are not copyrighted to encourage wider use.

Button Cell Ingestion Risk Increases

The Hearing Industries Association (HIA) has alerted all those serving hearing aid users to the increasing incidence of button cell ingestion, especially accidental ingestion of hearing aid batteries. According to statistics being compiled by the National Capital Poison Center, the vast majority of ingested button cells will pass through a person with no difficulty but some cases of batteries that have become lodged are being reported.

Become fully aware of some of the practical steps which can be taken in preventing hearing aid battery ingestion. Some of those steps are:

- Including warning copy on batter packaging directed towards keeping batteries away from children.
- Keeping batteries out of children's reach and discarding the batteries carefully.
- Not allowing children to play with batteries.
- Not changing hearing aid batteries in front of children.
- Never putting batteries in mouth for any reason as they are slippery and easily swallowed accidentally.
- Always checking medication before swallowing them as adults have swallowed batteries that were mistaken for tablets.

•Alerting users of hearing aids and parents of children who use hearing aids of preventive measures in handling batteries and hearing aids containing batteries.

•Disseminating the telephone number of the National Button Battery Ingestion Hotline, 202-625-3333. The Center will give immediate counsel in the treatment of individuals who accidentally ingest hearing aid batteries.

•Considering the possibility of altering the battery drawer to secure it from casual access by children.

The growth in sales of smaller types of aids increases the number of smaller, easy-to-ingest batteries in circulation. With proper preventative measures followed by all elements of the hearing health industry, the diminishment of the ingestion problem can be achieved.

INTER-NOISE 83 Proceedings Available

INTER-NOISE 83, the twelfth International Conference on Noise Control Engineering was held in Edinburgh, Scotland on July 13-15, 1983. The Conference was sponsored by the International Institute of Noise Control Engineering. It was organized by the Institute of Acoustics of the United Kingdom in cooperation with the Fellowship of Engineering.

A total of 294 papers on all aspects of noise control engineering were presented at the Conference and are included in the Conference Proceedings.

A two-volume set of Conference Proceedings is now available for immediate shipment. Edited by R. Lawrence, the INTER-NOISE 83 Proceedings reflects the theme of the Conference: Noise Control: The International Scene. The two volumes contain 1,242 pages of technical material.

Copies of the INTER-NOISE 83 Proceedings are available from Noise Control Foundation, P.O. Box 3469, Arlington Branch, Poughkeepsie, NY 12603, U.S.A.

17th INTERNATIONAL CONGRESS OF AUDIOLOGY

AUGUST 26-30, 1984

AT THE
UNIVERSITY OF CALIFORNIA
SANTA BARBARA

TOPICS OF THE ROUND TABLES

- (1) International cooperation and audiology in developing countries (Moderator: T. Lundborg)
- (2) Prevention and etiology of hearing impairment (Moderator: G. Djupesland)
- (3) Cochlear hair cell morphology and physiology (Moderator: A. Flock)
- (4) Psychoacoustics of the cochlear implant (Moderator: S. Gerber)

Hearing Health Team Trains for...

6th Annual Run for Better Hearing

Nineteen hearing help providers—representing the interdisciplinary support that made BHI the hearing field's most effective public educational program—will run in the sixth annual "Run for Better Hearing."

The Run is a fund-raising effort to strengthen BHI's hearing help message, already granted free media exposure worth over \$81 million in commercial time and space. BHI's program includes famous Americans who overcame hearing loss—Art Carney, Norm Crosby, Phyllis Diller, Nanette Fabray, Lou Ferrigno, Lorne Greene, Florence Henderson, Bob Hope, Frankie Valli, Keenan Wynn, and many others!

1984's Run doubleheader features BHI executive director Joe Rizzo in his fifth Boston Marathon on April 16. Then on June 16, in Duluth, MN, Joe will be joined in Grandma's Marathon by:

Duncan Clifton, L.T.I., Burlington ONT; Barbara Friedman, MA, Kathryn Jacklin MA, Becky and Mike Paparella M.D., All Univ. of Minn., Mpls, MN; Robert Hanrahan, Dispenser, Wilmington, DE; George Hicks M.D., Indpls, IN; Ron Hoff, Maico, Mpls., MN; Mead Killion Ph.D., Elk Grove, IL; William Lederer, American Hearing Research Foundation, Joan Osborne, wife of George Osborne Ph.D., Grace Touhy, friend of Joan, All Chicago, IL; Gunnar Liden M.D., Univ. of Gothenberg, Sweden; Arnie Monk, Dispenser, Winnipeg, Manitoba; Sharon and Ross Roeser Ph.D., Dallas, TX; Wayne Whitney, Dispenser, Eau Claire, WI.

BHI COMMITTEE & SUPPORTS

Run Steering Committee: Al Bruce, Bob Tischbein, Starkey Labs; Karen Turner, Jane Hixson, Dahlberg; Bud Raas, Earmold Design and Jean Broenen Activair, Supported by Karen Crammer, Hearing Instruments and Bill Mahon, Hearing Journal.

17th ICA Preliminary Program

(Specific sessions may be added or rearranged as needed)

SUNDAY, AUGUST 26, 1984

Check-In 12:00 - 5:00

Dinner: 5:00 - 7:00

Opening Ceremony & Reception: 7:30

MONDAY, AUGUST 27, 1984

Breakfast at 7:00-8:00

Round Table at 9:00

Prevention and Etiology of Hearing Impairment

Chair: G. Djupesland (Norway)

Secy.: J.J. Barajas P. (Spain)

Speakers:

A. Axelsson (Sweden)

F. Catlin (USA)

G. Mencher (Canada)

R. Ruben (USA)

R. Tomanek (Czech.)

Lunch at 12:00

Special Session at 1:45-3:15

Middle Ear Implants

Chairs: N. Yanagihara (Japan)

J. Danhauer (USA)

Speakers: K. Gyo (Japan)

K. Kodera (Japan)

H. Aritomo (Japan)

S. Hiki (Japan)

Contributed Papers at 1:45

International Audiology

B.C. Novaes & M.C. Bevilacqua; USA

The Practice of Audiology through the University in Brazil

P. Plath; West Germany

International Cooperation in Europe in the Fields of Audiology and Phoniatrics

R. Levinson; USA

A Survey of Hearing Aid Needs in the Caribbean

P.N. Nguma; Tanzania

State of Audiology in Tanzania

S. Nikam; India

Some Aspects of Audiology in India

A. Luts; USSR

Audiology and Rehabilitation in Estonia SSR

S.O. Olaniyan & J.M.A. Oyiborhoro; USA

Audiological Services in Nigeria

L. Sarkady; Kuwait

The Development of Audiology in Kuwait

V.A. Shah & M.N. Vyasamurthy; India

Research Contribution in the Field of Audiology in India

J.A.K. Barghouthi & L. Tieri; Italy

Audiological Cooperation Between Italy and Jordan

I. Silverman; USA

Audiologic and Other Services in Fiji

Aural Rehabilitation and Amplification

N.C.A. Chari; USA

Behavioral Comparisons of Canal vs. All in the Ear Aids

J.L. Danhauer & R.N. Kasten & C.E. Johnson & J.A.

Brimacombe; USA

The "Hearing Aid Effect"

A.D. Teigland & W. Wilson; USA

Backward Masking of Lip Postures

C.E. Johnson; USA

Validation of the Enhancement of Suprasegmental Parameters through Filtering

H. Ono, H. Ogawa, T. Deguchi, H. Nakahara, S. Sinohara & T. Okazaki; Japan

Development of the Lip Reading Display System for Severely Hearing Impaired Patients

O. Perier, A. Bochner, B. Everaerts & J. Michiels; Belgium

The Combination of Cued Speech and Signed French to Improve Spoken Language Acquisition by Young Deaf Children

T. Rahko, M. Karjalainen, T. Honkanen, M. Lindgren, A. Poivaara & P. Karma; Finland

Concept Learning and Self-Teaching System for Deaf Children

R.H. Hull; USA

Current Procedures in Aural Rehabilitation for the Older Adult

R.M. Parker; USA

Hearing Aid Candidacy in Children with Minimal, Fluctuating and/or Unilateral Hearing Impairments

Y. Onchi; Japan

A Fitting Test for Hearing Aids

S. Bornstein, R. Seewald & K. Randolph; USA

Hearing Aid Microphone Location, Binaural Listening, and Message Azimuth

G.F. Haas; USA

Compression Hearing Aids: Technical & Clinical Considerations

D.A. Preves; USA

Acoustic Feedback Rejection in Hearing Aid Fittings

L.M. Moser & J. Hellbruck; Germany

The Functional Gain of Hearing Aids Measured with a Psychoacoustical Loudness Scaling Test

C.L. Gammel; USA

Hearing Aid Fitting and Training for Very Young Profoundly Deaf Children

Auditory Physiology

R.J. Marchbanks & A.M. Martin; England

Assessing Abnormalities of the Cochlear Perilymphatic Pressure Using a Tympanic Membrane Volume Displacement Measurement Technique

S. Takashima, K. Osamu & K. Kanagawa; Japan

Pathological Changes in the Cochlea of Heritable Hyperlipidemic Rabbits

T. Inamori, H. Wakutani & T. Kumoi; Japan

Newly Designed Electrocochleogram's Parameters of SP Area in Meniere's Disease

T. Tanahashi, T. Hattori & M. Mori; Japan

Physiological Investigations on Tinnitus

J.H. ten Kate & P.M. van der Meer; Netherlands

Narrow Band AP to Click and Sine Bursts in Relation to 8th Nerve Response in Cat

J.H. ten Kate & M.F. van Bakkum; Netherlands

Rate vs. Time Coding in Spikes from 8th Nerve of Cat to Cosine Noise

R.S. Ackley, I.K. Arenberg & T.J. Balkany; USA

Electrocochleographic & Histopathologic Observation of Experimental Perilymphatic Fistula in Guinea Pigs

O.L. Nilsson, S. Rydmarker, D.E. Dunn & J. Grenner; Sweden

Noise-Induced Hearing Threshold Shift and Scanning Electron Microscopic Changes in the Inner Ear

K. Tsuzuki & N. Suga; USA

Complex-Sound Processing by Combination-Sensitive Neurons with Level-Tolerant Frequency Tuning

Break at 3:15-3:30

Psychoacoustics

A.T. Cacace & R.H. Margolis; York, USA

Loudness Summation and Critical Bandwidth

M. Suto, Y. Kato & S. Eguchi; Japan

Difference Limens for the Formant Frequencies: Comparative Study of the Value between Several Nations

F. Gradori; Italy

Pitch of Multicomponent Inharmonic Tones

K. Schorn & E. Swicker; West Germany

The Effect of an Additional Masker on the Frequency Selectivity of the Inner Ear

A. Quaranta & G. Cervellera; Italy

Brief Tone Audiometry and its Relation to Critical Band

C. Cave; France

Measurement of Temporal Acuity: Correlation between Detection and Double-Click Threshold in Normal-H Subjects

Pedaudiology

N.J. Johnsen, P. Bagi, J. Parbo & C. Elberling; Denmark
Evoked Acoustic Emissions from the Human Ear. Results in 100 Neonates

M. Ditoë & Y. Koike; Japan

The Risk Factors Related to Hearing Impairment Screening with the Crib-o-Gram

J.S. Johnson; USA

Early Identification/Intervention Programs: Cross-Cultural Perspective

H. Sugawara, H. Imai, S. Ogura, K. Asano, M. Okamoto, Yamamoto & S. Takano; Japan

The Follow-Up System for High Risk Registered Infant Crib-o-Gram Screening Tests

T. Kawakami, K. Asano, H. Akamatsu, K. Yamamoto; Japan

The Neurological Prognosis of the Babies who Failed Audiological Screening by Method of the Crib-o-Gram

W. J. Keith; New Zealand

A National Strategy for the Early Detection of Prelingual Deafness

H. Shimizu & M.C. Erskine; USA

Etiology of Prelinguistic Hearing Loss: A Retrospective Study

E.J. Kreul, R. Sandlin & J.C. Nixon; USA

Reliability of Simplified Method of Infant Hearing Screening

Cocktail Party & Mexican Fiesta at 6:00

TUESDAY, AUGUST 28, 1984

Breakfast at 7:00-8:30

Round Table at 9:00

Cochlear Hair Cell Morphology and Physiology

Chair: A. Flock (Sweden)

Secy.: L. Benítez (Mexico)

Speakers:

P. Dallas (USA)

A. Hudspeth (USA)

W. Brownell (USA)

Special Session at 1:45 - 3:15

Microprocessor electroacoustic Measurements

Chair: S. Hiki (Japan)

Contributed Papers at 1:45

Middle Ear and Impedance

F.J. Simmons, H.J. Greenberg & T.L. Sahley; USA
LDL Prediction Using Various Types of Acoustic Reflex Eliciting Stimuli

D.J. Lilly & R.A. Fishman; USA

Clinical Evaluation of Two Updated Tuning-Fork Tests

B. Moore (UK)

General Assembly at 11:30

Lunch at 1:00

Check-Out at 2:00

The Executive Committee of the American Auditory Society has announced the availability of Life Membership in our organization.

Eligibility requirements include membership status for ten consecutive years and an age of seventy years or more (we won't tell!)

For further information contact: Ross Roeser, Ph.D., Secretary/Treasurer AAS, 1966 Inwood Rd., Dallas, TX 75235.

Vol. 9 No. 3

Fall 1984

1984 Joint AAS/IAC Meeting A Success

Scenic Santa Barbara, California was the setting for the 17th International Congress of Audiology/American Auditory Society joint meetings. Referred to as "The Riviera of the Pacific," the history and beauty of the area was enjoyed by all in between meetings and a busy social calendar.

Upon arrival at the University of California at Santa Barbara, members and guests were greeted by the organizing committee and its very helpful staff. It was "back to college" for most members as housing was in the college dormitory in addition to several area hotels. Somewhat spartan, although very comfortable, Anacapa Residence Hall was home for over 540 conference attendees. Many new international friendships were initiated over the week — several during the long trek to the nearest "facilities" down the hill! Meals were served in a commons area and you can be certain more than one diet fell into ruin due to the abundant and well prepared meals. The courteous UCSB students were always ready to direct wayward souls to the proper food line, to clear away unwanted trays and to answer the countless questions posed to them by all in attendance.

Map in hand, it was off to participate in numerous round table discussions, scientific meetings and to view manufacturer's exhibits around the campus. The American Auditory Society's new display made its debut at the Congress as well. (See related story in this issue). Most of the larger for-

ums and the Carhart Memorial Lecture were held in the Lehmann Concert Hall. The setting was appropriate for the large number of participants who gathered to share current information on Cochlear Implants, Audiology in Developing Countries, Etiology and Prevention of Hearing Loss, and Cochlear Hair Cell Morphology. Distinguished speaker, Dr. Gunnar Liden, whose presentation may be read in its entirety in this issue of *Corti's Organ*, paid tribute to the late Dr. Raymond Carhart in his wonderful address entitled "Trends in Amplification for the Hearing Impaired."

The days and evenings in Santa Barbara that were not filled by attending lectures and professional meetings were occupied by other enjoyable activities. A Welcome Party, Mexican Fiesta (complete with mariachi band) and a Congress Dinner were times for socializing, getting to know new friends from around the world, and sharing international song, story, drink and dance. More than a few people were seen sneaking in a brisk swim in the ever-changing tides (despite the tar spots from a past oil spill), or taking a peaceful walk along the oceanfront.

The American Auditory Society wishes to extend its thanks to all members and our associates in the International Congress of Audiology, for the support of meetings such as this one and the opportunity for each of us to further our knowledge through the sharing of ideas. See you in Atlanta next year!

Call For Nominations

The American Auditory Society announces its call for nominations for the AAS Executive Board. The individual nominated should be willing to serve on various committees, attend the annual meeting and be interested in fostering the activities and direction of the American Auditory Society. Nominations should be sent to LaVonne Bergstrom at: Division of Head and Neck Surgery, Rm. 32-34 Rehab. UCLA, 1000 Veteran Avenue, Los Angeles, CA 90024. Deadline for nomination is November 1, 1984.

Ear and Hearing Awards Reinstated

At the 1984 AAS Executive Board Meeting, one topic of discussion was the reinstatement of the Ear and Hearing Editorial Award for outstanding papers submitted during the publication year. After several opinions were expressed for and against the granting of the awards, the Board voted to reinstate the award effective with the 1985 annual meeting. One goal of presentation is to continue to foster and support the presentation of quality writing submitted to Ear and Hearing.

AAS Display Unveiled

The 1984 AAS/IAC joint meeting in Santa Barbara was the scene for the unveiling of the new American Auditory Society Display Booth. Construction was overseen by 1985 AAS President Don Worthington who expressed his appreciation to his staff for their assistance in this project. The tri-fold display was built to increase word-of-mouth activity about AAS at various meetings and functions around the country. It features both advantages of membership and publication in a portable, attractive manner. The display is certain to encourage additional membership into our organization. Thanks Don for a job well done!

Coming Attractions

DAVID LIPSCOMB

David Lipscomb, 1985 AAS Meeting Program Chairman has announced the preliminary program for the joint AAS/AAO national meeting to be held in October, 1985 in Atlanta, Georgia. The theme for the meeting is "Technical Innovations in Clinical Hearing Science." Contributed papers should relate to the theme, emphasizing applications of our burgeoning technology.

For the first time, there will be a half-day workshop during the meeting leaving one half day for contributed papers. The title of the workshop is Auditory Electrostimulation Applications. Audimax has agreed to sponsor the workshop and will provide several of the participating speakers. Included in the slate at this time is Dr. Juergen Tonndorf, Dr. Jerry Northern and Dr. Robert Goldstein. We are indebted to Mr. Irwin Klar for his generous support of this program.

Watch for further details about the 1985 American Auditory Society Meeting in coming issues of *Corti's Organ*.

Carhart Memorial Lecture Trends in Amplification for the Hearing-Impaired

By Gunnar Liden, M.D., Ph.D., Professor
Department of Otolaryngology, University of Gothenburg
Gothenburg, Sweden
and
Visiting Professor
Department of Otolaryngology
University of Minnesota
Minneapolis, Minnesota

First of all, I want to thank the American Auditory Society for its generosity in selecting me to deliver the Carhart Memorial Lecture. I appreciate this very much and I am glad to be able, in this auditorium, to honor the memory of Dr. Raymond Carhart, who has had a major influence on the development of the science of audiology.

I think it is appropriate to remind you of some of the highlights of his career. He was born in 1912 and died in 1975 at the age of 63 years. Raymond Carhart went to Northwestern University in 1932, barely 20 years old, as a hopeful graduate student. He took his M.A. and Ph.D., majoring in speech pathology, experimental phonetics, and psychology.

In 1936, at the age of 24, he joined the faculty of Northwestern University as an Instructor in the School of Speech, where he worked hard. For the next 40 years he was a contributing member of the faculty. In 1947 he made his most important contribution to audiology by successfully establishing the first academic program in audiology in the United States as well as in the world. The bridge to the medical field was built when he became a Professor of Otolaryngology in

CORTI'S CALENDAR

October 26-28, 1984

AUDIOLOGICAL RESOURCE ASSOCIATION FALL MEETING, Roan Mountain State Park, Roan Mountain, Tennessee. Topics: "Speech Audiometry: Past, Present and Future," William Rintleman, Ph.D., "Computers in the Audiology Practice". Contact Fay Churhill, Suite 402, 2022 Brookwood Medical Center Drive, Birmingham, Alabama 35209.

December 5-9, 1984

The Departments of Otolaryngology and Pediatrics, University of Pittsburgh School of Medicine present **The Eleventh Annual Symposium EAR, NOSE AND THROAT DISEASES IN CHILDREN: A 1984 UPDATE** to be held at The Breakers, Palm Beach, Florida. For further information contact: Dept. of Otolaryngology, Children's Hospital of Pittsburgh, 125 DeSoto St., Pittsburgh, PA 15213. (412) 647-5466.

January 4-6, 1985

WESTERN SECTIONAL MEETING — American Laryngological, Rhinological, and Otolological (Triological Society), Santa Barbara, California. Sponsored by the Triological Society, to be held at the Marriott Biltmore in Santa Barbara. For further information contact: Joseph DiBartolomeo, M.D., Secretary, 2420 Castillo Street, Santa Barbara, CA 93105.

January 7-8, 1985

"THE ROLE OF IMMUNITY IN DIAGNOSTIC AUDIOLOGY: STATE OF THE ART." Marymount Manhattan College, New York, NY. Contact Carol A. Silverman at (212) 472-3800, ext. 576 for further information.

February 3-7, 1984

MIDWINTER MEETING OF THE ASSOCIATION FOR RESEARCH IN OTOLARYNGOLOGY at Surfside Holiday Inn Clearwater Beach Hotel, Florida. For further information contact: W.A. Yost, ARO, Parmlly Hearing Institute, Loyola University, 6525 North Sheridan Road, Chicago, IL 60626.

February 10-13, 1985

SECOND INTERNATIONAL FORUM ON ASSISTIVE DEVICES FOR HEARING IMPAIRED PERSONS, Fort Lauderdale, Florida. For Preregistration information and a copy of the preliminary program write to: Fellendorf Associates, Inc., P.O. Box 32227 Washington, D.C. 20007.

February 22-24, 1985

AUDIOLOGICAL RESOURCE ASSOCIATION WINTER MEETING, Gatlinburg Tennessee. Contact Faye Churchill, Suite 402, 2022 Brookwood Medical Center Drive, Birmingham, Alabama 35209.

March 10-16, 1985

The 19th **COLORADO OTOTOLOGY-AUDIOLOGY WORKSHOP** will be held at the Continental Inn and Aspen Conference Center in Aspen Colorado. For further information contact Jerry Northern, Ph.D., Colorado Hearing Foundation, Box B210, 4200 E. 9th Avenue, Denver, CO 80262.

April 4, 1985

CONTINUING CARE OF THE HIGH-RISK INFANT, Park Ridge, Illinois. Sponsored by Ross Laboratories and the Department of Pediatrics, Section of Neonatology, Lutheran General Hospital. Guest faculty include: Marshall Klaus, M.D., Michigan State University, and David Caldarelli, M.D., Rush Medical College of Rush University. Additional information contact: Mary Lou Mumford, Newborn ICU Office, Lutheran Medical Hospital, 1775 West Dempster Street, Park Ridge, IL 60068. (312) 696-5313.

May 26-31, 1985

XIII WORLD CONGRESS OF OTORHINOLARYNGOLOGY, Miami Beach, Florida, USA. For further information contact: Anthony J. Maniglia, M.D., FACS 1500 N.W. 12 Avenue, Suite 874, Miami, FL 33136. (305) 325-8899.

Letter to the Editor

Dear Editor:

I read with interest your previous article and "Letter to the Editor" from Ms. Van Dyke about hearing loss caused by cordless phones.

I am an attorney who handles product liability cases and have several cordless telephone cases. In fact, I have what will probably be the first case to go to trial in the country. In this case, the plaintiff is an M.D. and the defendant is the Uniden Corporation. My brother, Daniel Schumaier of Johnson City, Tennessee, and Daniel Orchik of the Shea Clinic, both Ph.D. Audiologists, tested the suspect telephone at the Audiotone Laboratory in Phoenix. Both the ring and page tones were in excess of 140 dB.

There is simply no reason for such a loud dB level or for the location of the ringer to be in the earpiece. The product is unquestionably defective and unreasonably dangerous.

Manufacturers and distributors of this \$600 million plus a year industry which was fueled by the AT&T divestiture jumped into the market place without adequate design engineering. When these products were found to cause injury, band-aid surgery in the form of warnings were issued rather than adequate measures such as product recall and design changes. The warnings placed by these manufacturers and distributors are inadequate and ineffective. They are there less to warn than to attempt to disclaim liability in this unreasonably defective product.

Changes in industry come only through legislation or financial messages. Perhaps significant liability judgments around the United States will persuade these manufacturers to relocate the ringing device to a place on the back of the handset and render the device safer. This cost to relocate the ringer is only \$1-\$3. The cost to each human being in the form of decreased hearing and tinnitus is incalculable. The people who have not yet been injured could possibly be warned by the subscribers to your publication. Those who have already been injured should seek legal redress from a qualified trial attorney. The maybe the industry will listen.

Yours very truly,
Steven G. Schumaier
Taylor, Schumaier & Sluggett
Attorneys at Law

Brochure Available

A cochlear implant system that can provide a sense of hearing to profoundly deaf people is described in a new brochure available from Otologic Products/3M.

The brochure gives a brief introduction to the cochlear implant and explains how it can help a damaged ear hear sounds. In addition, the brochure tells who is most likely to benefit from using the device and outlines the elements of a typical cochlear implant program.

A discussion of both the benefits and the limitations of the cochlear implant is included.

For a free copy of the brochure, write: Otologic Products/3M, Department SU84-106, Box 33600, St. Paul, Minnesota 55133.

This brochure, which describes cochlear implants, is available free from 3M.

NOW AVAILABLE THROUGH AAS
A full length videotape of the 1984 Carhart Memorial Lecture presented by Gunnar Liden, M.D., Ph.D. at the 1984 IAC/AAS Joint Meeting is now available on a loan basis. For availability and reservation please contact Ross Roeser, 1966 Inwood Road, Dallas, TX 75235.

Audiological Resource

Association Fall Meeting

The fall meeting of the Audiological Resource Association will be held at Roan Mountain State Park, Roan Mountain, Tennessee, on October 26-28, 1984. An excellent program is planned in two areas of special interest to all audiologists. The first topic is "Speech Audiometry: Past, Present and Future" and will be presented by William Rintleman, Ph.D., Professor, University of Pennsylvania School of Medicine.

Many feel speech audiometry is a test area that is often misunderstood, misinterpreted, and under-utilized. Dr. Rintleman's presentation will help clinicians develop a fuller appreciation for the diagnostic potential of speech audiometry.

The second topic will be "Computers in the Audiology Practice: More Thoughts". Gene Bailey, Ph.D., Professor of Computer Science, East Tennessee State University will discuss a number of topics important for an understanding of computers and their applications in today's business world. Both this presentation and the final one are a continuation of the winter meeting and reflect the organization's recognition of the ever growing role computers play in today's society.

Larry Hutto, M.A., Audiological Resources, Inc. will discuss the application of computers to the audiology practice. His lecture will deal with the many ways computers can be useful to an audiologist and he will give special attention to the use of computers in industrial testing.

The meeting site is a rustic mountain setting with individual cabins and many hiking trails. It is expected that the mountains will be made more beautiful by the fall colors which are expected to be near their peak at that time.

Registration will be open to all interested individuals. Further information may be obtained from the ARA Secretary, Ms. Faye Churchill, Suite 402, 2022 Brookwood Medical Center Drive, Birmingham, Alabama 35209.

Immittance Workshop Announced

A two-day workshop titled "The Role of Immittance in Diagnostic Audiology: State-of-the-Art" will be given January 7-8, 1985 at Marymount Manhattan College in New York City. The featured speakers are Dr. Shlomo Silman and Dr. Stanley A. Gelfand. Dr. Shlomo Silman is Associate Professor of Audiology, Brooklyn College, Brooklyn, New York. Dr. Stanley A. Gelfand is Chief, Audiology and Speech Pathology Service, Veterans Administration Medical Center, East Orange, New Jersey. Both speakers are authors of numerous publications on acoustic immittance. The topics include: immittance theory and concepts; calibration of immittance devices; measurement of the temporal parameters of immittance devices and the time course of the acoustic reflex; quantification of acoustic-reflex magnitude; probe-frequency effects in tympanometry; prediction of hearing loss with the acoustic reflex; effects of pathology, hearing loss, and age on the acoustic reflex; monitoring of acoustic-reflex artifacts; discussion of case studies and review of problem cases from the audience. In addition to lectures and discussions, demonstration of procedures will be provided and immittance devices will be on display. The tuition is \$175 (\$115 for full-time students) until December 1, 1984. After December 1, 1984, the tuition is \$190 (\$130 for full-time students). There is an extra charge of \$6 if ASHA CEUs are requested. One lunch and coffee breaks are included in the tuition fee. Substantial handouts will also be provided. The workshop is sponsored by the Communication and Learning Center, Marymount Manhattan College, 221 East 71 Street, New York, N.Y. 10021. The workshop is co-sponsored by Guinta Associates, Inc., 67 Leuning Street, S. Hackensack, N.J. 07606. Questions should be directed to the contact person: Carol A. Silverman, Ph.D., Program Director (212-472-3800 ext. 576). Marymount Manhattan College is approved by the American Speech-Language-Hearing Association to sponsor continuing education in speech-language pathology and audiology. The above activity is offered for 1.4 CEUs in partial fulfillment of the requirements for the Award for Continuing Education.

Patent Obtained

Associated Hearing Instruments of Upper Darby, Pa. announced that E. Robert Libby has been issued United States Design Patent No. 247,839 on July 24, 1984 for the design and development of the "Libby Horn". The Libby Horn is based on Mead Killion's original research on the 8CR and 6EF type earmold constructions. Most earmold laboratories throughout the world utilize the "Libby Horn" in order to obtain a smooth, wideband transparent hearing aid response. Libby also received the prestigious Fletcher Award from the "New York League for the Hard of Hearing" for the development of the horn.

ARO In Its Second Decade

For over a decade (since 1973) the Association for Research in Otolaryngology (ARO) has provided a forum for research in all areas of otolaryngology. Its membership has grown to almost 600 researchers with approximately 400 participants attending its annual Midwinter science meetings.

The ARO was an outgrowth of the Committee for Research in Otolaryngology of the Old American Academy of Ophthalmology and Otolaryngology (AAOO), now the American Academy of Otolaryngology — Head and Neck Surgery (AAO-HNS). For the seventeen years prior to 1973 the Research Committee provided the major focus for research with AAOO. In 1973 the demand for research led to the formation of a new society, ARO, which held its first fall meeting in Palm Beach, Florida in 1974. Although ARO is now an independent society, it still maintains close ties with AAO-HNS primarily in the joint sponsorship of the Research Forum held each year at the annual meetings of AAO-HNS (this year's meetings were in Las Vegas with the Research Forum taking place on September 15).

ARO, thus, sponsors its annual Midwinter Meeting (at Clearwater Beach, Florida, February 2-7, 1985), co-sponsors the Research Forum at the annual meeting of AAO-HNS, and publishes four Newsletters each year along with the abstracts of papers presented at the Midwinter and Research Forum meetings. The Midwinter Meeting is usually a combination of special topic symposia-workshops and contributed papers covering all aspects of basic and applied research in otolaryngology. The ARO recognizes an outstanding scien-

tist(s) as its Achievement of Merit Winner at each Midwestern Meeting.

Membership categories of Active, Associate, Corresponding, Honorary and Senior members include 287 Ph.D.s, 244 MDs, and 26 joint MD-Ph.D. degrees. Members are from 46 states and 21 foreign countries. The membership has been growing at the rate of approximately 10 percent a year.

The present officers of the society are: President: William Stebbins, Ph.D.; President-Elect: Robert Ruben, MD; Past-President: Maxwell Abramson, M.D.; Secretary-Treasurer: William Yost, Ph.D.; Historian-Editor: David Lim, M.D.; and Council members: Bobby Alford, M.D.; Donald Nielsen, Ph.D.; and Murray Sachs, Ph.D.

The 1985 Midwinter Meeting will feature four symposia-workshops: Comparative Hearing, Comparative Reception of Complex Stimuli, Auditory Perception of Complex Non-Speech Stimuli, by Humans, and Inner Ear: Morphology and Physiology.

Additional information about ARO, membership applications or information about the Midwinter Meeting can be obtained from the ARO Secretary-Treasurer, William Yost, (312-508-2710), Parmlly Hearing Institute, Loyola University of Chicago, 6525 North Sheridan Road, Chicago, IL 60626.

Berlin Announced

As '84 BDTAA Winner

CHARLES I. BERLIN

Charles I. Berlin, Ph.D., director of the Kresge Hearing Research Laboratory of the South Louisiana State University Medical Center (LSUMC) in New Orleans has been named the winner of the 1984 Beltone Distinguished Teaching Award in Audiology (BDTAA).

The BDTAA is the only teaching award bestowed in the field of audiology. To be eligible, instructors must be nominated by a current or former student and have five or more years of experience in teaching audiology.

The result of this year's search was announced by Joan Siegel, M.D., Beltone manager of professional relations, on August 29 at the International Congress of Audiology in Santa Barbara, CA.

In making the presentation, Siegel noted Berlin's outstanding reputation among students, audiologists, doctors and laypersons as a teacher, lecturer and researcher. She illustrated his commitment to the future of audiology by quoting from his required essay, "From Student to Practicing Audiologist."

Berlin's essay, adapted from a "family recipe" of his father's, the late Dr. Sol Berlin, ended with this advice: "When the product is finally finished (some aging is almost always useful), take the audiologist back into the hot academic ancestral kitchen and teach him how to 'bake' even better than you did. Each generation has an obligation to produce better offspring than the one that preceded it."

Berlin has taught advanced clinical audiology to medical and audiological students for 25 years. He is especially well known for the educational materials he has designed and his work in ultra-audiometrics. He is the founder of Kam's Fund, a national organization for the study and management of ultra-high frequency hearing loss. Berlin is a frequent lecturer and author, with almost 250 verbal presentations and 150 written presentations to his credit. Among the many other honors he has received, the most recent is the 1983 Louis DiCarlo Award for outstanding clinical contributions from the Louisiana Speech and Hearing Association.

Francis Shipley-Brown, a former student of the Berlin's, is currently pursuing her doctorate in audiology at the University of Maryland. In her essay, she summarized why Berlin is held in such high regard: "He is acknowledged by his colleagues and his own former teachers as a man who makes the most difficult ideas clear. Whenever his name is on a program, I make a point of attending his lectures; he consistently teaches us new things in a kindly, lucid and supportive fashion."

Berlin was chosen from a field of 21 candidates. His essay was one of seven factors weighed by a blue-ribbon panel of judges. The panel was composed of 10 prominent professionals in the field of audiology — including the two previous BDTAA winners — plus one student representative chosen by NHSSLA.

The judges were Dr. Fred Bess, Vanderbilt University; Dr. Bradley Edgerton, House Ear Institute; Dr. Jack Katz, State University of New York; Dr. Bob Keith, University of Cincinnati; Brian Lee (student) University of Montana; Dr. Geary McCandless, University of Utah; Dr. Ross Roser, University of Texas Callier Center; Dr. Zahrl Schoeny (1982 winner), University of Virginia; Dr. Bruce Weber, Duke University Medical Center; Dr. Terry Wiley (1983 winner), University of Wisconsin; and Dr. Don Worthington, Boys-town Institute.

Membership Addressed

During the 1983 Executive Meeting of the American Auditory Society, the board members approved Ross Roeser's recommendation that I assume the position of Editor in Chief of *Ear and Hearing*. Recently, Suzanne Brown wrote and asked if I would like to submit an "Editor's Address" to *Corti's Organ*. Her request provided me with an opportunity of sharing some thoughts with AAS members as I begin my duties as editor.

Many of you know that the journal *Ear and Hearing* evolved from *The Journal of the American Auditory Society* that began in 1975. The first editor-in-chief was J. Donald Harris, followed by Ross J. Roeser. Under their direction and with the help of a large group of section editors and referees, the journal has grown in stature and has become an important source of scientific and clinical information. It is an honor to follow Don and Ross as editor of this fine journal. I deeply appreciate the support of the Executive Committee and the members of the American Auditory Society.

As editor, I have only one goal — and that is to continue the level of excellence for which the journal is already known. There will be a few minor surface changes, some sections will be renamed and some new section editors will be announced in the first issue of 1985. There will not be any fundamental changes in the philosophy of the journal, however, and we will continue to publish basic and applied research that relates to the clinical interests of our readers.

As members of the American Auditory Society and potential contributors of *Ear and Hearing*, you can help in a number of ways. If you have ideas and suggestions that might help the journal, we would like to hear from you. If you are interested in serving as a peer reviewer, let us know, and provide us with information about your special area of expertise. If you have an interesting manuscript that is appropriate for the journal, send it for review. And finally, if you talk with your colleagues, let them know about the journal and invite them to join the society. You should be aware that increased membership provides, among other things, additional support for the journal.

I would like to thank those of you who have written with expressions of support and good wishes. I would also like to congratulate Suzanne Brown of her appointment as Editor of *Corti's Organ*, and to urge your support of her work. Together the new editors of the two publications of the American Auditory Society may be remembered for "boldly splitting infinitives that have never been split before" (Hitchhiker's Guide to the Galaxy, p. 114), so we will appreciate all the support and help from the members that we can get.

Robert W. Keith, Ph.D.
Mail Location 528
University of Cincinnati Medical Center
Cincinnati, Ohio 45267

Continued from page 1

the Medical School as well as a Professor of Audiology in the School of Speech at Northwestern University.

Carhart's impact on the community of scholars can be measured in a variety of ways. He was a superb teacher. His ability to clarify the most complex issues was recognized and appreciated by all his students. He personally guided 45 students through successful doctoral and post-doctoral study. He had a unique insight into human behavior and he was a warm and compassionate human being. This combination allowed him to instill a sense of confidence and self-worth not only in those who successfully completed their programs, but in all of his students.

Carhart exerted a significant influence on the development of his field. He held chairmanships, trusteeships, and consultantships in dozens of organizations at the local, state, and national levels. In 1963, he became the only member of his profession to receive a Research Career Award from the National Institutes of Health. Dr. Carhart's era of greatness was mainly spent in the University barn. As a visitor, I was impressed that so much exceptional work could come out of those plain quarters. However, he finally moved into new facilities worthy of his qualifications.

My personal contact with Ray Carhart started in 1950 in Stockholm, where he served as a highly appreciated lecturer at the First International Course in Audiology. This course was in fact the impetus for the birth of audiology in Europe. During recurrent visits I got an opportunity to get acquainted with his research. Throughout his career, he was concerned with basic problems of psychoacoustics including such issues as forward and backward masking, masking level differences, binaural fusion, and lateralization. Nevertheless, his major contribution to his field resulted from the attention he gave to problems relating to clinical audiology. If any aspect of Carhart's research efforts can be singled out as representative of his significant contributions, it is his work relating to the refinements in interpreting the pure-tone audiogram. He detected individual deviations from expected patterns of response which led him to systematic explorations of the phenomena. "Carhart's notch" is an example of this.

When Ray had a difficult and tiring scientific problem, he loved to draw himself back to his Shangri-La, where he recuperated by alternately writing papers, or fishing. Carhart's contributions to the evolution and refinement of speech audiometry and the application of this tool to the assessment of the efficiency of hearing aid performance in the individual patient are widely recognized. From his scientific audiological will, published as an introduction to the textbook **Amplification for the Hearing Impaired** by Michael C. Pollack, it is evident that he wanted clinical audiology to develop faster and to live up to his expectations. Unfortunately he never did get to witness the enormous revitalization of research on his favorite topic, the selection of hearing aids. In order to pay homage to his memory, I have chosen to spend the rest of this lecture in talking about current trends in amplification techniques.

In an overview of the history of methods of selection of hearing aids, Studebaker points out that three distinct periods can be recognized: before, during, and following Carhart's era. As all of you are aware, his procedure for evaluating hearing aids was principally based on the methods of speech audiometry. Emphasis was especially given to sensitivity, limits of tolerance, performance in noise, and discriminative efficiency. Besides Carhart's comparative and more flexible methods, the Harvard Report and MedResCo Study dominated for a long time with their recommendations that a single frequency-gain characteristic would provide the optimum amplification for most hearing-impaired subjects.

In the mid-seventies, the role of selective amplification regained popularity. One main reason for the increase in nonverbal methods of selection of hearing aids compared to the conventional Carhart method was that speech tests do not differentiate between differences in performance of hearing aids. However, new methods in the testing of speech seem very promising for the selection of hearing aids. According to Hagerman, determination of a threshold value of the signal-to-noise ratio for synthetic sentences in speech-noise at 50 percent intelligibility has proven to differentiate between different hearing aids. His performance/intensity function has a very steep slope of 25% dB.

The term "prescriptive selective amplification" means that the frequency response of the hearing aid is tailored to conform with the patient's individual needs. The goal is to achieve the highest possible intelligibility of speech as well as good listening comfort, in order to make speech comfort-

tably audible. The optimal placement of speech energy within the patient's auditory area has to be determined. To accomplish this goal, the physical dimensions of the gain-frequency response curve and the saturation sound pressure level (SSPL) or maximum power output (MPO) of the hearing aid must be in concert with the thresholds and comfortable and uncomfortable levels of the patient.

Many different methods of prescriptive selection have been developed in order to find the optimum amplification or the best frequency response. One well recognized method uses the tone threshold or the threshold for one-third octave band noise for describing the gains that are needed across the spectrum. Lyberger introduced the half-gain rule and proposed using an amount of gain in each frequency region equal to about half of the hearing loss. The threshold levels can also be inserted into formulas that take into account the spectrum of speech. They base their recommendations on predictions derived from the relationship between hearing level and preferred gain at each frequency. Berger et al. have used similar methods.

Another popular method bases the desired gain-frequency response curve on the subject's Comfortable Loudness Contour, and the difference between this contour and a normal subject's auditory threshold or comfortable level. These methods differ in many details but common to most of them is that the prescribed frequency selective amplifications should be verified by some sort of real ear measurements. It is a well known fact that the frequency response curve of a hearing aid measured in a coupler or ear simulator will be altered by different types of molds and horn couplings and does not give a very reliable picture of the sound pattern in front of the eardrum. A more realistic assessment of the real ear frequency gain is obtained with psychoacoustic measurement of the functional gain, i.e. the difference between unaided and aided thresholds. Liden and Kankkunen used it as an indispensable method for selection of hearing aids for children.

There seems to be some uncertainty about what shape of functional gain produces the highest discrimination scores. According to Pascoe, a uniform hearing level gives satisfactory help for subjects with moderately severe hearing loss. There is, however, a risk of using functional gain because it can lead to the use of too much gain in hopes that lower thresholds will give better results. Measurements of insertion-gain obtained with an ear-canal microphone or with a soft probe/tube microphonic system have gained in popularity and are excellent for real ear measurements. This technique simplifies the fitting of the hearing aid.

Hearing aid technology and fitting techniques can today offer most patients satisfactory intelligibility and listening comfort. In noisy situations, comprehension of speech may be improved by selective amplifications of high frequencies, at the price of somewhat less comfortable listening. In quieter environments, the high frequency gain may be decreased without lowering comprehension of speech but with improvement in listening comfort. So far, these two competing desires in listening have had to be met with two different types of hearing aids, just as many people have a separate pair of prescriptive sunglasses.

In an interdisciplinary research project between Chalmers Technical University and our Department of Audiology at Sahlgren's Hospital, Gothenburg, a wearable, programmable hearing aid with multi-channel compression has been devised. Basically, this aid has a memory built in by which different frequency response curves can be programmed from a computer. The signal-processing chosen for this wearable, programmable hearing aid is multi-channel compression using three channels with two programmable crossover frequencies. The compression threshold of the AGC circuits and the gain are programmable for each channel. The hearing aid is thus fitted to suit different types of hearing loss by way of a microcomputer based psychoacoustic measuring and fitting unit. This unit measures the equal-loudness contours of the subject at comfortable levels and calculates the differences between the equal-loudness contours of the hearing-impaired subject and the normal hearing person. Further, the parameters of the programmable hearing aid are calculable and the memory of the aid is programmed. By means of a probe-microphone or an ear-canal microphone, the real ear insertion gain is determined. The computer verifies whether the gain in frequency response obtained deviates from the gain desired.

... a computer-based system, elderly untrained users with moderate sensorineural loss preferred considerably less gain in everyday listening situations than had earlier been suggested. During the last decade we have witnessed new developments in the area of non-conventional hearing aids, such as middle ear implants, cochlear implants, and bone-

anchored hearing aids. I will dwell especially on the last mentioned topic and later describe it in some detail.

Non-Conventional Hearing Aids

Middle Ear Implants

There has been considerable interest in the last ten years in such non-conventional hearing aids as middle ear implants. Generally speaking, these consist of a motion-transducer which is partially or fully enclosed within the middle ear space. The transducer transmits energy (vibration) into the inner ear via the ossicular chain or via the cochlear capsule. A conventional, regular hearing aid amplifier may be used to drive the transducer.

One type of transducer has relied upon induced magnetic field effects. The induction devices use a small permanent magnet which is attached to the ossicular chain or the tympanic membrane. Electric current led to a small coil of wire placed close to the magnet produces an alternating magnetic field corresponding to the fluctuations of the sound. The alternating magnetic field causes the magnet to move in a pattern that mimics the input signal. According to Glatke, this type of transducer can transmit intelligible speech, but the efficiency of energy transfer is poor. Piezoelectric devices have also been implanted and have received considerable attention.

Cochlear Implants

The use of electrical auditory stimulation in the management of postlingual deafness has advanced considerably and is no longer looked upon as human experimentation. The information which can be conveyed by single-channel stimulation can assist the totally deaf to achieve partial rehabilitation. The cochlear implant can give release from the world of silence and help to identify important environmental sounds. It is recognized as an aid to lipreading and may help to improve the subject's intonation and articulation. A relief from tinnitus is also reported.

Progress toward restoration of intelligibility of speech has, however, been slow. Even if frequency were properly distributed in space and in time by means of multiple electrodes, a real improvement in the intelligibility of speech could not be expected. The reason lies in the lack of coding of the input in the cochlear nerve fibres, normally provided by the hair cells. Unless such coding can be provided, there is little chance that a signal will reach the right place in the higher processing centers where it can be interpreted.

Bone-Anchored Hearing Aids (BAHA)

A quite different and new approach for a special group of subjects with conductive or mixed hearing loss is the bone-anchored hearing aid. Although the objective of surgery or medical treatment for middle ear disease and conductive hearing loss is to get a dry ear with satisfactory hearing, we know that this goal cannot always be reached. Some patients are in need of a hearing aid but are unable to use a device that transmits the sound via the external ear canal. These patients may benefit from a conventional bone conduction hearing aid. The most conspicuous indications for such a device are:

- Chronic ear condition that drains or starts to drain if the ear canal gets obstructed.
- Malformations of the ear, absent ear canals, and extensive conductive dysfunctions which for some reason cannot be corrected by surgery.

However, a bone conduction hearing aid has many disadvantages:

1. The transducer must be applied with a constant force to the mastoid region with resultant discomfort, irritation, and sometimes exzema of the soft tissues.
2. The fixation of the bone vibrator is often unsatisfactory. When supplied via "hearing glasses," the function deteriorates with flaccidity of the frames.
3. The quality of the transmitted sound is generally poor.
4. The aesthetic appearance is not always cosmetically satisfactory.
5. Due to the relatively high signal velocity needed, the transducer and the electronic part of the aid must be kept apart to avoid acoustical feedback.

The present use of bone conduction hearing aids in Sweden is 140-1,000,000, which corresponds to about 3 per cent of all annual fittings. The actual need for bone conduction hearing aids might, however, be greater, were it not for the poor function of the conventional bone vibrator. Many patients do not use any aid at all or they prefer an ordinary aid even if the ear starts to drain when they use it. One way of improving the situation is to implant some sort of device directly into the temporal bone and to establish a permanent reaction-free penetration of the skin.

This idea has been implemented in the bone-anchored hearing aid. Due to the pioneering work by Branemark et al.

Continued to page 5

Continued from page 4

in Gothenburg on osseointegrated titanium implants, and by Tjellstrom et al. using this implant in the temporal bone, a new approach to wearing bone conduction hearing aids has been developed. The method is based on the idea of permanently anchoring a threaded cylindrical titanium screw (fixture) into the temporal bone and connecting an external hearing aid to the fixture by a titanium abutment penetrating the skin. The problems in accomplishing a direct bone-anchorage with a permanent and reaction-free penetration of the skin will first be discussed.

The soft tissues covering the skull dampen sound energy considerably. Arlinger and Kylen observed in their work on drill-generated noise levels during ear surgery that the acceleration levels of the temporal bone increased 10-25 dB when the transducer (minishaker) was in direct contact with the temporal bone, as compared to when intact soft tissues were covering it. This knowledge indicates that a direct contact between the hearing aid transducer and the bone might be of great value in bone-conducted transmission of sound. Many techniques for implantation of different metals into various bones of the body have been tried during the last ten years, but many have not been successful because of adverse side effects on tissue.

Osseointegration of an implant means direct contact between the implant and the living bone tissue. Many different opinions on the possibility of achieving and maintaining osseointegration have prevailed. According to Jacobs, osseointegration is only possible with coated metal implants or with ceramic implants. Branemark et al. used titanium for implants. The surface of titanium becomes instantaneously coated with an oxide layer when exposed to air. Because of this property, titanium as an implant material may be regarded as a ceramic, not a metal.

Although more knowledge has to be gained, there seems to be a chemical bonding between titanium and bone. Clinical experience of more than fifteen years has shown this technique of bone-anchorage to yield excellent long-term results. The method has also been used in treating edentulousness, but inserting titanium screw implants into the maxillary and mandibular bones. According to Branemark et al. and Adell et al., more than 3,000 dental implants have been inserted in about 400 patients with a 10-year success rate of more than 90 percent.

Osseointegrated titanium implants have been found capable of penetrating the skin without adverse reaction, provided that the free movement of the skin is restricted. The first titanium screw implant in the temporal bone was done in Gothenburg in 1977. Since then, 245 titanium fixtures have been inserted (June, 1984), partly for procuring a bone-anchored aid, partly for attaching an auricular prosthesis in patients suffering from malformations of the ear or with a missing pinna after tumor surgery or traumatic injuries. A five-year report by Tjellstrom et al. indicates that the titanium fixtures have remained stable and had no side effects from the skin-penetrating abutments.

The surgical procedures are generally performed under local anesthesia and consist of two stages described by Tjellstrom et al. During the first step, a series of drills is used to create a cylindrical bone defect which the is tapped. The fixture is then gently inserted into the bone. All preparations of the bone are done to assure minimal injury to the tissue. The titanium fixtures are osseointegrated and stable after about four months. Then, at the second surgical procedure, the skin-penetrating titanium abutments are attached to the implant.

Only two fixtures out of the 245 implants have failed to integrate with the bone. The first failure was found in a young girl with a hemifacial malformation. The thickness of the bone was only 1.5 mm where the implant was placed. The second failure was in a patient who had been treated with radiation due to a squamous cell carcinoma. However, four other implants in the same irradiated area did integrate without any problems. A fixture in a third patient had to be taken out because of psychological problems.

The first-generation bone-anchored hearing aids, used during the period 1977 to 1981 by 14 patients with conductive lesions, consisted of a conventional plastic-cased Oticon bone vibrator which was applied to the titanium fixture by means of a simple snap-connection. Due to impedance mismatch, this new direct bone conduction hearing aid suffered from troublesome resonances and distortion which resulted in displeased patients. Other common reasons for this dis-

pleasure were poor functioning of the mechanical connection and the unaesthetic arrangement. Moreover, the microphone and the transducer had to be kept apart to avoid acoustical feedback, and from this standpoint, no improvement had been achieved by this first generation bone-anchored aid.

Comprehensive measurements of mechanical impedance revealed that the magnitudes of mechanical impedance of the skin-penetrated human head are 10 to 39 dB higher than those of the skin-covered human head. This knowledge about impedance made it possible to develop a new bone-anchored hearing aid with all the parts in a single housing. During 1981, the prototype of this second-generation of bone-anchored hearing aids was successfully tested on one patient. At the end of 1981 it was decided that a sufficiently high level of safety had been reached, and a series was manufactured and fitted to ten of the 14 first-mentioned patients.

The result of evaluation of this group are reported. They investigated with Bekesy audiometry the difference in hearing thresholds among these ten subjects when an Oticon transducer (Oticon 10381-F 06-3) was applied a) rigidly to the titanium fixture, and b) conventionally, to the intact soft-tissues. The average improvement in the threshold in terms of electrical quantities fed to the transducer varied between approximately 10 and 20 dB in the frequency range of 600-6,000 Hz. The threshold shift was also measured in terms of mechanical quantities generated by the transducer in seven patients. The transducer was now rigidly attached to a miniature accelerometer (B & K 4344). The average lowering in acceleration thresholds when measured directly on the titanium screw as compared to when measured on the intact surface of the skin was found to be between 16 and 29 dB, with an average over all frequencies of 20.8 dB. The lowering of hearing thresholds means lower gain in the amplifier, lower consumption of power, and lower levels of distortion.

Another series of bone-anchored hearing aids was manufactured during 1983 and fitted to 15 subjects with conductive or mixed hearing losses. The evaluations of this group are only partly finished. The judgment is based on tests with newly developed lists of spoken sentences, edited in a computer, word by word, and presented in speech noise. The intelligibility curve has a maximum steepness of 25% dB at threshold. The patients' faculties for understanding speech in noise are graded by their threshold values of the speech-to-noise (S/N) ratio for 50% intelligibility (the speech level was held constant at 63 dBA). The threshold values can vary from -7 to +7 dB signal-to-noise ratio depending on hearing loss. Repeated measurements of S/N thresholds in speech noise showed a standard deviation of 0.4 dB for subjects with normal hearing and 0.71 dB to 1.1 dB for moderate to severe hearing-impaired subjects. Eight of the patients with pure conductive hearing loss showed an improvement of the signal-to-noise thresholds with, on the average, +5.6 dB. Among these individuals, the improvement ranged from -0.9 to 10.1 dB. The other seven patients had considerably pronounced mixed hearing loss. The S/N threshold improvement for all 15 patients was, on the average, +3.8 dB.

At this moment, no general rules can be given about the amount of superimposed sensorineural loss which can benefit from the bone-anchored hearing aid. However, the present study indicates that patients with mixed hearing loss and a bone conduction curve around 50 dB of hearing loss make good use of the bone-anchored hearing aid. All patients' subjective evaluations were very positive, indicating superiority of the new aid. The audiological indications for using a bone-anchored hearing aid can briefly be summarized as including:

1. Any patient who uses a conventional bone conducting hearing aid.
2. Any patient who uses air conduction hearing aids with a mold in spite of draining ears. These patients should use a conventional bone vibrator, but dislike it because of its disadvantages.
3. Any patient who needs amplification but conventional air conduction hearing aid cannot be used. Medically, these patients will be diagnosed as including those with: (a) congenital atresia in whom surgery is contra-indicated; (b) operated congenital atresia but draining ear if mold is used, or if satisfactory hearing has not been obtained; (c) chronic otitis media, operated or non-operated, with conductive and/or mixed hearing loss; (d) radical mastoidectomy and meatoplasty experiencing acoustic feedback when using air conduction hearing aid.

4. Amount of hearing loss: (a) air conduction levels up to a pure-tone average of 80 dB hearing loss (.5 to 2 kHz); (b) bone conduction levels up to a pure-tone average of 50 dB.

Contra-indications for using bone-anchored hearing aids include:

1. Subjects with mixed hearing loss in which bone conduc-

tion thresholds are greater than a pure-tone average of 50 dB hearing loss (.5 to 2 kHz).

2. Patients with pure sensorineural hearing loss.

3. Emotionally unstable or developmentally delayed patients.

4. Patients under the age of 16 years.

Choice of Ear for BAHA: The ear with the best bone conduction should be chosen. The present advantages of the bone-anchored hearing aid (BAHA) compared to conventional bone conduction aids can be summarized as:

- improved wearing comfort, because no static pressure on the skull is needed to transmit sound vibrations to the cochlea and no steel spring is needed to hold the transducer in place;
- improved aesthetic appearance, as the BAHA is available in a single case;
- improved quality of sound due to lower distortion;
- improved intelligibility of speech, especially in noise;
- reduced consumption of batteries.

The major steps forward in technical performance of the bone-anchored hearing aid have been taken, but improvement will be seen in the next generation of aids. The inconvenience of having the titanium screw implanted seems, at least to Sweden, to be surpassed by the advantages mentioned here for this new type of aid. Hopefully, the bone-anchored hearing aid will benefit a considerably larger group of the hearing-impaired than the conventional bone vibrator does. A multicentric study group recently established will try to accomplish this goal. The groups are located at the University of Minnesota, Minneapolis; Columbia University, New York; University of Texas, San Antonio; University of California, San Francisco; and the University of Gothenburg, Gothenburg, Sweden.

Looking back, we can state that Ray Carhart was a very demanding man, often blaming clinical audiologists for functioning primarily as consumers of research performed by others instead of being producers of it. He may have been right. On the other hand, I am certain that if Ray were alive today, he would have been pleased with the developments in selective amplification, programmable hearing aids, computerized fitting of hearing aids, middle ear and cochlear implants, and bone-anchored hearing aids. Somehow I have a feeling he is aware of these developments and is providing silent encouragements to many who continue to work in these and other challenging areas of research.

Notice: Stimulating News

Audimax, Inc. is proud to announce the availability of the Tonndorf Audiometer. This new instrument is named after Juergen Tonndorf, M.D., Professor of Otolaryngology emeritus, Columbia University, New York, in honor of his significant research accomplishments in the study of cochlear physiology, and mechanisms of auditory bone conduction and the application of electrostimulation for auditory diagnosis and therapy.

The Tonndorf Audiometer is a technologically advanced instrument that utilizes electrical stimuli to assess hearing sensitivity. It is a non acoustic audiometer that makes possible high frequency audiometric testing through 20,000 Hz, for direct cochlear assessment.

According to Irwin Klar, Vice President of Audimax, Inc., the Tonndorf Audiometer generates an audio signal to modulate a high frequency carrier (60 kHz). Combined signals are transmitted to the listener through a pair of externally applied electrodes. The striking result is the perception by the listener of extremely high-fidelity pure-tones and broad spectrum signals, ranging up through 20,000 Hz, without involvement of traditional acoustic transducers and with minimal influence of the outer and middle ear.

The Tonndorf Audiometer brings to both the clinician and the researcher new and important diagnostic capabilities for identification of cochlear pathology.

For more information, contact Mr. Irwin Klar, Vice President of Marketing, Audimax, Inc. (201) 448-4444.

DO WE HAVE YOUR CORRECT ADDRESS?

The Delivery of Information to Patients with Hearing Loss

By Frederick N. Martin, Ph.D.

As clinical audiologists we usually find ourselves, upon completion of a history and examination with a great deal of information regarding a patient's hearing. When we provide much of this information to patients or their families we are reinforced for what we say by words of appreciation. We have all heard phrases like "Nobody ever really explained this to me before, even though I have been tested many times," or "Of all the places we have taken our child no one has ever taken the time to try to make us understand what hearing loss is all about." These words of appreciation are so good for our egos that we find ourselves go into more and more detail, outdoing by great distances those "disinterested" clinicians whom the families may have encountered earlier. Who is to say whether we are burdening the family with test details that are beyond their comprehension and whether we enjoy our "jargon" because it makes us feel important.

Before proceeding I believe I owe it to the reader to be candid about the source of my keen interest in the subject at hand as well as my main outside information resources. More than a quarter of a century of dealing with patients in the counseling process, which I believe to be the most important aspect of the audiologist's responsibility, have led me to seriously question the methods we use in dealing with families of hearing-impaired persons. A dramatic personal experience, which I will relate shortly, brought much of this conjecture into sharp focus.

Many of the statements I will make come from the writings of those authors whose works are listed in the bibliography which accompanies this paper. The writings, especially of Luteran, Webster, Kubler-Ross and Stream and Stream, are essential reading for any clinician who will need to deliver "bad news" to another human being. I was recently a recipient of sudden bad news and speak of this with deep personal feeling.

About 4½ years before this writing, my son, who was 20 years old and about to graduate from college to enter medical school, noticed a sudden and dramatic change in his vision. What followed was a series of visits to specialists including ophthalmologists, optometrists, neurologists and specialists in internal medicine. They felt that indications were that this might be normal eyestrain associated with being a university senior. One ophthalmologist became furious at learning he was being seen for a second opinion and when we asked him to repeat the visual perimetry test he refused saying it was a waste of his time and our money. He further suggested that "neurotic behavior" on the part of the parents could create neurotic behavior on the part of the son that a six foot college senior "...does not need his daddy to take him to the doctor."

Audiologists have little training in the visual system, except for what they remember from courses in sensory psychology, but what we know about central auditory lesions makes us wonder when similar symptoms appear elsewhere in the sensory system. For this reason I persisted in finding a more complete diagnosis of my son's problem and finally located, through a colleague, a neuro-ophthalmologist in Dallas, about 200 miles north of our home in Austin, Texas. What followed there was the incident that has precipitated this paper.

After performing a brief physical examination and visual perimetry test in Dallas, my son was sent to radiology for some skull films. My fears of a central visual lesion became exacerbated at that time but I was fairly calm. When the x-rays were completed and we were standing in the hospital hallway the physicians came from the radiology department with the films in his hand. I asked what he thought the problem was, halfway expecting to be told it was nothing. What I was told rocked me to my very core. He said, and I use quotation marks because these are, to my best recollection, his very words, "David has a tumor pressing on his optic nerve. He needs immediate surgery or he will be blind in two weeks and dead in four." It is here that I learned what a crisis reaction really is, and no amount of reading or observation of families or patients could have taught me this lesson better.

That night we drove home to Austin where my wife flooded me with questions; all logical and important ones. Somewhere much of this information had been provided to me by the physician in Dallas, but I recalled none of it. I did not know the nature of the surgery, the probably type of tumor, the prognosis both for our son's recovery and for the return of his vision, the length of stay in the hospital, other side effects, etc. I was useless as a source of information. When the key words, "blind", "tumor", "dead" hit me I became incapable of processing any further information. I am cer-

tain in my own mind now that to some extent these are the events which occur when people are told words like "deaf."

I have found, both clinically and personally, that different people react differently to bad news depending on their personality makeup. Audiologists, of course, do not tell people that they or their loved ones are going to die. But to some people the irreversibility of their or their child's hearing loss impacts in much the same way as impending death. It is a situation which, at the time, they cannot handle. Some of the common stages people go through when dealing with bad news will follow, but first reactions usually involve shock, denial, anger or open confrontation as a main defense in the face of bad news.

Part of the assimilation of bad news includes at least some time in the grieving process, and time is essential to passing through this process. To rush it is to risk poor or no adjustment. Some people feel that if they cannot have their life the way they want it, with normal health, a normal child, normal hearing, then they don't want their life at all. The patient or parent may lose the desire to "go on." For many people who face what they believe to be catastrophic disorganization of their lives, guilt is the eventual result of anything that might even bring them a small amount of pleasure.

When adults enter the audiology clinic it is with the awareness that they have a hearing disorder. They often oversimplify it in their minds and expect an easy solution to their hearing problems. Being told that the loss is sensorineural and that the "treatment" involves a good deal of expense and effort on their part can be shocking and disappointing. However, they are better prepared for bad news, in most cases, than are the parents of small children who are being seen for what they have begun to feel may be a general communication disorder.

As Luteran points out, most parents do not consider hearing loss very seriously when they begin to wonder whether something is wrong with their child. This awareness usually occurs by the time the child is six months of age. When children do not do what their parents expect them to do in the way of development, the parents' first fear is of mental retardation, a fear that often does not leave them even after a completely different diagnosis has been made.

Often some considerable period of time is lost after one parent first suspects that something is wrong. The other parent's response may be that there is over concern. If they suspect that hearing loss is a possibility in their child's apparent lack of response to the environment, they may set off on a series of home-designed "hearing tests," which will, of course, lead to responses by the child which may be real, imagined, or provoked by stimuli other than auditory ones. Surely what will result is inconsistency.

When the parental concern for the child becomes mutual they may decide to seek a professional diagnosis. Often, however, one parent takes the child to a specialist without the knowledge or approval of the other. The professional seen first is usually a physician, often a pediatrician. Because physicians are accustomed to seeing parents who are "overanxious" about their children their initial response is frequently to try to comfort the parents and to put the best face on the child's problem. In addition, the physician's attempts at hearing testing will probably be no more sophisticated than those of the parents. The usual advice is to either forget about the possibility of a problem and that all is fine, or that children have to be older than the child seen before accurate tests can be carried out. "This 'waste of time' is often severely resented by parents and hearing-impaired children after a correct diagnosis is made.

Eventually the diagnosis of hearing impairment is determined. This is usually done by an audiologist and it is the audiologist who should convey the information to the parents. What happens in many situations is that an otolaryngologist receives the information from the audiologist, delivers the diagnosis to the parents who are then referred back to the audiologist for detailed counseling and recommendations for remediation. This is a most unfortunate process since the interruptions and the discontinuity add confusion to a complicated process of handling shocking and very bad news. What ensues is a series of reactions from the parents.

While experts may differ slightly in the precise terms they use to describe the various stages of reaction to bad news people experience, and even in the exact number of stages through which individuals may pass, there is general agreement on the progress of events. For example, after being told that their child has a severe hearing loss, according to Luteran parents go through five stages which are shock,

recognition, denial, acknowledgement and constructive action. These will be discussed now in order.

Shock is a response which separates the self from reality as a means of dealing with stress. While in a state of shock it is virtually impossible to process new information in any meaningful way. Heaping data, suggestions, plans of action and various strategies for dealing with situations which cannot be fully grasped may be less than a waste of time because individuals may realize their helplessness and be unable to do anything about it. Parents have told me that once the key words, such as "permanent hearing loss" have been heard what follows might just as well be in a foreign language. In some cases people come out of their shock rather quickly; in other cases it may take months or years.

The natural reaction to shock is a strong desire to flee; to get to what Luteran calls a "safe place." This safe place may be home, the company of a loved one, or into the personal automobile on the way home. Being totally unprepared for bad news and on "foreign ground" at the same time may be overwhelming and the individual may panic. Obviously description of the audiogram, results of other tests and designs for remediation cannot be understood under these conditions.

When the patient or family reach a "safe place," recognition of what has happened begins to occur. A curtain of disbelief begins to raise from around what is viewed as a terrible occurrence and the reality of what has been told there conceptualizes. At this juncture the emotions which have been suppressed come to the surface. At this point, patients describe the onset of grief which is experienced as much physically in some cases as emotionally. People describe a deep sense of pain in which the other mundane matters of their world fade instantly from importance. The car payment, the mortgage, the home and job difficulties which have been bothering them all seem silly and unimportant in the face of what seems a terrible loss. People are simply overwhelmed.

In the stage of recognition comes the realization that they are totally unprepared to deal with what must be dealt with in some cases, the rearrangement of social life and career; in other cases the rearing of a handicapped child. The feelings of inadequacy which may have been handled with some bravado in the past are exacerbated in the face of new and unusual circumstances. People look for someone to save them from this awful situation and, as Luteran points out, all too often there are audiologists or other clinicians who feel that they can step in to act as the saviors. Having someone else "take over" the situation may seem to the patient or parent the ideal thing to happen at this point but the actual result is more likely to be a deepening of a sense of inadequacy and the development of a dependent relationship on the professional. The patient or family may not mature to the point where they can handle the actions and decisions necessary to remediate the situation on a long-term basis.

An emotion which may develop at any time and which often really never leaves is anger. Part of the anger is self-directed since individuals feel that they should have known what was coming and been better prepared for it. Some of the anger may be directed at professionals who have "missed the diagnosis" and wasted what may be precious time in therapy. Some anger may be directed at people or situations which may have caused the problem, for example, each parent may actually feel a sense of hatred for the other when they are told that their child is "deaf" and feel that it must, in some way, be the other person's fault. Sometimes a repressed anger is felt towards the patient themselves. For an audiologist to attempt to dismiss this anger as silly and unproductive may seem logical but it is fruitless. As a matter of fact, audiologists may be the recipient of the anger for it is they, after all, who have dropped the bombshell of bad news.

Often clinicians attempt to jar the family to reality by placing responsibility on them. Kubler-Ross relates the story of a physician who got angry at a mother for crying when she was told that her daughter would soon die of leukemia. When she was told that she must get hold of herself for the child needed her strength, the mother felt her inadequacy to this task so deeply that she became confused and lost. At the other extreme is the clinician who offers to step in and solve all the family's problems. This action may seem generous and may even be welcomed but it increases parental or patient inadequacy and fosters a dependent relationship.

Continued to page

Continued from page 6

People are angered by situations over which they have no control. When their hopes for a miracle cure have been dashed, they direct their anger at those whom they feel may have held out false hopes. When they must make important decisions rapidly without being prepared for these decisions they become angry at having been rushed. The fact that hearing aids are less than perfect amplification devices and do not solve auditory deficiencies in a manner similar to the way eyeglasses solve visual problems may produce anger. When their lives and the lives of their families are altered in many ways, anger results. There is little that an audiologist can say to the angry parent of a small child who demand to know why they were previously told that their child was alright or that the difficulty would be outgrown.

Despite their anger, people sooner or later realize that it is they who are responsible for their lives or the well-being of their children. It is fine to be angry at someone else and to look for ways of placing blame for what they have or have not been told in the past. It is **guilt** which sets in somewhere around this time. People ask themselves what they may have done or not done to cause the situation and sense the guilt for not having acted sooner. Often the feelings of guilt are so deep that the situation cannot even be discussed. The illogical anger which the parents feel towards each other fosters the sense of guilt and deepens the sense of mourning.

Since dealing with the situation may be difficult, a simple way out is to deny that it exists. The notion may develop that a different clinician may give brighter news and so parent or patient may be going to shop for a rosier diagnosis or a system of dealing with the situation which is less demanding. All experienced clinicians have seen parents who virtually never stop shopping for a "better" diagnosis or a treatment that will result in a better "cure" for the deafness rather than do what must be done in terms of retraining. The **denial** may be short-lived or may last indefinitely.

What is to be desired is to help the family to the stage of acceptance of the problem. The individual may say "Well, I guess I'm going to have to get used to the idea that my hearing will not come back," or "If I'm going to get anything done for my child I might as well acknowledge that his deafness is permanent and get on with the purchase of a hearing aid and some language stimulation." These words may or may not reflect true acknowledgement of the situation that can result in positive actions. All-too-often people know the right words to say without really meaning them.

Luterman describes, as a stage which follows acknowledgement, a time for **constructive action**. At this point the individuals begin to take charge of the situation, accept their new status and set about to the tasks at hand. This is not to say that people do not return as situations change to earlier and less productive stages, but having reached the point where positive things begin to happen is surely a milestone.

It is important to realize that individuals do not work through these stages by themselves. For them to be able to develop the skills that they need to deal with their new lives requires the skills of a sensitive and strong clinician. Surely our patience and our support of the family do not pay off in every situation. We are often frustrated at what appear to be foolish and fruitless actions. Often we are excluded from the situation at a point where we feel we can do a great deal of good. We must resist the temptations to rush people out of stages which they are not ready to leave. We must develop in ourselves the warmth and nurturing we would expect from others if we needed it. We must show that we care by getting involved, but cannot assume responsibility for managing the lives of others who must learn to do this for themselves.

Some of the mistakes that audiologists make are inherent in their very training. We are taught many things to do and are shown how to do them well. When we engage in less than a great deal of activity, it seems to us we are not doing our jobs. Now, after all the technical tasks have been done in the way of diagnosis, we must wait and guide the recipients of our services in a sometimes painstaking way. Helping others to deal with their feelings so that they can sooner or later accomplish what we feel they must accomplish is tremendously demanding on us. We must be helpful without being condescending. We must be keenly interested without becoming emotionally involved. And we must do all of these

things for each case with a full caseload waiting for us. The demands on the audiologist are greater than we may have been prepared for in graduate school.

The audiologist-counselor seems to fail or succeed more on the bases of individual personality traits than on professional training. How does one teach another to be a warm and nurturing individual? The audiologist who is technically excellent may lack the compassion necessary to work with parents of deaf children. Professors and supervisors must look for these characteristics in their students but are limited in the career choices which they can impose on others.

The reader is directed specifically to the humanistic approach Richard and Kathryn Stream describe in the counseling of parents of hearing-impaired children. Such sensitivity is rarely seen in the audiological literature. They help us to realize that every person counts, that we all need help, that we must all take full charge of our own destinies and cope with difficult situations. We must learn to give information judiciously at times when families and patients can utilize the information, we must familiarize ourselves with systems of psychotherapy that can be beneficial to others, and we must learn when to make referrals when people need more help than we can provide.

Management Of The Hearing Impaired Child

Perspectives of a Physician-Parent

Thomas J. Fischer, M.D.
Childrens Hospital Medical Center
Cincinnati, Ohio

I would like to briefly comment on the problem of the hearing impaired child from the viewpoint of a physician (pediatrician) /parent of a hearing impaired child.

My almost 6-year-old daughter suffered a profound bilateral hearing loss at age 14 months during an episode of H-influenza meningitis. She had gone to bed one Sunday night to awaken on Monday with a low grade fever and ataxia. A neurological consultation followed by a lumbar puncture revealed only a couple of white blood cells in her spinal fluid. However, she appeared septic and was admitted and treated within four hours after she awoke ill. Her spinal fluid grew out H-influenza. Likewise, her hospital course was uneventful—no seizures, a few days of fever, and home in approximately 10 days. But my wife and I knew that something was not right, she didn't seem as responsive as the child we had known before. I checked her ears. Despite myringotomies in the hospital, I noted a reaccumulation of fluid. Antibiotics were immediately given and within a week ventilatory tubes were placed—and still she was not hearing. The days following now seem blurred, but audiometry followed by BSER were done without delay and the news was bad; our worst fears had been confirmed—Elizabeth was profoundly deaf.

The thunderbolts of a statement struck us hard and marked a significant change in the life of our family. This change is not static but dynamic, daily affecting us in an ongoing manner. The challenge of raising a deaf child is difficult, especially for the mother who is usually relegated the primary responsibility. Although difficult, we have sensed a growth in our personal lives, making us more aware of what really counts in life. And, as a physician, my eyes were opened.

Quite frankly, from my personal, non-professional contacts with parents of deaf children, it is unfortunately apparent that physicians are often unpopular with these individuals — often for good reasons. Commonly, pediatricians will be blamed for delays in diagnosis, having made unfortunate comments such as "Your child is too young to test."

The otolaryngologist will often make the diagnosis but in the perceptions of the parents, appear insensitive to their tragedy and unknowledgeable about habilitation options. If these perceptions are in fact accurate, the consequences for the child can be devastating, especially in the smaller community where the otolaryngologist is the hearing expert and logically in the layman's thinking should be the deafness expert. We are all acutely aware that in 1984 no physician alone can adequately meet the needs of the hearing impaired child. This physician needs help from the audiologist, educators, and social service agencies. However, that fact does not allow otolaryngologists to abdicate their pivotal roles in this story. What are my suggestions to help the otolaryngologist play a successful role?

Number one, be aware of the need for a team approach and, more importantly, find out in your community who will

While bad news about one's hearing or the hearing loss of one's child may be difficult to accept, it is the responsibility of the audiologist to assist the family in making the best possible adjustment so that steps toward habilitation or rehabilitation can be taken. To suppose that more exposure to facts can result in constructive action is often an error. Until people are brought to the point where they can properly process information, they cannot utilize either their own talents or the talents of the audiologists trying to help them. Hearing loss, like many maladies of humankind, can produce deep suffering, and we must work through this with our patients so that we can help to improve their lives.

be helpful members of the team, giving parents sensitive counseling and knowledgeable answers to their questions. Furthermore, communicate with these other professionals. Help smooth the way for the patient and parents. They will appreciate your help and sense a firm control and a caring approach.

Know your audiologist and expect and demand an audiological consultation completed within six weeks. In your locale establish contacts with reputable hearing aid dealers who have expertise in dealing with young children, can instruct parents on the uses and limitations of hearing aids, and can help the parent successfully implement an amplification program.

Secondly, the otolaryngologist can help support the efforts of parents in obtaining optimal educational opportunities. Although otolaryngologists are not expected to be authorities in deaf education, their knowledge of hearing and its tremendous role in language acquisition and psychosocial development, must make them aware of the tremendous demands required to educating a hearing impaired child — to educate them for a functional and psychologically satisfying role in our society. Be sophisticated and realize that the educational approach to the deaf child is not homogeneous but must be tailored to meet the needs and abilities of the individual child and not tailored to meet the educational philosophies of the education institution or professionals contained within.

Number three, be an activist! A physician's support of parents struggling to achieve optimal educational experience (especially in a small community) might be the necessary element from a respected member of the community to sway sluggish educators. Also, be aware that by public law 94.142 lack of funds to provide appropriate special education is not an acceptable excuse by local school officials.

Number four, realize that ongoing otologic care is mandatory and essential for optimal hearing aid use. From personal experience, I know that a serious otitis media can completely knock out any benefit from amplification of residual hearing. If this occurs in your patients, realize that they are cut off from the hearing world and please schedule them early and treat them aggressively. Along the same lines, residents in a training program should have the opportunity to meet and treat these children, to be aware of their problems, and to feel comfortable in their presence.

Private otolaryngologists, in addition to meeting medical needs as a part of ongoing care, should become involved with these institutions or schools who have a mission for deaf education and habilitations. Serving on a medical advisory board, promoting public education about these problems, and supporting fund raising activities are always appreciated and helpful.

Number five, for those otolaryngologists doing research on deafness, realize the tremendous potential and never forget the tremendous gift of hearing that someday can come out of your efforts. Keep on working despite the obstacles. However, be aware that unfounded and premature

Continued to page 8

RUN FOR FUN!
(SEE BACK PAGE)

Continued from page 7

public statements on advances can psychologically traumatize an already traumatized family and patient.

A sixth point is that as a counselor you should advise parents against trying to be the ultimate "perfect parents", mythological superhumans who donate 24 hours a day to the handicapped and leave no time for themselves or other family members. Suggest that shared experiences and support with other parents of hearing impaired children can foster more appropriate perspectives. A number of agencies both nationally and locally are available to help meet this need.

Finally, I have saved this point for last, not because it is less important but because it is the most important and I want you to take it home. Realize, especially in the early stages of learning about the diagnosis of deafness, what this diagnosis means to the parents. The wise physician knows that when the parents learn of this diagnosis in their child, that a part of the child has died — the bright dream for the future has been dimmed for them. At this time the emotions are mixed and varied: denial, anger at the apparent injustice of the situation, sadness, frustration, and depression. With this in mind, counsel the patient as a caring friend, truthfully and empathetically. Allow sufficient time in your schedule to listen and discuss this new diagnosis. Giving the diagnosis to parents and walking out is cruel, the empathetic physician realizes the intensity of the situation and is not uncomfortable or surprised if the mother and/or father cry. The empathetic physician listens and supports, truthfully admitting that he does not know everything, especially the future. The physician however, can truthfully state that the future of the child's life still can be satisfying despite the hearing loss, the child is still acceptable, still valued, and still loved.

Amplifon Chooses Winner

On March 21, Professor Nils Gunnar Henriksson of Lund University was awarded, at the Milan Press Club, the Amplifon Research and Studies Center International Prize for 1983.

This prize is awarded yearly to the international personality who has most contributed to the advancement of studies on deafness.

The 1983 edition of the prize was granted to Professor Henriksson by decision of the Italian, European and American Scientific Societies of Otorhinolaryngology and Audiology, and the board of Directors of the Amplifon Research and Studies Center.

Professor Henriksson is a pioneer in the field of vestibology, the medical branch which deals with the pathological disorders affecting the vestibular system and which may cause a loss of balance, visual disorders, tinnitus and deafness.

The prize was delivered to the Swedish scientist by A.C. Holland, President of CRS Amplifon.

To honor Professor Henriksson a Round Table on "New Techniques of Functional Analysis in the Field of Neurology" was held at the end of the ceremony and attended by a crowd of specialists from all over Italy.

Professor Boccardi (Director of the Physical Medicine and Rehabilitation Department of the S. Carlo Hospital, Milan), Professor Boeri (Scientific Director of the C. Besta Institute of Neurology, Milan), Professor Maffei (Director of the Laboratory of Neurophysiology, National Research Council, Pida), Professor Mira (Associated Professor of the ENT Clinic of the University of Pavia), Professor Pignataro (Associated Professor of the ENT Clinic of the University of Milan) were the lecturers: Professor Schmid (Director of

the Department of Computers and Systems Science of the University of Pavia) was the Round Table chairman.

The choice of the prize-winner and the prize-awarding ceremony itself focused everybody's attention on the state of the art of vestibology, a science which is going to play a more and more relevant role in the future.

How much this is true was proven by one of the last Shuttle space missions and the launching of Spacelab, the first European Space Laboratory, the research program of which comprised, amongst many other targets, the so-called "Science of Life," a wide project dedicated also to the study of the reciprocal influence between the vestibular system and the brain with the aim of discovering the causes of "space sickness."

The CRS International Prize (amounting to 7 million It. Liras) has been awarded for the past 13 years.

Previous winners were: Dr. Tokuro Suzuki, Dr. Erik Wedenberg, Professor Hallowell Davis, M.Me. Suzanne Borel Maisonny, Professor James Jerger, Professor Joseph J. Zwislocki, Professor Michele Arslan, Dr. Aram Glorig, Professor Ettore Bocca, Professor Horst L. Wullstein, ex-aquo: Professor Jean Mari Aran and Professor Heim Sohmer, Professor Wolf D. Keidel.

Bell Catalog

The Spring/Summer Alexander Graham Bell Association for the Deaf publication catalog is now available. The catalog features three new books plus many other highly respected educational texts and support material for parents. The texts, reprints, and audiovisual materials emphasize the auditory-oral components of communication. Please contact: Elizabeth Quigley, A.G. Bell Association for the Deaf, 3417 Volta Place, N.W., Washington, D.C., 20007, for your copy (copies) of the catalog.

American Auditory Society Executive Committee Meeting Minutes

DATE: August 26, 1984

PLACE: "Classroom", Santa Cruz Resident Hall, Santa Barbara, CA

TIME: 1:00 p.m.

MEMBERS PRESENT: Charlie D. Anderson, LaVonne Bergstrom, Susanne Kos Blum, Suzanne G. Brown, Earl Harford, Deborah Hayes, David Lipscomb, Ross J. Roeser, Wayne J. Staab, W. Dixon Ward, Don W. Worthington

MEMBERS ABSENT: F. Owen Black, E. Robert Libby, William L. Meyerhoff, James A. Nunley, James J. Pappas, Michael F. Seidemann

GUESTS: Marion P. Downs, Hiroshi Shimizu, Ken Startt

1. President Anderson opened the meeting at 1:08 p.m.

2. The minutes from the 1983 meeting of the Executive Committee were approved.

3. The treasurer's report for the period 1/84 through 7/84 was reviewed and approved.

4. David Lipscomb reviewed the plans for the 1985 meeting in Atlanta. Tad Zelski, the local arrangements chairman, and Ross Roeser met in Atlanta on August 4th and discussed all of the details regarding local arrangements. Dr. Lipscomb identified several individuals who he will appoint to the program committee. The theme for the meeting will be "Technical Innovations in Clinical Hearing Science." The possibility of having a 1/2 day workshop, rather than individual invited speakers, to present information on one topic was discussed. It was decided that the program chairman would investigate this possibility.

A possible Carhart speaker was identified and it was decided that LaVonne Bergstrom would contact this individual to invite him to the meeting. If he accepts, Don Worthington, as the president of AAS, will contact him formally on the behalf of the Society.

5. The procedure for identifying the Carhart speaker was discussed. Since there is no formal procedure established to nominate speakers, it was decided to form a committee consisting of LaVonne Bergstrom (chair), Hiroshi Shimizu, E. Robert Libby, David Lipscomb, and Don Worthington to develop a list of names for Carhart speakers for future meetings. This list will be presented at the 1985 Executive Committee meeting.

6. The 1986 meeting was discussed. It has been decided that the American Auditory Society will meet with the American Speech-Language-Hearing Association in Detroit in 1986. The names of two individuals were presented for program chairman. It was decided that Don Worthington would contact one of these two individuals and request that he accept the position as program chairman. Possible local arrangements chairman were discussed. The idea of holding the meeting in a local facility such as the Henry Ford Hospital, was discussed.

7. It was decided that the 1987 meeting will be held in Las Vegas, NE in conjunction with the American Academy of Otolaryngology/Head and Neck Surgery. The dates for the meeting are September 11-17.

8. Ross J. Roeser was appointed secretary/treasurer for 1986.

9. Suzanne Kos Blum was appointed assistant secretary/treasurer for 1986.

10. LaVonne Bergstrom was appointed as vice president/president elect for 1984-86.

11. A discussion was held regarding the Ear and Hearing editors awards. At the 1983 meeting it was decided that the editors award would be discontinued for a period of one year. Since then several members of AAS took it upon themselves to circulate a petition among the members of the society requesting that the awards be reinstated. This petition was presented to the Executive Committee by President Anderson. After discussion a vote was taken regarding the awards. Seven favor reinstating the awards, one opposed, and two abstained. Based on this vote the editors award was reinstated. It was decided that Bob Keith, as the new Editor In Chief of Ear and Hearing, will be the chairman of the committee to identify papers for Volume V and Volume VI (1984-85). The members of the committee will be the section editors. Ross Roeser will be an ex-officio member of the committee.

12. The CRS Amplifon Award was discussed. This year the CRS committee provided the American Auditory Society with a list of distinguished individuals who were felt to deserve the award in the area of neurophysiology of the auditory system and coding strategies for sound and signal processing. After reviewing the impressive list of candidates it was decided that no additional names would be provided.

A letter will be sent to the CRS committee informing them of this information.

13. The issue of liability insurance was discussed. The question of whether the American Auditory Society should have liability insurance has been raised at several meetings in the past. Investigation of this issue with an insurance carrier revealed that for approximately \$500.00 per year the Society could purchase the insurance. However, after discussion it was felt that this was not a necessary expense and the recommendation was made that the Society not have liability insurance. Ken Startt pointed out that the Williams and Wilkins Company has liability insurance for Ear and Hearing that would protect the editors and authors.

14. In the past, manufacturers have contacted the American Auditory Society to present awards during the annual meeting. This is felt to be a highly worthwhile activity and such activity is encouraged at future annual meetings of the Society. However, it was recognized that some means should be available to monitor and/or control the material that is presented during the awards ceremonies. Thus, the following motion was made and passed: "Any awards presented during the American Auditory Society meetings from outside organizations be given by the president of the American Auditory Society."

15. The issue of CME/ASHA/AMA credits was discussed. It was recognized that in view of certification/licensure requirements, having continuing education unit (CEU) credits for the annual meeting is desirable and should be explored. Several possible plans were outlined, and Deborah Hayes was asked to look into having CEU credits for the 1985 meeting. She will report on this area at the 1985 Executive Committee meeting.

16. Don Worthington reported on the membership/promotion committee. There were 1,516 members of the Society. This compares favorably to last year's membership of approximately 1,325. The membership still is lacking in otologists, with less than a 10 percent representation. This year's promotional activity involved the building of a display that will be set up at the International Audiology Congress in Santa Barbara and at the annual meeting of the American Academy of Otolaryngology/Head and Neck Surgery.

17. Suzanne Kos Blum reported on the qualifications committee. The Executive Committee reviewed the names of 265 individuals who had submitted their applications for membership. All of these individuals have the necessary requirements for membership, including signatures from active members. After reviewing the list the individuals were approved for membership without exception. This list will be published in the upcoming issue of Corti's Organ.

18. Ralph Naunton, chairman of the long range planning committee, was not able to attend the 1984 Executive Committee meeting. In his place Charlie Anderson reviewed data from his report. A questionnaire has been sent to past Executive Committee members, as well as to the present members. Each respondent was requested to provide information on a number of activities that the Society has or should become involved in. As the various activities were presented they were discussed. President Anderson will report back to Ralph Naunton regarding the reaction of the Executive Committee to the issues discussed. It was highly recommended that Ralph Naunton continue as chairman of the long range planning committee.

19. Seven members of the Executive Committee will be replaced by December, 1985. These members include LaVonne Bergstrom (otology), Earl Harford (audiology), Suzanne Kos Blum (audiology), William L. Meyerhoff (otology), James Nunley (hearing aid industry), W. Dixon Ward (hearing science), and Don W. Worthington (audiology). LaVonne Bergstrom, as the chairman of the nomination committee, was asked to identify two individuals and one alternate for each of the seven positions that will be vacated. The individuals nominated should represent the professional areas of the individuals up for election. This list should be presented to President Worthington by the end of October, 1984 so that the candidates can be contacted and the necessary information obtained for balloting in 1985.

20. The report of Ear and Hearing was given by Ross Roeser, Robert Keith, and Ken Startt.

A. Ross Roeser indicated that the transition of the editorship to Robert Keith has been a smooth one. Many discussions have taken place and a formal meeting was on May 8, 1985.

By June, Volume V was filled and all new manuscripts were being forwarded to Dr. Keith. There were enough

manuscripts in the review process left over from Volume V to fill at least one issue of Volume VI.

B. Robert Keith reported on his plans for the journal. The new section editors will be: Dan Schwartz for the Hearing Aids and Aural Rehabilitation Section, Jerry Northern for the Clinical Notes in Audiology section, Gary Neeley for the Clinical Notes in Otology section, Deborah Hayes for the Speech Audiometry section, Lazlo Stein for the electrophysiologic Techniques in Audiology and Otology section, and Eugene Sheeley for Book Reviews. Irving Gerling will continue as the Editorial Assistant. The January/February issue will be devoted to the Nova Scotia Conference in Pediatric Audiology. It was reported that 36 manuscripts had already been received for the period June, July, and August. It was indicated that Ear and Hearing will continue to publish clinically relevant manuscripts and, with only minor changes, the editorial procedures will be essentially the same as the past.

C. Ken Startt reported on the financial condition of Ear and Hearing. There has been a healthy increase in paid subscriptions in the past year. Total paid circulation is expected to reach approximately 3,000 by the end of 1984. Paid advertising will be about the same for 1984, as it was for 1983. Earnings are expected to be about \$10,000.00 for 1984, which will reduce the accumulated deficit to about \$36,000.00. The overall financial picture for Ear and Hearing was reported to be quite good.

21. Suzanne Brown reported on Corti's Organ. The next issue will appear in October, 1984. Paid advertising has not been as available as expected. Plans for Corti's Organ will continue as they have been for 1985.

22. Earl Harford reported that he will make a video tape of Gunar Liden's presentation when he returns to Minneapolis. This video tape will be available for distribution to AAS members at the nominal fee. Announcement of the availability of the video tape will be made through Corti's Organ.

23. The possibility of having a hospitality at the ASHA meeting in San Francisco for the AAS Executive Committee was discussed. Wayne Staab indicated that his company will have a suite and volunteered its use. A time will be set for this hospitality and announced to Executive Committee members.

24. There being no further business the meeting was adjourned.

See you
in Atlanta
Fall 1985

Tracoustics, Inc.

Changes Corporate Structure

Tracoustics, Incorporated has recently announced major changes in its corporate structure. Ernest Butler, M.D. has assumed the position of Chief Executive Officer for the Austin, Texas based manufacturer. Dr. Butler is an Otolaryngologist in Austin and has been a major stock-holder in Tracoustics since its inception 13 years ago.

John Franks, Ph.D. has been promoted to Vice President for Tracoustics' Instrument Division. Dr. Franks joined the company in 1982 after a distinguished academic career in Audiology.

Jeff Schmitt has been named Vice President of the Enclosures Division in the reorganization. Mr. Schmitt is an acoustical engineer, who will also head up Tracoustics new test laboratory.

Wynyard Ellis is now the Corporate Secretary and is Executive Director of Sales. Ms. Ellis has been with Tracoustics for more than nine years and is familiar with all aspects of the company's operation.

Together these four capable professionals make up the Executive Committee for Tracoustics. Under their guidance and leadership, Tracoustics is planning increased sales and continued excellence in the Audiometric Room and Instrument market.

Queens Independent Living Center Expands Services to Deaf

Beginning on August 15, 1984, the Queens Independent Living Center will expand its services to the deaf by having an onsite interpreter available from 5:30-7:30 p.m. No appointment is necessary and people will be seen on a first come first serve basis.

The Queens Independent Living Center, a non-residential resource Center administered by and for disabled people, offers peer counseling, housing assistance, benefits advisement, information and referral and advocacy. Regular office hours are 8:30-4:30 p.m., Wednesdays until 7:30 p.m.

The Queens Independent Living Center is located at 4-21 27th Avenue in Astoria and can be reached by subway to Queens Plaza then Q19 or Q102 bus, or RR to 30th Avenue, then Q18 or Q102 bus. Telephone number for voice 728-0011, TTY 728-7812.

Inter Noise Seminar Offers Two Courses

The Institute of Noise Control Engineering (INCE) is offering two short courses on noise measurement and noise control as part of the 1984 INCE Seminar. The Seminar will precede INTER-NOISE 84, the 1984 International Conference on Noise Control Engineering which will be held in Honolulu, Hawaii on 03-05 December, 1984. One of the two courses will cover: "Techniques of Noise Control." The other will be devoted to "Sound Intensity Measurements." The second short course is being offered for the first time because of current interest in the applications of sound intensity measurements to problems related to noise control.

The short courses of the INTER-NOISE Seminar will be offered in parallel beginning on Thursday, November 29 and concluding on Saturday, December 01. The short courses will be presented at the Westin Ilikai Hotel in Honolulu, Hawaii, the location for INTER-NOISE 84 which will be held in the week following the INCE Seminar.

The staff of the Seminar serves at the invitation of the INCE/USA Board of Directors. All staff members have extensive backgrounds in the field of noise control engineering and sound intensity measurement. The staff members have donated their time as Seminar leaders to further the understanding of the fundamentals of noise and its control and the basics of sound intensity measurements.

Professor Malcolm J. Crocker, Editor-in-Chief of Noise Control Engineering Journal, is the Chairman of the short course on "Techniques of Noise Control." Professor Jiri Tichy of Penn State is Chairman of the short course on "Sound Intensity Measurements."

The "Techniques" short course will appeal particularly to those individuals who are new to the field of noise and its control. The "Sound Intensity" short course will be of interest not only to those who are involved directly in such measurements but to others who wish to become current on the latest technique for noise analysis.

Interest in the INCE short course on "Techniques of Noise Control" has been growing over the years. This will be the twelfth offering. One of the principal objectives of this short course is to enable the participants to acquire an understanding of the fundamentals of noise control so that the state-of-the-art papers presented at INTER-NOISE 84 are accessible to them.

This first offering of the short course on "Sound Intensity Measurements" is in response to the expanding interest in this subject. Recent advances in instrumentation, particularly signal processing software and hardware, have made it possible to measure acoustic intensity directly in the field. This type of measurement has numerous applications, including the determination of the sound power levels and the identification of propagation paths from noise sources.

The INCE Seminar is undertaken by the Institute to fulfill one of its basic responsibilities to the public.

Further information on both of these courses is available from the INTER-NOISE 84 Conference Secretariat, Institute of Noise Control Engineering, P.O. Box 3206, Arlington Branch, Poughkeepsie, NY 12603, U.S.A. Telephone: (914) 462-6719.

Spring 1985

Nominations Open for 1985 BDTAA

The 1985 search for excellence in audiology instruction has begun with the opening of nominations for the 1985 Beltone Distinguished Teaching Award in Audiology (BDTAA).

The BDTAA is the only teaching award bestowed in the field of audiology. To be eligible, instructors must be nominated by a current or former student and have five or more years of experience in teaching audiology.

More than 7000 brochures containing nomination forms were mailed by Beltone to audiology students and department chairmen at universities across the country. Deadline for nominations is April 15, 1985.

The nomination form is one of eight factors weighed by the judges to determine a winner. It is worth 10 percent of the overall evaluation. A new aspect of the judging process is the additional input that is being requested of the nominees's students and colleagues.

The other six factors and their values

1985 Poster Child Chosen for Better Hearing & Speech Month

ROCKVILLE, MD. — Five-year-old Nancy Jones of Warrensville Heights, OH, who is hearing-impaired, has been named the 1985 Poster Child of the Council for Better Hearing and Speech Month, a consortium of 23 national organizations united to

Please see Poster, Page 2

are curriculum vitae (30 percent), nominee's required essay (20 percent), former student evaluation (20 percent), overall impression (5 percent), nominee intention form (5 percent) and department chairman/dean evaluation (5 percent). The title of this year's required essay is "The Future Role of the Audiologist in the Health Care Field."

The 1985 judging panel is composed of 10 outstanding professionals from the field of audiology — including the 1983 and 1984 BDTAA winners — plus one student representative selected by the National Student Speech, Language and Hearing Association. The judges are Charles I. Berlin, Ph.D. (1984 winner), Louisiana State University; Fred Bess, Ph.D., Vanderbilt University; Michael R. Chial, Ph.D., Michigan State University; Marion R. Downs, M.A., University of Colorado; Gloria Garne (student), University of Georgia; Jack Katz, Ph.D., State University of New York; Bob Keith, Ph.D., University of Cincinnati; Geary McCandless, Ph.D., University of Utah; Frank E. Musiek, Ph.D., Dartmouth-Hitchcock Medical Center; Ralph R. Rupp, Ph.D., University of Michigan; and Terry L. Wiley, Ph.D. (1983 winner), University of Wisconsin.

Announcement of the 1985 BDTAA recipient will be made at the Oct. 21 meeting of the American Auditory Society in Atlanta, GA. Beltone will award the winner \$1000 cash and a commemorative plaque. The firm will also host a banquet in the winner's honor at his or her university and will sponsor three lectures by the instructor at leading universities around the nation. An invitation to sit on the 1986 judging panel is also extended.

In addition, the award package includes a \$2500 scholarship from Beltone to the audiology department at the recipient's university, and a \$100 cash award to the student nominating the recipient.

The 1985 winner will be the fourth audiology instructor honored through the program. Beltone established the BDTAA program to recognize contributions by the teaching profession in the field of audiology.

Interested students who were not mailed nominating forms may request materials by contacting Raina Gernstetter, BDTAA Coordinator at Beltone, 4201 W. Victoria St., Chicago, IL 60646.

Samuel Lybarger to Address 1985 AAS Convention

Samuel Lybarger

It has been announced that Samuel F. Lybarger will be this year's Carhart Lecturer at the 1985 AAS Convention in Atlanta. (Further information will appear in the pre-convention issue of Corti's Organ.)

Call for Papers

The 12th annual meeting of the American Auditory Society will be held in Atlanta, Georgia on Monday, October 21, 1985. This year the meeting is scheduled with the annual convention of the American Academy of Otolaryngology — Head and Neck Surgery.

The theme of this year's meeting will be "Technological Innovations in Clinical Hearing Science." The program will incorporate segments containing invited papers as well as contributed papers.

The program committee encourages the submission of papers consistent with the theme of Technological Innovations in Clinical Hearing Science. Papers in other areas, however, may be submitted.

Interested persons are invited to submit six copies of an abstract approximately 300 words in length. The deadline for submission is May 1, 1985. Notification regarding program committee decisions will be mailed to presenters by July 15, 1985.

Abstracts should be sent to:

Michael F. Seidemann, Ph.D.
 LSU Medical Center
 Department of Communication Disorders
 1900 Gravier Street
 New Orleans, LA 70112

promote public information about speech, language, and hearing disorders and to highlight the availability of help for those disorders. Better Hearing and Speech Month will be launched in Washington, DC in May.

Nancy and this year's Better Hearing and Speech Month Chairman, actress Florence Henderson, will serve as national spokespersons for the Council and the more than 22 million Americans with communication handicaps whom it represents.

During May, Nancy will be featured in television, radio, and magazine public-service announcements, and will travel with her parents to Washington, DC to participate in the Better Hearing and Speech Month national kick-off activities.

Nancy's hearing loss developed as a result of spinal meningitis, which she had at eight months of age. She now attends the Millridge Center for Hearing Impaired Children in Highland Heights, OH and enjoys such activities as swimming and bicycle riding with her family.

Major Hearing Aid Study Completed

WASHINGTON, D.C., JANUARY 10, 1985 — A major study of the U.S. hearing-impaired population has been completed by the Hearing Industries Association (HIA), headquartered in Washington, D.C.

In announcing the completion of the twelve-month market research effort, HIA President James C. Keyes noted, "This research is the most complete and comprehensive data now available regarding the approximately 16.4 million Americans who experience some degree of hearing loss." Keyes, who is President of Audiotone, Phoenix, Arizona, continued, "We have analyzed the beliefs and attitudes of a sampling of this population regarding their hearing losses, professional hearing health care, and hearing aid use. We are confident that these findings will enable us to expand and enhance information, services, and products available to America's hearing impaired population."

The study of a randomized sample of 1,550 hearing-impaired individuals was conducted for HIA by the market research firm of National Family Opinion, Inc. of Chicago, Illinois. Marketing Consultant to the effort was Robert E. Burnkrant, Ph.D., Associate Professor of Marketing at Ohio State University. The project was coordinated by HIA's Market Development Committee, chaired by John Zei of Beltone Electronics Corporation, Chicago, Illinois.

The survey sample included 500 hearing aid owners and 1,050 hearing-impaired adults who do not currently own a hearing aid. Based on a response rate of nearly 80% to a 120-item questionnaire, the results obtained are highly projectable to the entire hearing-impaired population in the U.S.

Of major importance is the finding that 6.3 million non-owners of hearing aids — fully 68% of the estimated 10.5 million people who do not currently use a hearing aid — have obtained professional evaluation of their hearing loss. Over 40% have discussed their hearing problem with their family doctor and an equal percentage with an ear specialist; 32% of this group have visited an audiologist, and 10% a hearing aid specialist.

Based on the high percentage of individuals who have sought professional help for their hearing problems, the

survey probed the reasons for an individual's decision to purchase a hearing aid. Survey results confirmed in other industry statistics that approximately 3.9 million Americans currently use at least one hearing aid and an additional 8 million people could benefit from hearing aid use.

Of major importance in a hearing aid purchase is the recommendation to use a hearing aid from a hearing health care provider. Additional elements that encourage a hearing aid purchase are the recommendation of family and friends, and the social advantages of better hearing — easier conversations, better comprehension and improved ability to hear television and radio. According to these survey results, appearance factors and expense do not significantly influence an individual's decision to purchase a hearing aid.

The HIA Market Research Survey also yielded information regarding purchaser demographics, hearing aid sales, product performance and hearing aid batteries. This additional information will assist the industry in carrying out its continued commitment to quality products and service for America's hearing-impaired population.

HIA is the trade association of manufacturers and distributors of hearing aids and component parts, and suppliers to the industry.

Amplifon Winner Announced

The Amplifon Research and Studies Center Board of Directors met on November 30th in order to scrutinize the votes which had arrived from the national and international societies for the election of the winner of the 1984 Amplifon CRS International Prize.

The winner, resulted from the pool, is prof. P. Dallos from Auditory Physiology Laboratory and Department of Neurobiology and Physiology of the Northwestern University, Evanston, Illinois.

I wish to thank you very much for your precious cooperation. The prize awarding ceremony will be held on March 22nd, 1985.

KNUD TERKILDSEN, M.D. 1918 - 1984 A Memoir

Knud Terkildsen

It is with great sadness that we record the passing of Knud Terkildsen in September of this year. He leaves a widow and two daughters and we feel sure that all our readers will join us in sending sympathy to them. He touched all of our lives and the lives of countless others through his work in the hearing health field, whether as researcher, lecturer, physician, colleague or friend.

To a privileged few who counted him as friend he was unstinting in giving of himself and his time; to those who counted him as colleagues he was that rarity among men — one who was untouched by professional jealousy; to his patients he was the caring physician whose only frustration was that medical science was unable to do more to alleviate human suffering; in the lecture hall he was known for the precision of his arguments, infinite care in preparation, and generosity in sharing his knowledge; as a researcher he is best known for teamwork — usually as team leader but equally at home as team member.

Knud Terkildsen — "Terk" to many in the hearing field — trained at the University of Copenhagen, did his Residency in Kansas and became the Chief of Audiology in Copenhagen University Hospital, a position he held until he took early retirement in 1983. By one of the great ironies of life he succumbed to one of the disorders to which he devoted a great deal of research.

Best known for his work in the field of impedance audiometry — he was a member of the triumvirate of Terkildsen, Scott Nielsen and Madsen whose collaboration produced the electro-acoustic impedance bridge — in later years his contribution was in the field of Evoked Potentials. His work was generally published in European journals — predominantly Scandinavian Audiology — but many a contribution has appeared in the more familiar U.S. publications.

Since the very early 1970's, Terk was a regular visitor to these shores and was to be seen at ASHA, at AAO and at the San Diego meetings which became famous as "the Annual Evoked Response Symposium". He also traveled extensively in Latin America and the Far East as lecturer and researcher and received a constant stream of visitors from around the world in his office in Copenhagen, one of whose walls adorned with a "Metz Bridge" — invented by Otto Metz, a fellow Dane who is sometimes called the grandfather, while Terk is known as the father of impedance.

In his private life Terk lived modestly with his family, and took great pleasure in taking his dog for walks in the country around his home, and in the peaceful enjoyment of the simple pleasures of life.

A many-faceted man, we shall not see his like again. He will be sorely missed.

Meet the Candidates for the AAS Executive Committee Election

This summer an election will be held to replace returning members of the Executive Committee of the American Auditory Society. We have asked each nominee for the office to provide the membership of the Society with some basic bibliographic information, and to provide their thoughts regarding the future direction of the Society. (A membership ballot will be mailed to you shortly.)

Patrick E. Brookhouser, M.D., F.A.C.S. Director, Boys Town National Institute for Communication Disorders in Children, Flanagan Professor and Chairman Department of Otolaryngology and Human Communication, Creighton University School of Medicine, 555 North 30th Street, Omaha, Nebraska 68131. Bachelor of Science, summa cum laude Creighton University - 1962. Doctor of Medicine Johns Hopkins University School of Medicine - 1966. Internship, Residency and Fellowship in Otolaryngology Johns Hopkins Hospital, Johns Hopkins University School of Medicine.

It is somewhat ironic that we profes-

sionals representing disciplines concerned with normal and disordered human communication have, in the past, experienced communication difficulties among ourselves and our professional organizations. Too often, the occasional breakdown in communication among our senior professional society representatives has been interpreted, incorrectly, by policy makers and funding agencies as representative of a true schism among physicians, clinicians, and scientists in the communicative disorders field. The American Auditory Society provides a unique forum to foster collegial interaction among all disciplines interested in the diagnosis, treatment and prevention of hearing disorders. It is important to provide young professionals in our respective fields, particularly otolaryngology residents, with proper role models in the form of senior otolaryngologists who interface in a productive fashion with other clinicians and researchers in the auditory sciences. It has been my privilege, as Director of the Boys Town National Institute for Communication Disorders in Children, to help foster these relationships among our clinical and research staff to the mutual benefit of all concerned. The promotion of mutual trust and respect for the unique viewpoint and skills which each discipline brings to our joint clinical and scientific endeavors should continue to be a major goal of the American Auditory Society.

Robert A. Dobie, M.D. M.D. Stanford University, 1971. Associate Professor, Dept. of Otolaryngology, University of Washington, RL-30, University of Washington, Seattle, WA 98195.

The American Auditory Society fills a unique niche among professional organizations in the field of hearing. Recognizing that, for legitimate reasons, separate societies have been formed to serve the

needs of otolaryngology, audiology, the hearing aid industry, and basic scientists working in audition, the AAS offers an ecumenical forum for all who are interested in hearing and its disorders. By careful design, our Society has transcended parochialism and established a firm reputation; both its meetings and its journal satisfy a persistent and growing need for interdisciplinary communication.

I see no need for major shifts in goals or strategies for the Society. Annual meetings should continue in conjunction with ASHA and AAO-HNS; free-standing meetings would be a mistake. *Ear and Hearing* should continue to grow in stature as a strictly referral journal, with a small proportion of invited review or tutorial papers. The Society should regularly review the professional composition of its membership and its journal contributors, and take appropriate steps, when needed, to encourage balanced representation.

Allison M. Grimes. Humboldt State University, California: BA 1973, MA in Speech Pathology, 1974. University of Denver, Colorado: MA in Audiology, 1975; Assistant Chief of Audiology, The Clinical Center, ACRF 5C306, The National Institutes of Health, Bethesda, MD 20205, and Clinical Supervisor in Audiology, University of Maryland, College Park, MD 20742.

The American Auditory Society is the national organization which represents most completely the interaction of all professional groups involved in the study of audition. The Society provides a unique opportunity for non-political dialogue and dissemination of information among a number of specialties. It is clear that a successful relationship among those serving the needs of the hearing impaired is of the greatest importance to professional and patient alike. While it is to the mutual advantage of all such disciplines to be proportionately represented in the AAS, at this time audiologists account for the overwhelming majority of the membership. This is a less than satisfactory situation, and one which I believe deserves continuing effort to remedy. In order for the aims

of the Society to be fully realized, the resources and concerns of audiology, otology, education and industry must be represented. Cooperation and collaboration by all of us will ensure the aims of the Society: knowledge and understanding of the auditory process, conservation of hearing and rehabilitation of the hearing impaired.

Barbara Kruger, Ph.D. C.U.N.Y. Graduate School and University Center, the City University of New York, Dept. Speech and Hearing Sciences, Doctorate in Audiology and Hearing Sciences, 1974. M.A. Audiology and Speech-Language Pathology, Queens College of C.U.N.Y. Dept. Communication Sciences, 1971. CCC/A.S. B.A. Psychology major, Biology and Speech Minors, Queens College C.U.N.Y., 1967. Director of Audiology and Speech-Language Pathology and Director of Audiology Research Laboratory, Dept. of Otorhinolaryngology, Albert Einstein College of Medicine and Montefiore Medical Center, VE5C8, 1300 Morris Park Ave., Bronx, New York 10461.

The American Auditory Society provides a unique forum for communication among the largest group of professionals with different backgrounds who serve the hearing impaired. True to its purpose, which is to foster and disseminate knowledge about the auditory process and hearing impairment, the AAS draws its membership from the various disciplines with special expertise in hearing. It is the only organization of its kind devoted solely to hearing. The society offers informal and formal exchange of ideas concerning clinical practice and scientific research through its annual meeting and its quality publication *Ear and Hearing*. The greatest strength for the future of the AAS, however, is as an arena for dialogue among its diverse membership. The vitality of the society will endure by encouraging understanding of and respect for the strengths, individual differences, and perspectives of each of the specialties which share a common interest in audition and hearing health care.

David J. Lilly, Ph.D., University of Pittsburgh, 1961, Director of Audiology, Good Samaritan Hospital and Medical Center, 1015 NW 22nd Avenue, Portland, OR 97210.

In just over a decade, the American Auditory Society has emerged as a major association for many workers in audition. The success of the society stems, in part, from the diverse backgrounds of its members. Indeed, the American Auditory Society has been unique in its ability to provide a common forum for audiologists, engineers, hearing-aid specialists, otolaryngologists, neurophysiologists, physicists and for psychoacoustics.

During this same period our journal has become an important archival repository for manuscripts concerned with near-

Please see Candidates, Page

POSITION AVAILABLE DIRECTOR AUDITORY EVOKED POTENTIAL LABORATORY Department of Otorhinolaryngology Division of Audiology and Speech-Language Pathology Albert Einstein College of Medicine of Yeshiva University and Montefiore Medical Center Bronx, New York 10461

Primary responsibilities include coordination and provision of AEP clinical services, and active research. This position provides an excellent opportunity for challenging clinical research with a multi-disciplinary team. A suitable candidate should be prepared to conduct research applying evoked response technology to areas of auditory physiology and psychoacoustics. Demonstrated research interest and expertise in understanding the normal and abnormal development of the auditory system is desired. The candidate would participate as a co-investigator in the Clinical Research Center in Communicative Disorders in Children along with colleagues in Audiology, Otolaryngology and in Neuroscience.

Clinical experience with sophisticated auditory evoked potential recording (BSAEP & MLP) is required. Additional responsibilities include teaching medical students, and residents. Administrative experience is desired, but not required. Doctorate is required. ASHA Certification (CCC-A) and eligibility for New York State Licensure are preferred. The position offers a full-time faculty appointment. Rank and salary are commensurate with qualifications and experience. AECOM/MMC is an EOE.

Candidates

Continued from Page 3

every aspect of audition. The rapid and equitable review process instituted by *Ear and Hearing* and its minimal publication lag are attracting first-rate manuscripts. Moreover, the "special issues" on selected topics have become required reading in many training programs.

The growth and success of the American Auditory Society and *Ear and Hearing* could not have occurred without the dedication and efforts of its officers, editors and executive committee. In consequence, I consider it an honor and a challenge to have been chosen by the Nominating Committee to serve as a candidate for election to the Executive Committee. If elected, I shall do my utmost to foster the continued growth of our society in an environment that emphasizes scientific achievement and clinical excellence while avoiding the "professional" and political issues that have attenuated the growth of so many other organizations.

Serge A. Martinez, M.D. Doctor of Medicine, University of Miami School of Medicine, 1969. Professor of Surgery, Director, Division of Otolaryngology - Head and Neck Surgery, University of Louisville. Myers Hall, University of Louisville Medical Center, Louisville, Kentucky 40292.

The American Auditory Society has emerged into a position of respect with regard to its role as coordinator of activities and education relative to audition. Its publication is of high quality and its members support its annual meetings. However, it seems that the organizational membership is predominately non-physician in nature and therefore a give and take of theory and practice is limited to relatively few of all the individuals who provide patient or client care. Indeed, most of the articles produced in *Ear and Hearing* are of interest to the audiologist or basic researcher with very few being geared to the general otolaryngologic public. This is unfortunate since most diseases seen by practitioners are related in some way to the ears and hearing.

In order for the Society to be successful in its aims as described in the bylaws, and

increase the interdisciplinary interaction, it should add emphasis to the clinicopathologic aspect of ear disease and/auditory dysfunction, encourage clinical papers in the journal and market itself more enthusiastically at national and local meetings of physicians and non-physicians alike.

Richard T. Myamoto, M.D. F.A.C.S. Wheaton College, Wheaton, IL, B.S., 1966; University of Michigan, Ann Arbor, MI, M.D., 1970; University of Southern California, Los Angeles, CA, M.S. (Otolaryngology), 1978; Indiana University School of Medicine, Indianapolis, IN, Resident in Otolaryngology, 1975; Otolaryngologic Medical Group and St. Vincent Hospital, Los Angeles, CA., Fellowship in Otolaryngology and Neurology, 1978; Associate Professor & Chief of Otolaryngology, Dept. of Otolaryngology - Head and Neck Surgery, Indiana University School of Medicine; Board of Governors, American Academy of Otolaryngology - Head and Neck Surgery; Secretary-Treasurer, Indiana Academy of Otolaryngology - Head and Neck Surgery.

It is a privilege to share this candidacy and voice my support of the stated aims of the American Auditory Society. The Society provides a unique forum for interaction among professionals with diverse backgrounds and expertise who are involved with the study of hearing and the rehabilitation of the hearing impaired. The future growth and strength of the Society is dependant upon its continued ability to promote this open dialogue and cooperation. As an otologist, I understand the importance of communicating with professionals of related disciplines who have a common interest in hearing because of the increasing complexity of knowledge. Considering the depth and wealth of experience represented in the Society's broadly based membership, I perceive the American Auditory Society as a key organization in our quest to stimulate research and provide care to our hearing impaired patients.

David A. Preves, 1963 B.S., M.S. in Electrical Engineering University of Illinois; Ph.D program in Biomedical Engineering University of Minnesota

1980-present; Chairman, ANSI committee for hearing aid standards; Vice President, Engineering, Starkey Laboratories, 6700 Washington Ave. S. Eden, Prairie, MN 55344; 800-328-8602.

It is truly an honor to have been chosen as a candidate for the Executive Committee of the American Auditory Society. My interest in actively participating stems from the desire to better the communications between hearing aid manufacturers, audiologists, psychoacousticians and physicians working in the hearing health care field. Only through such a diverse group with so wide a variety of perspectives working together can we hope to meet the challenge of providing the best possible hearing rehabilitation.

Formulating a viable model which represents all of the attributes of the auditory system has been a long-standing problem. Once we have obtained a better understanding of how the auditory system functions though the efforts of auditory physiologists and psychoacousticians, it may be possible to design more effective hearing aids. Although, the design and effectiveness of the hearing aid prosthetic itself is vital, the importance of the one-on-one rehabilitation process performed by the audiologist during the fitting and post evaluation stages cannot be minimized. An organization such as the American Auditory Society is the ideal body within which to exchange ideas and further knowledge about such considerations.

William F. Rintlemann, Ph.D. B.S., Arizona State University, 1952; M.A., Indiana University, 1957; Ph.D., Indiana University, 1960; Post-doctoral Fellow, Northwestern University, 1961-63; Present position: Professor and Chairman Department of Audiology, Wayne State University School of Medicine, 4201 St. Antoine, 5E, Detroit, MI 48201.

A unique feature and major strength of the American Auditory Society is that the membership is composed of a broad spectrum of individuals with varying interests and activities related to hearing impairment, hearing conservation, and aural rehabilitation. The range of activities of the membership encompasses: 1. Teaching; 2. Research; 3. Clinical evaluation/patient management 4. Aural rehabilitation including hearing aid selection, fitting, sales and counseling; and 5. Product (i.e. hearing aids, audiometers, etc.) development, engineering, manufacturing and sales. No other organization has such a broad scope of activities related to serving the hearing impaired. Because the membership of the American Auditory Society deals with nearly every aspect of serving the needs of hearing handicapped persons, the Society has a unique opportunity to serve as a catalyst for not only technological development of amplification devices, but also advancement in patient evaluation/management skills.

The leadership of the American Auditory Society should strive to find the best possible ways to maximize open communication among all of its members in

order to foster "state-of-the-art" advances in education, research, patient care and product development.

Laszlo K. Stein, Ph.D. B.S.E. Northern Illinois University, 1953; M.A. Northwestern University, 1957; Ph.D. Northwestern University, 1963. Director David T. Siegal Institute for Communicative Michael Reese Hospital and Medical Center; Associate Professor Department of Surgery (Otolaryngology) University of Chicago. Lake Shore Drive at 31st Street, Chicago, IL 60616 (312) 791-2910.

Expansion of clinical knowledge in the field of hearing and its disorders will increasingly depend on a healthy interaction among a wide variety of once compartmented fields. Contributions by otologic surgery, psycoustics, electrophysiology, neurobiology, and computer science, to name only a few, illustrate the mix of sciences that have yielded some positive effects as well as considerable promise. Growth of knowledge, however, tends to be asynchronus, especially when findings must be interlocked to form specific clinical strategies.

In my view, the American Auditory Society is in a unique position to foster the mix of sciences and disciplines necessary to achieve unique and worthy advances in clinical practice. The very nature of the Society's clinical practice — open to anyone with scientific or professional experience who has demonstrated an interest in the field of hearing — is key to the interaction of professional disciplines up until quite recently thought to be outside those traditionally utilized by otology and audiology. By actively promoting the interactive nature of research for the auditorially impaired through its sponsorship of meetings and publications, the Society fills a vital clinical scientific, and humanitarian role. The expansions of this role should be the paramount objective of the Society in future years.

Michael C. Vivion, Ph.D. Product Marketing Manager, Nicolet Instrument Corporation, Biomedical Division, 5225-4 Verono Road, Madison, WI 53711. B.A. in Speech Pathology and Audiology, 1968, Baylor University, Waco, Texas; M.S. in

Please see Candidates, Page 5

Candidates

Continued from Page 4

Communicative Disorders, 1971; Ph.D. in Communicative Disorders, 1976, University of Wisconsin-Madison.

As society enters the age of information, computers and accelerated technological advances, I believe that the various hearing-related disciplines will experience considerable pressure to adopt and utilize the latest technological advances. Evidence of this already can be seen in such areas as cochlear implants, digital hearing aids, computerized patient record keeping, to name just a few. As we, the members of the American Auditory Society, implement these innovations in order to perform research and to provide service and healthcare to the hearing- and communicative-impaired, the needs for information exchange, for standardization, and for quality assurance will also become greater. Given the multi-disciplinary nature of the Society, I think it is an ideal group to address these needs and issues. Through its annual meetings and its publication, *Ear and Hearing*, the Society has the opportunity to lead in the development of standards for new diagnostic testing methods, of protocols for information exchange and record keeping, and of criteria for the performance of devices for the hearing-impaired. I believe the Society has grown and matured sufficiently that it can now call upon the resources of its members to generate proposals for solutions to these needs as well as others that I have not mentioned or that are unforeseen at present.

Kenneth E. Wolf, Ph.D. B.A. and M.A., University of California, Santa Barbara, 1970 and 1972; Ph.D., University of Wisconsin, Madison, 1977. Chief of Communicative Sciences and Disorders and

Assistant Professor of Otolaryngology, King/Drew Medical Center, 12021 So. Wilmsington Avenue, Los Angeles, CA. 90059.

The membership of the American Auditory Society enters the second half of the 1980s facing newer and more specific challenges. Many changes in the health care delivery and educational systems will impact us.

The short history of the AAS has emphasized that all aspects of the hearing health community be represented among the membership and Executive Committee. Audiologists, hearing aid specialists, hearing scientists, and otologists have productively interacted at the annual meetings. The Society's publications have fostered increased intellectual growth and promoted diagnostic, habilitative and rehabilitative advances. Future progress will be achieved through continued interdisciplinary efforts. Collective activities across specialty areas are needed to expedite expansion of science and service directed toward prevention, detection and treatment of the hearing handicapped.

Caution Required When Removing Earwax

WASHINGTON, D.C. — If it is smaller than your elbow, it does not belong in your ear, claims a new leaflet published by the American Academy of Otolaryngology — Head and Neck Surgery. The AAO-HNS is the national society of doctors who treat ear, nose and throat and related areas of the head and neck.

Reaching for a cotton swab to remove earwax is not the method otolaryngologists recommend to clean ears. According to the leaflet, the eardrum is one of the most delicate tissues of the body and one of the most easily injured. Using a cotton swab to remove earwax, or absent-mindedly playing with a bobby pin inside your ear are possible ways to push wax further down the ear canal and block hearing, and also injure the skin of the ear canal.

Earwax, which is formed by glands in the skin of the outer part of the ear canal, does have an important function — to trap dust and other particles and prevent them from reaching the eardrum. Usually, the wax accumulates the particles then dries up and falls out by itself. But if wax is accumulated near the ear canal and is blocking your hearing or the hearing of someone in your family, it needs to be removed.

Otherwise, this four step method should be employed to effectively wash out earwax:

1. Begin by softening the wax before you try removing it. Instill in the ear canal several drops of a product such as Deborx twice a day.

2. Use bath temperature water and an infant enema or a plain rubber bulb syringe.

3. Lean over a sink, and with one hand pull the outer ear upwards and backwards while squirting water into the ear with the other hand. When finished, turn and pull the ear downward to let the water drain out. You may have to repeat washing 10, 20 or more times if the ear is still blocked. Watch for the wax to fall out.

You can prevent "swimmer's ear" by placing an eye-dropperful of rubbing alcohol into the ear canal and then letting it drain out. Don't eliminate this step — it is important and could prevent future problems.

To keep your family's ears clean and healthy, request a single complimentary copy of the new "Earwax" leaflet by writing: AAO-HNS, 1101 Vermont Ave., N.W., Suite 302, Washington, D.C. 20005. Please specify "Earwax" leaflet and enclose a stamped, self-addressed business size envelope. Multiple copies are available for sale; contact the Academy for details.

7th Run for Better Hearing...

A Marathon Challenge for Hearing Health Team!

Record entries for the 26-mile challenge in the 1985 "Run for Better Hearing" include 33 hearing help providers from across the country and abroad. They include ear doctors, audiologists, hearing aid specialists, manufacturers, suppliers and researchers—representing the interdisciplinary support forging BHI as the hearing field's most cost-effective public education program.

The seventh annual Run is a fund-raising effort to strengthen BHI hearing awareness projects. Broadcast and print media have donated the equivalent of more than \$102 million in commercial time and space to BHI hearing help messages, highlighted by famous Americans who overcame hearing loss. They include Art Carney, Norm Crosby, Phyllis Diller, Nanette Fabray, Lou Ferrigno, Lorne Greene, Florence Henderson, Bob Hope, Kiel Martin, Clara Peller, Frankie Valli, Keenan Wynn, and others.

1985's Run doubleheader features BHI executive director Joe Rizzo in his sixth Boston Marathon on April 15. Then on June 15, in Duluth, MN, Joe will be joined in Grandma's Marathon by: Bob Hanrahan, Wilmington, DE; Jim Keisow, Menomonie, WI; John, Geri and Mark Keisow, Eden Prairie, MN; Jim Anthony Kolokoski, Elm Grove, WI; Anne L. Kuklinski, Champaign, IL; Becky Kurtz, Superior, WI; Arnie Monk, Manitoba, Canada; Randy Nelms, Jr., M.D., St. Paul, MN; Nita Marie Rizzo, Alexandria, VA; Stephen Richard Rizzo, Jr., Ph.D., Chillicothe, OH; Ross J. Roeser, Ph.D., and Sharon Lynn Roeser, Dallas, TX; Emil Strickler, Singapore; Wayne Lee Whitney, Strum, WI; Don Worthington, Ph.D., Dallas, TX; John N. Beall, K. Jeffrey Dahlberg, Tod Eckberg, Richard Edward Marschinke, Leonard L. McMillion, all from Dahlberg Electronics, Golden Valley, MN; Charles Best, Duncan F. Clifton, Byron L. Nielsen, Gary C. Salter, David Edward Somppi, Dr. Richard H. Tomlinson, all from Linear Technology, Ontario, Canada; Steven C. Hannibal, and James D. Kothe, both from Oticon Corp., Green Brook, NJ; Frank E. Trette, and David Lee Wessell, both from Phonic Ear, Mill Valley, CA.

Run Volunteer Committee

This year's Run steering committee includes Al Bruce, chairman, Starkey Labs; Jim Anderson, Qualitone; Jane Hixson, Dahlberg; Glenn Kennedy, Hearing Services; Bud Raas, Earmold Design; Bob Tischbein, Starkey; and Mary Weber, Activair.

"We're urging everyone to pledge their special support to this year's campaign so BHI will continue to run strong," said Run committee chairman Al Bruce. "Tax-deductible contributions will reach far beyond the 26 miles, 385 yards that our 33 runners will tackle this year."

Hearing Instruments magazine, Duluth, MN, will continue to provide a vital role in promoting and coordinating the Duluth Run activities, and the Hearing Journal, Ayer, MA, will extend its special support at the Boston Marathon.

Last year's "Run for Better Hearing" finishers in the Duluth marathon included (top l-r): Wayne Whitney, hearing aid specialist; Duncan Clifton, hearing industry supplier; George Hicks, M.D., otolaryngologist; Mead Killion, Ph.D., industry researcher; (bottom l-r): Barb Friedman, audiologist; Joe Rizzo, BHI executive director; and Ross Roeser, Ph.D., BHI board member.

Oral Communication Possible for Many Deaf

Oral communication is an option that is open to many deaf people. This communication mode requires the deaf person to use spoken language directly with another speaker of the same language, whether hearing impaired or not.

The means of receiving and understanding spoken language for the oral deaf person is a combination of lipreading (more accurately termed speechreading) and amplified hearing. Most deaf people (90-95%), even those profoundly deaf, have a small amount of hearing that may respond to amplification. In many cases, the amplification reaches the decibel levels of some speech sounds, the vowels in par-

ticular; short of this, amplification can provide information about intonation patterns.

A person born with a severe or profound hearing loss, or who becomes deaf before the age of about two, does not have the benefit of normal language development, which is a complex process requiring massive amounts of exposure to language and a patient (though unconscious) trial-and-error campaign on the part of the young child in terms of expression and reception.

No child is too young for a hearing test or too young for the parents to begin observing his or her responses to sound. For ex-

ample, most children from birth to about three months are startled by loud sounds and soothed by their mothers' voices. During the next three-month period, they turn their eyes and head to try and locate sounds, and they enjoy playing with noise-making toys. From about six months to 10 months, children respond to their own names and can understand common expressions such as bye-bye and no. From 10 to 15 months, they can usually point to or look at familiar objects or people when asked, and they can mimic simple words and sounds. Finally, by the time a child is 1½ years old, he or she will be able to follow simple spoken directions and have a sizeable vocabulary of single words.

Any parents or professional in contact with a baby who seems to have a hearing problem should arrange for the baby to be seen by a physician or speech and hearing clinic as soon as possible. It is never too early, and it never makes more sense to "wait and see."

The Alexander Graham Bell Association for the Deaf, which promotes oral communication, can supply information regarding the nearest available audiologic speech training services for locations throughout the United States and many parts of the world. The Association's address is 3417 Volta Pl., N.W., Washington, D.C. 20007.

Soundville

By: Marshall Chasin, M.S.

Editor's note: The following is an interesting story by Marshall Chasin that he uses as a primer to his earmold acoustics class.

Soundville was a happy place. No starvation, no unemployment, and no fluctuating currency. The citizens were known as sounds. Sociologists tell us that Soundville had two groups of citizens; the low ones and the high ones. The low ones were big, rather dumb, but very friendly. The high ones tended to be small, nervous, very intelligent and almost painfully claustrophobic. Together they lived peacefully and prosperously.

Perhaps the most interesting aspect of Soundville was the architecture of the homes. The low ones lived in big houses, but they didn't have any doors. They could go right through the walls! The high ones had beautiful log houses for everyone to see. The doorway was so large that it generally took up an entire side of the house. I guess that since the high ones were so claustrophobic, they needed such big doors. They hated to be closed in.

The low ones had some distant cousins who they generally didn't like to talk about since the neo-killion wars ended. People knew them only as the mid ones — the evil ones. They tended to run around and make life harsher for everyone else. The evil minded ones needed a small door in their houses — that is how you knew them. Besides that, they were ugly.

The inhabitants of Soundville were famous for their parties. All of the parties

and gatherings were held at the homes of the high ones. After all, the high ones could not visit the low ones in their homes. They would be so claustrophobic that they really wouldn't enjoy the parties. If you ever got lucky enough to be invited to a party in Soundville, you would notice that there was rarely a time when the high ones were alone. Sometimes there were so many low ones around, that you didn't even know if a high one was at home! Occasionally, a mid one — an evil one, wandered in off the street, and ruined the party for everyone. Parties were so much more enjoyable if you blocked them out.

The high ones and the low ones got along famously. In fact, one could say that life in Soundville would be boring without the high ones, and unnatural without the low ones. The high ones were always telling information-packed stories to the low ones. But, sometimes the low ones were too friendly — they overstayed their welcome. Subsequently, the high ones rarely got a good night's sleep. It's understandable that many of them died young. Unfortunately, it was a vicious circle. As soon as some high ones died off, the low ones felt so guilty that they visited them even more. I guess they didn't want them to be alone in their time of grief. Because of this, the high ones only had a lifespan of 40-50 years.

In many ways, it wasn't fair. The low ones could go home and rest anytime they wanted and the high ones couldn't (or wouldn't) visit them. After all, it would be too claustrophobic without doors. Understandably, they had long healthy lives. They generally lived to be about 75-80 years of age.

Life in Soundville went on this way for many, many years, until one day the machines arrived! When they first arrived, people thought they were evil monsters who made life harder. In many ways, they acted like the evil mid ones. There were some who thought they were the evil ones, only in disguise! But as time went on, the people of Soundville came to be more friendly with the machines. They were invited to the parties and slowly they became accepted. The machines had one feature that was unique to Soundville. They could bring the high ones back to life! The new high ones were very weak, but as time went on, they grew stronger and stronger, telling more and more interesting stories.

Today, the people and machines of Soundville live happy and long lives. The evil mid ones rarely bother them anymore, although they are still around.

NHA Moves

The National Hearing Association recently relocated its national headquarters to Downers Grove, Illinois. "After seven years of residing at the same location in Oak Brook, Illinois, we found that we had outgrown the space where NHA first began and has since flourished," stated Christian Rosenbach, Executive Director for the national organization.

The new address and phone number for the National Hearing Association are:

1430 Branding Lane
Suite#122
Downers Grove, IL 60515
(312)810-0401 Voice or TDD

The Association invites anyone living in an area convenient to the new location to stop by for a personal visit.

BUYER'S GUIDE

Integrated Systems for Clinical Care

TRACOUSTICS' Integrated Clinical-Diagnostic Systems provide the utmost in capability and economy. The TRACY Evoked Potential System presents the ultimate in obtaining, analyzing and storing auditory evoked potentials at the lowest price in the industry. EARSCAN opens new vistas to the measurement of middle-ear immittance and reflexometry. The PROGRAM III Clinical Audiometer holds its place as the first and most full-featured micro-processor based audiometer available.

Continue to look to **TRACOUSTICS** for the highest quality in Audiometric Rooms and Suites with a complete line of enclosures for clinical, medical and research use. We have the flexibility to design a Room or Suite to meet most any need or budget. Our planning assistance will save you space, our shipping schedule will save you time, and our designs will save you money.

Increase diagnostic capabilities with the addition of a **TRACOUSTICS ENG System**, complete with a mobile integrated cart, ENG examination table, and a digital light bar with stationary, optokinetic and pendular targets.

Run for A.A.S. '84

The hills and valleys of beautiful San Francisco set the course for the 1984 American Auditory Society five mile fun run in association with the 1984 ASHA convention. The theme, "Run for Your A.A.S." was reflected on the commemorative tee shirts sported by the loyal members participating and observing. See you next year!

SUMMER 1985

BHI to explore motivation of hearing impaired

WASHINGTON, D.C. September 1, 1985 — Better Hearing Institute will launch a series of focus group interviews in major U.S. cities next month to study factors motivating hard-of-hearing people to obtain available hearing help, according to Richard T. Burger, Institute president. Pilot sessions were held last month at Northwestern University in Evanston, IL. The regular sessions are scheduled to begin in October and will be conducted in Chicago, Boston, and Los Angeles.

Results are expected to help the Institute to further refine its public information projects and to design future messages for maximum effectiveness.

BHI commissioned NFO Research Inc., Chicago, to conduct sessions with two separate groups, one involving only hard-of-hearing people, another with adult relatives living in the same household. Rationale is that relatives of the hearing impaired may persuade loved ones to obtain hearing help after exposure to public information messages. In the hearing impaired groups, half of the members will have already sought professional help, with the

other half not yet doing so.

In the Northwestern University pilot, one focus group consisted of people with hearing problems, and their spouses were interviewed in separate session. Both groups reviewed several current BHI television public service messages. They then were encouraged to discuss their reactions and their own personal experiences regarding: (1) factors leading them or their spouses to seek professional help, (2) factors tending to prevent them or their spouses from going for such help, and (3) what messages they believe would motivate people with uncorrected hearing problems to obtain available help.

The pilot was made possible by the generosity of Knowles Electronics and its marketing staff, which is assisting BHI in the focus group series.

"We especially appreciate the tireless efforts of Reg Garratt with this project," said Burger, who previously appointed Garrett to chair a board market research subcommittee. Garratt, BHI secretary, is vice president of marketing for Knowles Electronics.

SHHH is people

Deaf people make themselves heard — few hear about hard of hearing people. To counteract this situation and help such people help themselves, a national organization was formed in late 1979. SHHH (Self Help for Hard of Hearing People, Inc.) serves the needs of those who suffer hearing loss, with emphasis on those who are partially deafened. SHHH teaches them about hearing loss and how they can deal with this problem, as well as continue personal growth and development. SHHH places its emphasis on the person, not the problem.

SHHH actively seeks out those who suffer from hearing loss. It involves them in local chapter meetings and community activities in the belief that education and service are the keys to improvement of the person.

SHHH was founded by Howard E. "Rocky" Stone, who lost his hearing during World War II. Nevertheless, he had a very successful career with the CIA. He is

proud of the fact that he rose to senior officer status, not as an analyst dealing with problems on paper, but in operations where the emphasis was on people and effective communication. Although audiologically deaf, Stone is functionally hard of hearing.

SHHH was founded on the conviction that little progress can be made in helping the hearing impaired until both those who hear well and those who do not, better understand the nature, cause, complications and possible remedies of hearing loss.

SHHH is concerned also with education of hearing people. They are encouraged to join in the fight against America's most pervasive physical handicap. The services of SHHH include: a Journal about hearing loss (six times a year); a periodic SHHH Newsletter; a Chapter Manual; remedial aid discounts; referrals and advisory services; information and resource center; advocacy and representation; a national constituency and conventions.

Etymotic research, alive and well after two years

July, 1985 marks the completion of the second year for Etymotic Research. Mead Killion began the company in 1983 to develop a line of products that were needed for hearing testing and hearing aid modification.

Shortly after the company was founded, Ed DeVilbiss joined Mead as a partner and business manager. As the business expanded, they were joined by Don Wilson and Jon Stewart in engineering, Connie Miezio as secretary, and Thann Killion as assembler.

To date, three products have been introduced. The fastest growing product line is a series of insert earphones. One is an alternative for conventional TDH-39 headphones to be used by otologists as well as audiologists. In addition, this line includes two higher frequency (50 Hz to 16K Hz) in-

sert earphones which have been popular with those doing auditory research.

A second product, the open-canal, reverse slope, K-BASS hearing aid has proved an effective fitting for a rare type of loss. Work in this area has led to a series of earhooks which will be available later this year and which will solve several difficult fitting problems.

The final product is a highly accurate probe microphone custom built for research. This has led to the development of a low noise microphone, also for research, to measure cochlear emissions.

Killion indicates that the increasing sales of these products has been most satisfying, since it should ultimately permit him to devote more time to his primary interest which is new product research and development.

SEI now certifying hearing protectors

A third-party certification program for hearing protection devices has been initiated by the Safety Equipment Institute (SEI) with the authorization of the U.S. Environmental Protection Agency (EPA).

The SEI program parallels an EPA program mandating uniform testing of hearing protectors and assigning them a noise attenuation value called the Noise Reduction Rating (NRR). Under the EPA program, which has been unfunded for years, the NRR was indicated on a label affixed to packaging of hearing protection devices.

"The EPA and SEI have signed a Memorandum of Understanding that authorizes the use of the SEI Mark on the NRR Label and recognizes the SEI Program," said SEI Chairman of the Board, George E. Smith. "This means that for the first time in several years an active program exists for the testing of hearing protection products."

The testing and certification program applies to ear plugs, circumaural devices, cap-mounted devices and supra-aural devices.

Testing will be conducted by Dr. Paul L. Michael and Associates, Inc., in conjunction with ANSI S12.6-1984, "Method for the

Measurement of the Real-Ear Protection of Hearing Protectors."

"All EPA data from tests conducted since 1980 will remain valid under a 'grandfather' clause," Smith explained. "Thereafter testing will be required every five years so that at no time will test data be older than five years."

SEI certification of hearing protection devices goes beyond the requirements of the original NRR program established by EPA. Like other SEI certification programs, it includes Quality Assurance Audits of manufacturing facilities. These are conducted periodically by an independent auditor, W.A. Golonski and Associates, to assure that the manufacturer is capable of maintaining consistent quality control in producing hearing protection devices.

Only when both the testing and quality assurance audits are passed will the SEI certification be granted.

The SEI, headquartered in Arlington, Va., is a non-profit operation that exists solely to certify a broad range of safety equipment. Products currently certified by SEI include protective helmets, faceshields, protective eyewear, emergency eyewashes and safety showers.

From the Editor

Dear Fellow AAS Member,

As the editor of *Corti's Organ*, our companion publication to *Ear and Hearing* in the American Auditory Society, I am asking for your personal help. Over the years, I have seen a gradual decline in original material submitted to *Corti's* for publication. This is despite the dramatic rise seen in AAS membership.

I would appreciate your taking a short time on a regular basis to correspond with me regarding clinical or research developments, applications and other activities in your area, of interest to our membership. The format for publication in *Corti's* is more relaxed than typically submitted to other journals. Accompanying pictures or graphs are welcome. As usual, we will be happy to announce future events in *Corti's Calendar*.

Thank you in advance for your time and assistance. I look forward to hearing from you soon.

Sincerely,

Suzanne G. Brown

3M offers training seminar for cochlear implant teams

Training seminars for otologists, audiologists and other clinicians who wish to become involved in cochlear implant practice are being offered by the 3M Otologic Products Program.

The seminars will focus on the 3M Cochlear Implant System/House Design, the only FDA approved cochlear implant. Hearing health professionals who intend to become involved with cochlear implantation programs are urged to enroll in the seminar, which will provide information on: medical evaluation of implant candidates; audiological aspects of patient selection; pre-operative counseling; surgical technique; fitting and adjusting the

device; and post-operative training and rehabilitation.

The seminar will be conducted by 3M with the support and participation of experienced clinicians and audiologists from the House Ear Institute, Los Angeles, and other leading cochlear implant teams from across the United States.

The three-day seminars are scheduled for Nov. 6-9, 1985; Feb. 26-March 1, 1986; June 4-7, 1986; Aug. 6-9, 1986, and Oct. 15-18, 1986.

For a brochure and complete seminar information, write Otologic Products/3M, Department HS85-5, 225-5S-01, 3M Center, St. Paul, MN 55144-1000.

Publication Notice

The *Hearing Aid Handbook* has been reprinted to meet numerous requests for the handbook after the original printing was depleted.

This is a professional and serious layman's guide to understanding, using, maintaining hearing aids and related amplification devices. Contents include: general description of hearing aids, hearing aid components and their functions,

electroacoustic performance of hearing aids, acoustic coupling, hearing aid service and maintenance, special amplification devices and modification, and a special section on understanding the decibel. This text has been considered a "must" for everyone involved in hearing health care, including audiologists, hearing aid specialists and consultants, libraries, students, otologists, hearing and speech centers, universities, colleges, hospitals, governmental agencies, schools for the deaf and hearing impaired, interested parties in hearing aids, and public libraries. The book is 336 pages and includes 224 illustrations.

It can be ordered from:

HUMAN THREE DIMENSIONAL AUDITORY BRAIN STEM RESPONSE

Yvonne S. Sininger
Electrophysiology Lab
House Ear Institute
Los Angeles, CA
John N. Gardi
Coleman Lab
University of California
San Francisco, CA

The auditory brain stem response (ABR) has been recorded from three orthogonal electrode pairs in the horizontal, vertical and anterior-posterior planes. These three channels are then used to create a three-dimensional (channel) Lissajous trajectory of the ABR, termed the 3-CLT. ABR 3-CLTs have been recorded from 10 normal hearing subjects in response to monaural, 70 dB nHL clicks. ABRs from a standard vertex to earlobe montage were recorded simultaneously.

Data analysis included single channel waveform descriptions, analysis of planar segments formed by the 3-CLT, and three-channel amplitude measurements termed "vector amplitude" plots. The X channel, recorded from the nasion to theinion (anterior-posterior) contains low amplitude, early activity with latencies of less than 4 ms. The Y channel, recorded from left earlobe to right earlobe, (horizontal channel) demonstrates large positive peaks with latencies which correspond to waves I and III in the standard configuration. The Z channel, recorded from the vertex to the seventh cervical vertebra (vertical channel) contains activity very much like the standard vertex to mastoid ABR with the exception of early (wave I) activity which is smaller in the vertical channel.

Segments of the 3-CLT have been shown to lie in spatial planes using analysis techniques modeled after vector cardiography. Human ABR 3-CLTs contain 10 planes which overlap in time. The clinical significance of such planes is being investigated.

It is also possible to plot in two dimensions, a representation of 3 dimensional ABR amplitude known as vector amplitude. These plots are created by plotting the voltage length of the vector from the origin to each point along the 3-CLT by time. There are, in general, 7 to 8 peaks in this rectified plot occurring during the first 9 ms (as opposed to the 5-6 peaks of the standard ABR).

Potential clinical and research applications of the 3-D technique will be discussed including a method for determining optimal electrode placement for recording various aspects of the ABR.

ABR RESULTS: RELATIONSHIP TO THE PURE-TONE AUDIOGRAM

Christopher D. Bauch and Wayne O. Olsen
In clinical audiology, ABR tests are used extensively to help differentiate cochlear vs. retrocochlear disorders. However, a variety of contaminating variables must be considered if ABR test results are to be interpreted appropriately. For example, severity and/or slope of peripheral hearing loss can yield abnormal ABR results even though the disorder is not due to retrocochlear pathology.

Because the accuracy of ABR is important in the neuro-otologic evaluation, we have attempted to establish criteria for interpreting ABR test results for various slopes and degrees of hearing loss.

The purpose of this study was two-fold: 1) to examine the influence of audiometric thresholds at 2000, 3000, and 4000 Hz on ABR results; and, 2) to examine the occurrence of abnormal ABR results when various correction factors for wave V latency were used.

Subjects for this study were over 500 adult patients who were referred for ABR evaluations over the past 5 years because of suspected retrocochlear pathology. Of these, 458 (916 ears) were patients found to have no retrocochlear pathology based on medical, audiologic, and/or radiologic evidence. In addition, we evaluated over 40 surgically-confirmed tumor patients. All patients were evaluated by conventional ABR procedures using a three-electrode montage (vertex, ipsi- and contralateral mastoid). Stimuli were 85 or 90 dB nHL clicks (100 microsecond) present at 30/sec.

In general, the chances of observing abnormal ABR results were greater when threshold sensitivity at 3000 Hz was elevated than when 4000 Hz was elevated to a similar degree. Also, the sensitivity at 2000 Hz is important. As 2000 Hz thresholds approached the 65-70 dB range and 3000 and 4000 Hz thresholds were in the 50-70 dB range simultaneously, the percentage of abnormal ABR results increased markedly.

The application of these data to the establishment of correction factors for wave V latency will be presented.

CLINICAL APPLICATIONS OF THE FSP: A NEW TECHNIQUE FOR ON-LINE EVALUATION OF ABR SIGNAL/NOISE RATIO.

Manuel Don
Yvonne S. Sininger
Electrophysiology Lab
House Ear Institute
Los Angeles, CA

Recording of the auditory brain stem response (ABR) involves signal averaging to distinguish the small, time-locked auditory response from random background noise. Clinically, a fixed number of responses are averaged to obtain the ABR based on assumptions about the relative magnitudes of the signal and the background noise. Estimates of signal quality are then made based on replicability of two average responses, usually obtained with the same number of sweeps. However, there is no assurance with this method, that the level of background noise was the same for the two averages.

Recently, Eberling and Don (1984) and Don et al. (1984) have described a method of estimating the relative magnitude of the averaged ABR and the level of background noise which occurred during averaging. They generate an F ratio based on the variance in the averaged response (estimate of signal plus noise) and the variance of a fixed point in each individual sweep (estimate of the background noise). This ratio, termed the FSP, is calculated on-line about every 250 sweeps. Using such a ratio, a probability of the presence of a response can be calculated (for threshold determinations), or the response quality can be quantified.

The current study compared ABRs averaged to specified FSP values with those obtained with fixed numbers of sweeps. The FSP method was found to be clearly superior. In quiet subjects adequate recordings can often be obtained

with fewer sweeps using the FSP and in very noisy subjects, although more averaging is necessary, the averages obtained with the FSP method are consistently cleaner than those obtained with a fixed number of sweeps.

An adaptation of the FSP technique creates a "weighted average" in which blocks of 250 sweeps are weighted according to the level of background noise within the block (Eberling & Wahlgreen, in press). The present study compares this technique to standard artifact rejection schemes. In general, the weighted average was found to be a more efficient method of reducing unwanted noise than conventional artifact rejection.

AUTOMATION IN EVOKED POTENTIAL RECORDING

Aaron R. Thornton
Barbara Sprague Herrmann
and

Janet M. Berrick
Massachusetts Eye and Ear Infirmary
Boston

Evoked response audiometry is, paradoxically, both a labor-intensive as well as a high-tech medical service. Although technologic development has decreased the size and cost of commercial evoked potential systems, the quality of a test result still rests critically with the knowledge and skill of the operator. Interpretation relies heavily on the visual inspection of simple waveform displays and a few arithmetic calculations. Despite the fact that the operator and space overhead are the primary factors in test costs, there has been very little attention to optimizing the equipment for increasing patient throughput or reducing the training level of the operator. To date the human engineering aspects of evoked potential system design are poorly developed. There is insufficient consideration given to how the systems are used in routine service, and the sources of human error in operation are not yet well understood, particularly as they relate to either hardware or software design.

Based on our experience with over 4500 patients seen for auditory evoked response evaluation in an ENT setting, we will identify some of the principal components which determine the basic cost and accuracy of data acquisition and interpretation. We will suggest simple technical improvements which can lower cost and increase effectiveness, particularly for inexperienced clinicians, and identify areas of critical need for future technologic development. The potential for automation will be illustrated by describing the development of a battery-operated, fully-automated, ABR hearing screener which acquires and interprets data without operator control or intervention. It demonstrates that a sophisticated but inexpensive system can be capable of taking over operator functions at low cost without compromising performance. Field testing results for approximately 160 babies will be presented, and both strengths and limitations of automated systems such as this will be discussed.

DIGITAL FILTRATION OF THE AUDITORY BRAINSTEM RESPONSE

William D. Domino, Kevin T. Kavanagh
Memphis, TN

Filtration of the Auditory Brainstem Response (ABR) is necessary to attenuate the energy of unwanted noise yielding the best response with the least number of averages. Analog filters, however, introduce distortion of the response by causing a non-linear phase shift based on the spectra of the individual response components. An alternative is to use digital filtration, and it is the purpose of this presentation to show data representing the effects of distortion in a comparison of filter types.

A digital filtration Fortran program capable of simulating a Butterworth type filter was written and used to evaluate the latencies, amplitudes and morphology of the ABR. The program allowed data analysis with various filter slopes (12, 24 dB/oct.), standard or zero-phase shifting, and 5 Hz step bandpass settings (HP of 0.2-150 Hz, LP of 100-5kHz).

The ABRs of 10 normal adult listeners were elicited to unfiltered click stimuli at 70 dBnHL and recorded with an open filter (BP of 0.2-3kHz) on a Nicolet Pathfinder II system. A vertex to ipsilateral mastoid with contra-lateral ground electrode placement (impedance 3k) was used with the subject resting in a darkened IAC suite. The responses were stored on diskette for later off-line digital analysis.

The results indicate significant differences in the ABR waveform including measured latencies and amplitudes with various BP settings, filter slopes, and phase shift filtering. Phase non-linearity was seen as a major cause of waveform distortion.

Presentation of the results of this study will also include a discussion of distortion as a possible explanation for inter-laboratory differences and the disadvantages, in terms of equipment and time, of digital filtration analysis of evoked potentials.

DIGITAL FILTERING OF AUDITORY BRAINSTEM RESPONSES: A SKEPTICAL APPRAISAL

Roger R. Marsh
Department of Otolaryngology and
Human Communication
The Children's Hospital of Philadelphia

Numerous proposals have been put forth for the use of digital filtering in auditory brainstem response (ABR) recording. It is not clear, however, that any of these is superior to analog filtering, and certain algorithms have serious flaws. I will briefly review the general principles of digital filtering, and its relative merits in ABR testing, then address the limitations of specific approaches that have appeared in the literature. Illustrative examples will be presented, of ABR data which I have subjected to the various transformations.

The arguments for digital filtering methods are that they avoid phase shifting of response components and that they permit great flexibility in filter design, including post-hoc modifications and filter shapes that are not realizable in analog filters. I argue that attempts to apply narrow-band filters of any kind can alter the waveform and that the phase distortion that digital filters can introduce. In particular, digital filters can introduce spurious "waves" that precede the ABR component that elicits them. Other disadvantages of digital filters relate to their computational overhead. Even the readily implemented convolution techniques do involve substantially more computation than does simple averaging, so that the average cannot be updated frequently during data acquisition. More fundamental defects appear in many instances in which the fast Fourier transform is applied without regard to underlying assumptions, with the result of serious distortion.

In the absence of proven merits and abuses, I suggest that digital filtering be used only with caution in research and be avoided in clinical applications.

TRANSDUCER EFFECTS ON THE AUDITORY BRAINSTEM RESPONSE

Daniel M. Schwartz
Department of Otorhinolaryngology
Human Communication
University of Pennsylvania School of
Medicine
Philadelphia, PA

continued on page 4

continued from page 3

Kathy Goodman
Main Line Audiology Associates
Ardmore, PA
Grant A. Berry
Noreen Daly
and
Kristine Olson
Hospital of the University of Pennsylvania
Speech and Hearing Center
Philadelphia, PA

In routine ABR testing the brief duration rectangular wave electric pulse is transduced through some type of standard electrodynamic audiometric earphone (e.g. TDH-39; TDH-49) housed either in circumaural or supraaural cushions. Since these electrodynamic earphones have low input-load impedance they often impart stray electromagnetic fields which are passed through the recording electrodes often resulting in contamination of the early portion of the ABR. When this electromagnetic artifact is coupled with the "ringing" often associated with insufficient damping of the earphone response, it minimizes the ability to visualize wave I or has a compromising effect on wave I morphology. The importance here, of course, is that wave I serves as the electrophysiologic bench mark of the distal portion of the VIII nerve and is critical to neuro-audiologic diagnosis.

Recently, two new types of air conduction transducers have been introduced to help alleviate the problems of electromagnetic artifact to enhance greatly the amplitude of wave I. The first is a piezoelectric earphone transducer having electrostatic shielding and the second is a new insert earphone designed by Killian, which is thought to produce a roughly rectangular pressure pulse at the eardrum without excessive ringing. The former is excellent for use in the clinical electrophysiological laboratory whereas the implications for the insert transducer are greatest for intra-operative monitoring of the ABR.

We wish to report our experiences with these two types of air conduction transducers as compared to standard electrodynamic audiometric earphones both in terms of electrodiagnostic and intra-operative recording of the auditory brainstem response.

Results will be discussed relative to normative data for latency, amplitude and waveform morphology across transducers. Normative findings will be compared to a series of patients with surgically confirmed lesions in the posterior fossa.

COCHLEAR NUCLEUS IMPLANTATION: CLINICAL RESULTS

Laurie S. Eisenberg
J. Phil Mobley
Franco Portillo
House Ear Institute
Los Angeles, CA

Electrical stimulation of the ventral cochlear nucleus in the brainstem has been documented in a female adult deafened by bilateral acoustic neuromas. The electrode was surgically placed at the time of the second tumor removal. She has now been receiving direct electrical stimulation via an analog processor and percutaneous coupling for over 4 years. In the past year, two more adults have received cochlear nucleus (CN) implants following removal of the second tumor. For these two subjects, the percutaneous connection has been coupled with the standard signal processor currently being used with scala tympani (ST) cochlear implant patients - the 3M/House 16kHz amplitude modulated processing scheme. A clinical program has been established for patient testing, device fitting and rehabilitation

using an engineering/audiology team.

Clinical data being collected for the CN implant project includes both electrical and sound field measures. Electrical measurements include thresholds, uncomfortable loudness levels (ULL), and tone decay testing at frequencies 250, 500, 1000, 2000, 4000, and 16000 Hz. Measurements are recorded according to current, impedance, and voltage levels. Soundfield measurements include warble tone thresholds across the frequency range of 250-4000 Hz, speech detection thresholds, ULL for speech, the Monosyllable-Trochee-Spondee Test, Environmental Sounds Test, and the Speech Pattern Contrast Test.

Test results collected on the three implanted subjects indicate fluctuations in electrical measurements over time, particularly in the first months following surgery. Tone decay testing indicates an ability to sustain tone perception for one minute at all frequencies tested. Auditory soundfield thresholds measured through the signal processor tend to be poorer than what is typically seen for ST implant users. Auditory discrimination scores on closed-set tasks indicate an ability to encode suprasegmental information, comparable to what is seen for ST implant users. The CN implant subjects use their devices on a consistent daily basis, and report benefit similar to what is reported by ST implant users.

Cochlear nucleus implantation is proving to be a viable alternative for totally deaf individuals who cannot benefit from ST cochlear implants. Immediate goals for this project include: 1) setting up clinical trials under FDA guidelines, and 2) determining feasibility for transcutaneous transmission of signals using different processing schemes.

EXPLANATION AND REIMPLANTATION OF A MULTIELECTRODE ARRAY IN THE SAME EAR

Dianne J. Mecklenburg,
Judith A. Brimacombe
Cochlear Corporation
Boulder, CO

Richard C. Dowell, Graeme M. Clark
University of Melbourne
James F. Patrick
Nucleus Limited

Major controversy surrounds the issue of cochlea damage due to implantation of electrodes for the restoration of hearing sensation. However, successful explantation and reimplantation of a free-fit, 20-banded multielectrode array has been demonstrated in three patients with no degradation in behavioral responses. For these cases, the original University of Melbourne multielectrode array was surgically implanted, then removed five to six years later when a Nucleus multielectrode array was reimplanted in the same ear. During both surgical procedures, no complications occurred in any case. Comparable current thresholds, effective dynamic ranges, place-pitch rankings and other psycho-physical measurements were obtained following the first and second surgeries. Speech discrimination testing revealed that patient's performance continued to improve with time, following the second surgery, and psycho-physical measurements remained stable. These findings demonstrate the feasibility of explantation and reimplantation of this free-fit, banded multielectrode array.

METHODOLOGY TO FIT OUR TECHNOLOGY: THE DEVELOPMENT OF AN AUDITORY THERAPEUTIC PROGRAM FOR YOUNG PROFOUNDLY HEARING IMPAIRED CHILDREN.

Charles A. Gammel
Jackson, MS

For at least the last one hundred years there have been sporadic efforts to develop therapeutic methodologies for persons

with severe hearing losses which would utilize acoustic signals presented to the ears. Although each of these efforts met with some success their limitations are easily measured by their lack of general acceptance. For most profoundly hearing impaired people the development of these methods had little or no impact. In the last two decades of the twentieth century, however, practitioners of the hearing sciences find themselves in a position to apply newly developed technological aids with newly developed methodology. For example, the development of extremely powerful, very small head worn hearing aids with relatively broad frequency response and good fidelity now makes it possible for us to fit very young children with true binaural aids and achieve conditioned responses to sound. Lagging behind have been the therapeutic programs to shape these responses into meaningful communicative behaviors.

This paper reports on the development of one such therapeutic programs and its results over a five-year period of operation. The subjects of this investigation were young profoundly hearing impaired children enrolled in special classes before age three, fitted with high gain amplification and trained in the use of the acoustic output of their hearing aids as their primary source of information. This paper will report on the gradual evolution of a therapeutic regimen and its results. Comparisons will be drawn between the functioning of children in various phases of the program's development and between the subjects as a group and other children in more traditional oral and non-oral environments.

A WEARABLE MULTI-CHANNEL ELECTROTACTILE SENSORY AID FOR THE DEAF

Barbara Franklin
San Francisco State University

There have been numerous attempts to develop tactile sensory aids beginning with Gault in 1926. This paper will focus on the use of electrocutaneous stimulation to deliver information to the tactile system. Tactile sensations are produced by directly stimulating the nerve endings in the skin with brief pulses of electricity, yielding a vibratory sensation which is reliable and painfree. Electrotactile sensory aids present acoustic information to the skin via a belt of stimulators worn around the abdomen. Each stimulator responds to a specific pitch; low frequency sounds are represented on one end of the belt, and high frequencies are represented on the other end. A siren sound, rising and falling in pitch, is perceived as a sensation moving left and right around the abdomen. Speech sounds are perceived as dynamic, moving patterns, corresponding to the sound frequencies present in the utterance.

The "Teletactor" developed by Dr. Frank Saunders and his associates (1974) is a 32-channel non-portable electrotactile aid which displays sound ranging from 80 - 8000 Hz on a belt worn on the abdomen. The first field evaluation of the "Teletactor" was conducted during Spring 1978 (Saunders, F., et al., 1981). The belt was tested for comfort, reliability, and speech recognition with six children with profound sensorineural hearing loss, 5-8 years of age. Following a period of training, all children demonstrated the ability to discriminate number of syllables, duration and intensity patterns of utterances, pitch changes, and voiced/voiceless fricatives. A specific speech training program was implemented with the "Teletactor" from 1979-81 with three profoundly deaf children (Franklin, B. and Saunders, F., 1981). There was an increase in speech intelligibility for each child. A pilot study was conducted in 1979 to investigate the effect of the "Teletactor" on the speech of

four deaf-blind children in the California School for the Blind. The children demonstrated increased vocalization as well as improved voice quality and speech rhythm.

A wearable 16-channel electrotactile sensory aid designed to supplement information obtained through lip-reading and/or residual hearing is currently being evaluated on six profoundly deaf children, 3-7 years of age, from the Jackson Hearing Center in Palo Alto, California. The device consists of a lightweight belt worn under the clothing against the skin of the abdomen, connected to an electronic enclosure approximately the size of a Sony Walkman stereo, which in turn receives audio input from a microphone and power from a small battery pack. This paper will discuss the development of the device, the test battery used to assess communication skills of the project children, the training program designed to teach them how to interpret the tactile information, and the effect of the tactile aid on their receptive and expressive communication skills. Plans for field testing the device on deaf/blind children will be presented. A wearable electrotactile sensory aid should enhance the development of communication skills and auditory awareness by providing the child with continuous feedback of his/her own speech, the speech of others, as well as sounds in the environment. This research is currently being supported by an NIH Small Business Innovation Research Grant.

DEVELOPMENT OF INSTRUMENTATION AND PROCEDURES FOR DETECTION OF PERILYMPH FISTULAS

David J. Lilly, F. Owen Black
and **Lewis M. Nashner**
Good Samaritan Hospital
and Medical Center
and
Neurological Sciences Institute
Portland, OR

Lucae (1881) probably was the first to describe conjugate deviation of the eyes, objective nystagmus, loss of balance, spatial disorientation and nausea for a patient when air pressure in his middle ear was made higher or lower than ambient. When this pneumatic test is positive, the results usually are reported as a "positive fistula sign." In our experience, perilymph fistula also is an important cause of sensorineural hearing loss. Unfortunately, over the last 100 years, there has not been a simple, non-invasive test for diagnosis of perilymph fistulas.

In this presentation we shall describe the development of instrumentation and a test procedure for quantification of the fistula test. We also shall describe our clinical findings with this procedure. Our approach is based upon vestibulospinal responses to variation in air pressure within the external auditory meatus (EAM). More specifically, during the test, a patient stands on a moving-platform system (Nashner, 1977). With this system we can remove systematically his visual and support-surface references (Fig. 1). This leaves the patient with only vestibular control for his orientation in space (Fig. 2). A commercial aural acoustic-immittance system is used to change air pressure in the patient's EAM. To date, all patients with surgically confirmed perilymph fistulas have demonstrated a reproducible phase-locked sway in response to sinusoidal air-pressure changes (Fig. 3).

This paper will focus upon a progression of instrumentation approaches for quantification of the fistula test. The first (Phase I) approach involves a simple personal-computer peripheral to monitor the patient's sway. The second (Phase II) approach requires a force platform to

continued on page 5

continued from page 4

monitor the patient's torque and center of pressure in addition to sway. The third (Phase II) approach utilizes the moving-platform system described above. These three approaches will be evaluated in light of fistula-test results from 150 patients.

ABR RESULTS IN PATIENTS WITH POSTERIOR FOSSA TUMORS AND NORMAL PURE TONE HEARING

Frank E. Musiek
Nathan A. Geurkink
Section of Otolaryngology and Audiology
Department of Surgery
Dartmouth-Hitchcock Medical Center
Hanover, NH
Ann Forest-Josey
Michael E. Glasscock
The Otology Group
Nashville, TN

It is commonly acknowledged that tumors in the posterior fossa result in pure tone hearing deficits. Though it is rare, there are exceptions to this trend. We have collected 16 patients with normal pure tone hearing and space occupying lesions of the eighth nerve, cerebellopontine angle (CPA), or brainstem region.

The auditory brainstem response (ABR) was conducted on all patients. The ABR was done in a conventional manner using high intensity click stimuli (80 dB n HL, 15/sec). All waveforms were replicated to ensure consistency and validity.

ABR data was analyzed with regard to absolute and interwave latencies, as well as interaural latency difference (ILD) and presence or absence of waves I, III, and V. Other information such as primary symptomatology, tumor size and site, and additional audiological information was also analyzed.

The results indicated some interesting trends. In some instances, posterior fossa lesions — many of them large — may not affect pure tone hearing sensitivity. Our 16 patients with normal pure tone sensitivity were obtained from a pool of 68 patients with posterior fossa tumors. These patients' primary symptoms encompassed a broad and varied spectrum of type and severity, the most common being hearing difficulty despite normal auditory sensitivity. Of the various latency measures, the ILD and the absolute indices were the most valuable indicators of a disorder. The interwave measures were highly accurate for detecting abnormality but could not be computed for many subjects due to the absence of waves. For example, the I-V interwave interval could be measured in only 7 of the 16 subjects.

One ABR from this group was normal for all measures considered, while in two cases, no auditory brainstem response could be obtained. Interestingly, these two cases represented the two smallest tumors.

Detailed statistical information on the above results and case profiles will be presented.

AUDITORY BRAINSTEM RESPONSE SPECTRAL CONTENT IN SEVERELY HEAD-INJURED PATIENTS

James W. Hall III
Denice P. Brown
Susan M. Tompkins
Judy Mackey-Hargadine
Lincoln Gray

There is a modest literature on the spectral, or frequency, composition of the auditory brainstem response (ABR) in persons with normal hearing and normal central nervous system (CNS) status. To our knowledge, there are no published reports describing the ABR spectral content of patients with CNS pathology. The purpose of the present study was to compare the patterns of ABR spectral content

for normal subjects vs. patients with severe head injury, in an attempt to assess the potential clinical value of ABR spectral analysis.

Fig. 1 SPECTRAL CONTENT

METHOD

There were twenty normal subjects (Group I) and four groups of acute, severely head-injured subjects (20 subjects per group). Head injury groups were as follows: normal ABR latency values, alive at 2 weeks post injury (Group 2); normal ABR latency values, dead at 2 weeks post injury (Group 3); abnormal (greater than 4.6) msec ABR wave I-V value (Group 4); only a wave care unit with commercially available equipment, according to standard clinical protocol, spectral analysis was carried out with Nicolet Pathfinder II software.

RESULTS

A representative normal ABR waveform and its power spectrum is illustrated in Figure 1. Three main frequency components are evident. Low frequency (300 Hz and below) energy predominates, but there are also distinct spectral energy bands in the 500 to 600 Hz and 900 to 1000 Hz regions. As displayed in Figure 2, this was

the typical normal frequency composition pattern. Often there was an additional peak of minimal power in the 1200 to 1400 Hz region. In contrast, comatose head-injured patients usually showed little or no high-frequency (above 500 to 600 Hz) energy, even those patients with ABR absolute and interwave latency values well within normal limits. Indeed, for many of these patients, spectral energy was limited to the lowest frequency (300 Hz and below) region. Patients with a wave I component only invariably did not have evidence of high frequency ABR energy.

CONCLUSIONS

Spectral analysis of the ABR in normal subjects and persons with CNS pathology is clinically feasible with commercially available equipment. Spectral information appears to supplement traditional ABR analysis parameters, such as wave component latency and amplitude measures. A group of 40 severely head-injured patients with a normal ABR by latency measures had markedly different ABR power spectrums, in comparison to an age and sex matched control group. Guidelines for clinical application of ABR spectral analysis will be outlined.

COCHLEAR OTOSCLEROSIS: PATIENT PROFILES AND AUDIOLOGIC FINDINGS IN 150 CASES

Brian D. Forquer
James L. Sheehy
Otolitic Medical Group, Inc.
Los Angeles, CA

Examining the patient histories and audiological findings of cochlear otosclerosis patients over the past five years, we have been impressed by the heterogeneity of the group. This paper reviews the patient histories and audiological profiles of 150 patients who were diagnosed as having cochlear otosclerosis by polytomography.

The dimensions of patient history which were examined were: 1) Age 2) Sex 3) Duration of hearing loss 4) Family history of hearing loss or otosclerosis 5) Was the patient ever dizzy? 6) Was the loss progressive? 7) Did the patients have tinnitus? Audiologic findings which were assessed included: 1) Impedance results 2) Magnitude of hearing loss 3) Magnitude of air-bone gap 4) Speech discrimination 5) Slope of audiogram 6) Electronystagmographic findings 7) Auditory brainstem response findings.

Results of this study indicated that it is common for patients with cochlear otosclerosis to have mild to moderate sensorineural hearing losses with excellent speech discrimination. Age and slope of audiogram were two dimensions which we have expected to be predictable and were not. Acoustic reflex findings and auditory brainstem response findings are reviewed in some detail. Of the 282 ears tested in this study with reflex audiometry, 215 (76%) had reflex findings suggestive of minimal stapes fixation.

EFFECTS OF OTOTOXIC DRUGS AND AUDITORY EVOKED POTENTIALS IN MONKEYS

John T. Jacobson
John A. Bedford
W. Alan Eisele
Beverly Turner
Department of Communicative Disorders
The University of Mississippi
University, MS

Although it is well known that certain drugs and drug classes such as acetylsalicylic acid, aminoglycoside antibiotics and loop diuretics are toxic to the auditory and vestibular system, basic pharmaceutical research has not routinely involved testing for ototoxicity. The primary rationale has been that the condi-

tioning techniques available for animals were expensive and time consuming with little means of validation. However, with the advent of microcomputer-based systems for measuring auditory evoked potentials, screening for ototoxicity is now economically feasible, objective and far more accurate than previous techniques.

The use of marijuana and cocaine is pervasive in today's society. The social, economic and psychological ramifications have been well documented. However, a paucity of information exists with regard to the effects of cocaine and delta-nine tetrahydrocannabinol (THC), the active compound in marijuana, on the auditory system (Caldwell et al., 1969 a and b; Liedgren et al., 1974, 1976; Thaler et al., 1973). Research has been confined for the most part to behavioral protocol with limited electrophysiological evidence. With this in mind, the purpose of this paper is to discuss the effects of THC and cocaine on the auditory mechanism in monkeys as measured by the auditory brainstem responses (ABR).

METHODOLOGY

Fourteen stump-tailed macaque monkeys (*M. acrotydes*) with an average weight of about 11 kg. were used in this experiment. Monkeys were selected due to their availability at the University Primate Center and their relationship to man on they phylogenetic scale. Initially, human subjects were considered, however, due to ethical and moral questions raised by the University's ethic committee, humans were precluded from participation.

Marijuana and cocaine were obtained through grants from the National Institute on Drug Abuse. Preliminary preparation was identical to that described in our companion paper. Briefly, monkeys were anesthetized with Katamine HCl (IM) with supplemental administration of diazepam (IM). Electrodes were attached to the vertex, and earlobes bilaterally. During testing, each monkey was administered a 1.0 mg/kg IV dose of THC dissolved in 0.5 ml of absolute ethanol followed immediately by ABR testing. In a second testing series, monkeys were injected IV with a 1.0 mg/kg dose of cocaine HCl in sterile distilled water. ABR tracings were recorded and after a return to baseline, a second injected IV with 3.0 mg/kg cocaine HCl was given followed by ABR.

ABRs were recorded with a Bio-logic Computer. Monaural click stimuli were presented to the right ear of each monkey at a rate of 11/sec. A bandpass setting of 100 to 1500 Hz was used and a 10 msec analysis window. Intensity was maintained at 80 dB nHL (re: humans) for all testing sessions.

Upon administering of THC, body temperature decreased to 34 C. Because a reduction in temperature will compromise the ABR, a warming blanket was placed beneath each monkey to maintain normal body temperature. Cocaine did not alter temperature. The results of IV injected THC and Cocaine prolonged the absolute and relative latency patterns of the ABR tracings. Abnormally prolonged responses were seen for both peripheral and central measures. This degradation implies that the neural generators of the compound cochlear action potential and caudal region of the brainstem were affected by induced toxic effects of marijuana and cocaine. A rationale is built for further electrophysiological study of these drugs and in the general area of neurotoxicology. Further, the implications of drug administration under acute and subchronic conditions and their relative clinical applications are discussed.

PRELIMINARY FINDINGS ON THE EFFECTS OF TENSOR TYMPANIC TENOTOMY ON ACOUSTIC REFLEX LATENCY AND AMPLITUDE

Robert E. Moore and Michael Stuss

Traditionally, acoustic reflex threshold, and/or decay have been used in the diagnosis of audiological, otological, and neurological disorders. Recently, more subtle measurements, including reflex latency and amplitudes, have been developed in an attempt to enhance these diagnostic capabilities. Since reflex latency and amplitude are dependent on the integrity of the entire reflex system, it is conceivable that lesions involving the tensor tympanic muscle and/or the trigeminal nerve could alter the results of these movements. The purpose of this study was to investigate the effects of complete tensor tympanic tenotomy on acoustic reflex latency and amplitude.

Twelve adult, mixed-breed dogs were utilized in the study. The dogs were divided into two groups. Six dogs were subjected to surgical transections of the tensor tympanic tendon, and 6 dogs were used as Sham-operated controls. Pre- and post-surgical measurements of contralateral and ipsilateral acoustic reflex and latency and amplitude were made on each dog using a stimulus frequency 1 KHz and 2 KHz. Stimulus intensity ranged from 70-110 db KHz for ipsilateral reflexes and 120 db KHz for contralateral reflexes. Tympanometry and static compliance measurements were made prior to each recording session to insure that no changes in the middle ear system had resulted from the surgical procedure.

Post-tenotomy measurements showed no significant change ($P > 0.05$) in latency or amplitude for either contralateral or ipsilateral reflex at 1 KHz or 2 KHz. From these results it appears that the tensor tympanic reflex system has no significant role in acoustic reflex latency and amplitude and that lesions to that system are not reflected as changes in these two reflex parameters.

NEW NOISE SUPPRESSION TECHNIQUES USING REAL-TIME DIGITAL FILTERS

James A. Nunley and Wayne J. Staab

The use of digital signal processing in audio is fairly widely accepted. There was some controversy for a time about the quality of sound produced by this technique. The use of laser discs and other techniques have put the problem of quality to rest. We can therefore expect digital processed audio to be of high fidelity. The obvious reason to consider digital signal processing is for signal enhancement. The main problem hearing impaired have with present audio signals is noise interference. To eliminate the noise and retain the signal, is the goal. The signal, in most cases for the hearing impaired, is speech. Speech occurs in real-time, i.e., the word is spoken and the listener receives the sounds almost instantly. The goal then is to analyze the signal, determine what is needed and what is to be discarded. There are presently available microprocessors that are fast enough to perform this real-time processing. The significant feature is to instruct the microprocessor what to do. Various mathematical instructions can be written to direct the microprocessor how to manipulate the signal. These mathematical instructions are called algorithms. The algorithms that seem to hold the most promise are ones that look at the signal and make real-time adjustments or adaptive filtering. We are presently looking at several different approaches to real-time adaptive filtering.

One approach is to sense the overall signal level, measure the low-frequency content, and adjust the amplifier compression ratios in various frequency bands. A second approach is to analyze the overall signal level, measure the various spectrum components, and adapt the compression ratios to various bands.

A third approach, and one that shows much promise, is the near field, far field approach. This method teaches the microprocessor to control on the near signal, i.e., the speaker, and reject the far field, i.e., the noise.

The presentation will demonstrate these various techniques through tape recorded messages.

VIRTUAL INSTRUMENT METAPHORS FOR CLINICAL HEARING SCIENCE

David J. Lilly

Good Samaritan Hospital and Medical Center

and

Jonathan D. Birch
Virtual Corporation
Portland, OR

Formal training and professional experience have produced generations of audiologists, otolaryngologists and hearing-aid specialists who are familiar with the front panel layout and control of analog instruments. These same individuals, however, have been reticent to adopt personal computers for clinical applications. Much of this reluctance can be traced to inappropriate interfaces between the human operator and the computer. Command-driven software, menu-driven software and keyboards simply are not efficient for most clinical tasks.

In this presentation we shall describe an extension of the virtual device interface concept to requirements in clinical hearing science. More specifically, we have developed hardware and software solutions that simulate the control panel and the graphic output of an analog instrument on the video display of a personal computer. Initiation of a desired test or procedure is accomplished by pointing to a "virtual control" with a "mouse" or a "track ball" and then selecting (clicking on) that function. Interruption of a test, termination of a procedure, plotting of results, changing scales and outputting "hard copy" all can be accomplished by displaying the appropriate icon on the display. Most tests can be completed without the keyboard.

We are using the term VIRTUAL INSTRUMENT METAPHOR (VIM) to describe this stimulation of an analog instrument. Initial development of this approach has been implemented on a Macintosh computer. Thus, it represents an extension of the "virtual desktop metaphor" provided with that machine.

That attached (supplemental) figures provide a graphic overview of our VIM interface for computers in the clinic. The example is for an aural, acoustic-immittance system. When the program is run, the first display (Fig. 1) resembles the front panel of an analog instrument. The "virtual needles" on the "virtual analog meters" indicate the approximate quantities and trends while the actual values appear below each meter. The user simply moves the pointer to the desired "virtual control button" and selects it. Figure 2 depicts a tympanometry and Fig. 3 shows the resulting display. These examples will be expanded with clinical results during the presentation.

USING PHYSIOLOGICAL PROCESSES TO SUPPLEMENT HEARING PROTECTORS

David M. Lipscomb

University of Tennessee, Knoxville

Hearing protectors have historically been found to offer better protection in

continued on page 7

FIG. 1

FIG. 2

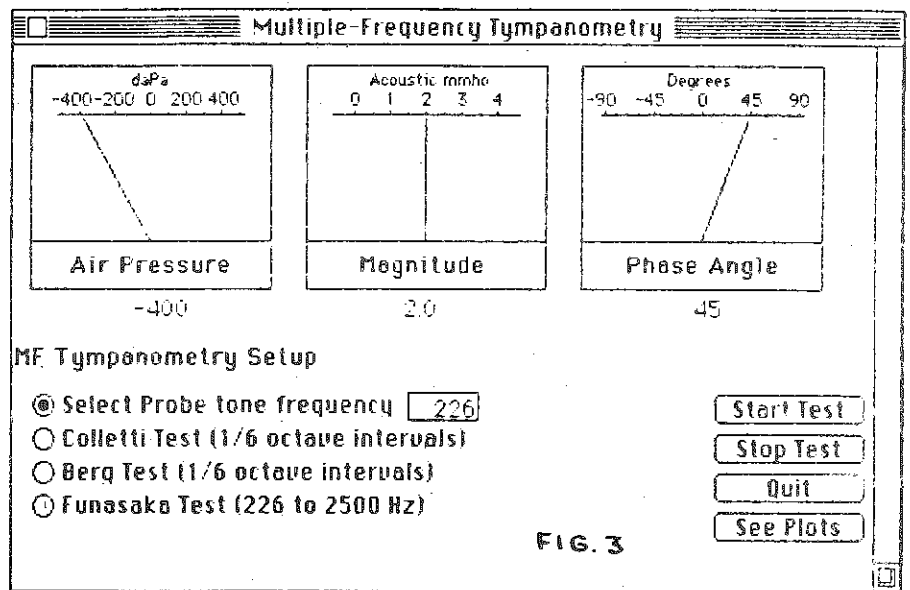

FIG. 3

continued from page 6

laboratory measurements than in the field. It is therefore desirable to supplement or complement hearing protector use and attenuation ability if possible. A series of experiments using Carbogen (95% O₂ & 5% CO₂) or compressed air with 5% CO₂ added have indicated in human and animal subjects that inhalation of either gas before, during or after noise exposure that residual effects are reduced. Because logistical problems would be caused by the attempted use of large "oxygen tanks" and requisite valves, a more direct method of introducing CO₂ to the breath stream in controlled doses has been developed. This paper discusses that system and proposes a research protocol to evaluate this "physiological hearing protection" process in the field as a potential means of augmenting the use of hearing protective devices where conventional protectors have been found to be inadequate or to provide a degree of protection in cases of accidental exposure. The value of this approach is that it uses normal physiological means to decrease individual susceptibility to NIPTS rather than to rely on the introduction into the body of a pharmacological agent with possible side effects. Other applications to hearing conservation such as increasing the rate of recovery from TTS, and use in reducing TTS contamination of industrial hearing test results will be reviewed.

SIMULTANEOUS MULTIFREQUENCY TYMPANOMETRY USING FOURIER TRANSFORMS OF BROAD-BAND NOISE

Vernon D. Larson

Athens, GA

and

Christopher Ahlstrom

Audiology and Speech Pathology

VA Medical Center

Augusta, GA

Conventional tympanometry using low frequency probe-tones has proven to be relatively insensitive to pathologies involving the ossicular chain. Current understanding of the physical characteristics of the middle ear and the measurement of acoustic impedance at the lateral plane of the tympanic membrane suggests that the diagnostic sensitivity of tympanometry would be improved through the use of higher frequency probe signals.

The purpose of this paper is to describe a new method of multi-frequency tympanometry and to provide a normative data.

A broad band noise was delivered to ears using a standard admittance probe assembly under dc pressure conditions from -400 to +200 dPa. The noise was monitored using a miniature microphone in the probe assembly and was passed to analysis equipment which performed the Fast Fourier transform. The result of the transform and subsequent statistical manipulations produced a family of 300 tympanograms in the frequency range from 200 to 4000 Hz for each ear.

Results on normal patients were analyzed and plotted in a three-dimensional array, (frequency-by-dc pressure-by-impedance). When viewed in this way

significant differences between normal male and female subjects were apparent. Results also show distinct morphological changes as a function of frequency. Comparison of these normative data to ears with ossicular disorder will also be presented.

Work supported by the Veterans Administration.

PRESSURE IN THE TRAVELING WAVE AND THE ELECTROMODEL

George C. Offutt

Gold Center of Sensory Processes

Shepherdstown, WV

Stimuli were presented simultaneously to the chinchilla cochlea through the external meatus and the scala tympani so that displacements of the basilar membrane were controlled by dual pressure waves. Changes in the phase relationships of these pressure waves influenced the CM amplitude but often had little influence on the compound action potential. The N amplitude was apparently a function of the summed energy in the two stimulus inputs and was often independent of the phase difference between the two pressure waves. Thus, the mechanical displacements of the basilar membrane may not be the only source of energy for hair cell transduction in the cochlea.

The possible sensitivity of the cochlea to the pressure component of the traveling wave requires a rethinking of the entire field of auditory research. It is possible that interpretations of all auditory research have been based upon a false assumption. It may be that the inner hair cells (IHC) are not mechanoreceptors but are primarily sensitive to electrical potentials. The tectorial membrane may be piezoelectric and perform the initial transduction of energy in the pressure wave into electrical potentials that are detected by the IHC. There is biological basis for proposing each of the transduction steps. The concept of electrosensitivity by the IHC provides the basis for a new view of the auditory system as presented in a recently published book *The Electromodel of the Auditory System*.

THE ELECTROMODEL OF THE AUDITORY SYSTEM

George C. Offutt

Gold Center for Sensory Processes

Shepherdstown, WV

It is obviously a desirable goal to be able to relate all experimental observations of cochlear function to each other within one unified theoretical framework. The electromodel is a holistic model that is the basis of a unified view of how the cochlea and other organs of hearing function. The preponderance of evidence may appear to support the assumption that all cochlear HC are sensitive to mechanical stimuli - this assumption will be questioned.

The basis of the electromodel of cochlear function is a dual-transduction of acoustic stimuli. Thus, in addition to the mechanical stimulation of the outer hair cells (OHC), the pressure in the traveling wave is apparently transduced by a piezoelectric tissue (i.e. tectorial membrane) into electrical potentials. The inner hair cells (IHC) may then detect the electrical potentials present at their cuticular surfaces. This proposal negates the problems of submolecular transduction of mechanical stimuli near threshold and the origin of the tuning observed in the primary neurons. Evidence will be presented to show that the cochlear pressure wave may be an effective source of energy.

Possible explanations for several cochlear phenomena will be presented that are based on the electromodel and its proposition that the IHC are electroreceptors.

Tinnitus: The electrosensitive IHC are apparently responding to brain potentials after suppression is decreased due to the loss

of OHC.

Hearing Loss: The first 30 to 40 dB of permanent hearing loss may be due to a repositioning or pull-up of the tectorial membrane that would result in a decreased amplitude of effective stimuli to the IHC near threshold.

Cochlear Prosthesis: After a severe hearing loss, remaining IHC would be more effectively stimulated by placing the electrodes of the prosthesis in the scala media. This will probably result in an improved frequency discrimination.

"Distortion Products": The cochlear microphonics (CM) from the OHC are sensed by the IHC at relatively high stimulus intensities. When CM are evoked by more than one frequency of stimulation, the resulting combination potentials are sensed by the IHC at a new frequency.

Is it possible that the entire field of auditory research is built upon a false assumption? I propose that we consider the inner hair cells (IHC) not primarily mechanoreceptors but electroreceptors. Although, the outer hair cells (OHC) are undoubtedly stimulated mechanically, there is no proof that IHC are also sensitive to mechanical stimuli. Thus, I question the assumed IHC response to mechanical stimuli.

Conditions may be similar to those in the story by Robert Louis Stevenson. Everyone knew Dr. Jekyll and all were quite surprised when the personality of Mr. Hyde surfaced. The one character had two dispositions and each surfaced at different times. You may be similarly surprised when I discuss the dual capabilities of cochlear hair cells. Suga (1967) showed that certain lateral line hair cells (HC) were capable of detecting both electrical and mechanical stimuli. Although each type of HC was sensitive to both modalities, certain HC were more sensitive to electrical potentials than to mechanical stimulation. It may be that the IHC are primarily electroreceptors that are sensitive to mechanical stimuli only at high stimulus intensities.

There is increasing evidence that the cochlear hair cells interact in some way. Such a relationship is necessary to explain certain of the nonlinearities, reactions to multiple tones and sensitivities. Most proposals employ some mechanical interaction such as a cochlear amplifier, waves in the tectorial membrane or movements by the hair cells. However, a few investigators have proposed some form of secondary electrical communication in addition to the fundamental mechanical sensitivity of the hair cells.

Today I want you to consider how the field of auditory research looks after the assumption is made that the IHC are primarily sensitive to electrical potentials. The recently published book *The Electromodel of the Auditory System* is that view of the auditory system after the assumption of electrosensitivity by the IHC was made. The electromodel has three principal parts. None of these parts is especially unique and all have been suggested at some time to have a role in sound detection. However, these three concepts have never been juxtaposed in one model.

First, let's assume that the IHC are electroreceptors. There is no negative evidence to controvert this assumption and certain HC do possess this property. In the lateral lines of fish there are HC that are sensitive to potentials as low as 1-10 uV. Many experiments have shown that cochlea are responsive to electrical potentials, but it has always been assumed that the potentials generate a movement that is then sensed (i.e. electrophonics). I am proposing that such an electromechanical transduction is not always necessary.

Second, if the IHC are electroreceptors, what is the source of their stimuli? That is, where do the potentials come from? In

crystal microphones, piezoelectric materials provide potentials that follow the characteristics of the sound stimulus. In fish, the ear stones of otoliths have been shown to be highly piezoelectric; and I have proposed that the otoliths may provide potentials that function in sound detection (Offutt, 1974). In the cochlea the tectorial membrane is analogous to the otoliths and may supply piezoelectric potentials to the IHC. All biological tissues are piezoelectric; thus, the question to consider concerns the level of piezoelectricity that the tectorial membrane may possess. This unique acellular tissue has been studied extensively but I know of no reports as to its piezoelectric properties.

Third, the pressure component of the traveling wave stimulates the piezoelectric tectorial membrane to generate the potentials that are detected by the IHC. It is widely assumed that the cochlear pressure is not an effective stimulus. However, this assumption has never been properly tested. Wever and Lawrence (1950) came closest to a test when they presented dual stimuli to the cochlea through the external meatus and the round window (RW). However, they only measured the cochlear microphonics (CM) and then showed that the pressure component of the stimulus did not influence the CM and therefore had no influence on hearing. The assumptions have been questioned that the CM is a receptor potential or is a component in the sequence of events leading to the detection of sound. If the CM is not an indicator that sound detection is occurring, then the experiments of Wever and Lawrence (1950) are not conclusive relative to the importance of pressure in the cochlea.

Preliminary evidence based upon compound action potentials (CAP) indicates that the pressure wave in the cochlea is the effective stimulus for stimuli that are close to threshold. Dual stimuli were presented to the cochlea of chinchillas through the external meatus and the scala tympani. The phase of these dual stimuli could be adjusted to null and the CM recorded at the RW by an average of 17dB. This is due to the variation of the displacement of the basilar membrane (BM) as the phase between the pressure waves in the two scalae was changed. When the stimuli were in phase, there was little or no movement of the BM and a minimum of CM were evoked. Also, when the stimuli were out of phase there was a maximal amplitude of CM. These results are similar to those of Wever and Lawrence (1950).

However, the phase between the stimuli in the two scalae had no effect on the amplitude of the CAP. This was true both when the CM were nulled or were double in amplitude relative to a single channel of input. Thus, the pressure in the stimulus seemed to be the principal component involved in the activation of the primary neurons.

In summary, I am proposing that the pressure component of the traveling wave activates the tectorial membrane to generate piezoelectric potentials that are sensed by the inner hair cells. This may be the primary mechanism leading to sound detection near threshold while at higher stimulus levels other processes become more important.

There are several aspects of this model that are especially interesting and potentially valuable. With the electromodel, there is no need to propose a threshold stimulation by a subatomic movement of the basilar membrane upon which the hair cells reside. Interactions between hair cells (e.g. "distortion products" and suppression) become a fundamental aspect of the electroreception by the inner hair cells. The secondary mechanical events

(e.g. acoustic emissions) that are often observed may be explained on the basis of electromechanical transduction in the piezoelectric tectorial membrane.

In the clinic, several distinct levels of deafness may be defined and treated. Initial deafness may be due to the pull-up or repositioning of the tectorial membrane that would result in a decreased amplitude

of the potentials available to the IHC. Tinnitus may be due to the hypersensitivity of the IHC after the loss of OHC suppression. Thus, tinnitus may be thought of as the subject listening to himself think. That is, tinnitus may be when the IHC are responding to potentials from the brain. It is possible that the use of cochlear prostheses may be improved by placing stimulating electrodes in the scala media where a more effective stimulation of the IHC will be achieved.

Assistive devices catalog ready

Sound Resources, Inc., a firm specializing in amplifying, alerting and convenience devices for the hearing impaired, has published the second edition of its comprehensive mail order catalog. This informative, fully illustrated catalog offers over 75 different assistive devices and ideas from more than 30 manufacturers. It contains everything from telephone, television and doorbell amplifiers to total

alarm and alerting systems. This unique catalog offers the consumer easy comparison of a variety of products and the convenience of ordering by mail or phone.

Sound Resources, Inc. backs all products offered in the catalog with a 30-day money-back guarantee of satisfaction. For a FREE catalog write: Sound Resources Catalog, 201 East Ogden, Hinsdale, Illinois 60521.

BHI reprints available

WASHINGTON, D.C., September 1, 1985 — A new edition of Better Hearing Institute's *We Overcame Hearing Loss* booklet — adding new personalities who have joined the Institute's public information program — has been made possible by a grant from the Delta Zeta Founders Memorial Foundation.

The new edition will feature the personal success stories of many of the personalities in BHI's award-winning television PSA series, including Art Carney,

Norm Crosby, Phyllis Diller, Nanette Fabray, Lou Ferrigno, Jeff Float, Lorne Greene, Florence Henderson, Bob Hope, Kiel Martin, Frankie Valli, George Wallace and Keenan Wynnne.

A fourth reprinting of Better Hearing Institute's *Tinnitus, or Head Noises* booklet has been made possible by the Hearing Aid Battery Division of Ray-O-Vac Corporation. The pamphlet, which explores the causes of tinnitus and its treatment, is authored by Norman Lee Barr, Jr., M.D., a member of the Institute's advisory board.

A sixth reprinting of Better Hearing Institute's *Nerve Deafness and You* booklet, has been funded by Activair, a division of Duracell Inc. The booklet by Gale Gardner, M.D., has become a classic on sensorineural hearing loss, the most prevalent form of hearing impairment. It shatters common myths and emphasizes that most people with nerve deafness can be helped to hear better with a properly selected and fitted hearing aid.

If you would like a free copy of any of the above booklets write to: Angela Hayden, 5021 B. Backlick Road, Annandale, VA 22003.

POSITION AVAILABLE

Howard Payne University in Brownwood, Texas, announces a vacancy for a clinical audiologist beginning in August.

The minimum requirements include a master's degree in audiology and a CCC-A. Teaching load includes nine hours per semester. The person is also required to maintain an audiological clinic which services a wide range of population. A new clinical audiometer has just been obtained.

Salary is negotiable depending on experience. Summer teaching is also available.

If interested please send vita or contact one of the following people:

Dr. J.W. Cady, Vice President
of Academic Affairs

AAS Convenes In Chicago

The 14th Annual Meeting of the American Auditory Society will be held Monday, September 21, 1987, in Chicago. The site of the meeting is the Inn of Chicago, Ohio Street off Michigan Avenue.

This year the AAS Meeting is being held in conjunction with the annual meeting of the American Academy of Otolaryngology-Head and Neck Surgery (OHNS). The OHNS meetings and exhibits will be located at two hotels: the Hyatt Regency Chicago and the Marriott Chicago. The Inn of Chicago, located in the heart of Chicago's magnificent mile, is just a half block from Michigan Avenue and the Marriott, and one block from the Hyatt. It is one of the designated satellite hotels of the OHNS meeting. AAS members are urged to make their hotel reservations early. The Inn of Chicago, with 350 rooms, is a Best Western

hotel and has recently been extensively remodeled and refurbished. Rates are \$72.00 single, and \$82.00 double.

Planned for this year's meeting is a tutorial session, "An Update on New Developments in Hearing Aid Technology." The format of this session will emphasize reports on what technological innovations manufacturers are about to introduce in the market place.

The Carhart Memorial Lecture will be delivered by Peter Dallos, Ph.D.

David Hill, Chairman of Local Arrangements, has made tentative plans for an evening aboard the Star of Chicago, a luxury cruise boat that affords magnificent views of the Chicago skyline, as well as drinks, and dancing.

Mark your calendars now!

1987 AAS Meeting
Monday, Sept. 21st, 1987
Chicago, Ill.

Aural Rehabilitation Forum

Editor's Note: The following article continues the series of papers which "kicked off" this Forum. In particular, the article prepared by Thayne Smedley, discussing promotion techniques in hearing health care, spirited this issue's segment of the Aural Rehabilitation Forum. Let's keep this relaxed interchange of philosophies going. Send in your contribution!!

Marketing Hearing Healthcare Services to a Minority Population

By Ronald C. Jones & Joann Richardson-Jones

Private practice audiologist **Ronald C. Jones**, PhD heads *The Listening Ear*, a Richmond Virginia "Hearing Health Care Service." He received his PhD in Communication Disorders at the University of Cincinnati. **Joann Richardson-Jones**, MS received her MS degree in Community Health Education at Old Dominion University and serves as community health education consultant for *The Listening Ear*. Their article is based on their presentation at the 1986 annual meeting of the Speech and Hearing Association of Virginia. Correspondence: 10501 Duryea Drive, Richmond, VA 23235.

Most people would agree that the primary responsibility of advertising is to create interest and to attract new prospects to buy the products or services being offered. This is certainly true in the hearing aid industry, where it has been estimated that over 16 million Americans have hearing loss significant enough to warrant the use of a hearing aid.¹ With such a large potential market, it is no wonder that hearing aid advertisements are seen in magazines, newspapers, direct mailings, and, increasingly, on television. Beyond serving their primary purpose, those ads also do much to inform potential users of the problems associated with hearing loss.

What is peculiar about today's hearing aid advertisements, though, is that they appear to be directed to one segment of the potential market: the white middle-class elderly population. Rarely, if ever, does one see an ethnic minority represented in these ads. This omission, intentional or not, promotes the notion that minority populations are not part of the hearing aid market — that they do not experience hearing impairment and, therefore, do not need or use hearing aids. Viewed more critically by a minority hearing-impaired person or his family member, for example, the resulting impression is, "This product isn't for me or mine." Years ago, most companies that sold soap or personal beauty products openly refused to use minorities in their advertisements for fear of offending the majority of their market and scaring off sales. However, considering that today many consumer-goods marketers readily employ minorities in their advertisements to take advantage of a burgeoning market, it would be to the hearing aid industry's advantage to do likewise.

A possible explanation of why the hearing aid industry does not use ethnic minorities in its ads is that minority groups do not appear to represent a significant portion of the hearing aid buying population. Thus when considering advertising budgets, manufacturers and distributors adhere to the adage, "It's better to put your money where it will do the most good." In this case, the white middle-class elderly fit (and can pay) the bill. If that reasoning is to be applied, however, it should be based on logic and on accurate statistical data — not on cas-

ual observations, which from our perspective, appears to be the case.

Minority Market Potential

Although exact figures as to the number of minority persons with hearing problems in the U.S. are difficult to acquire, we can draw estimates from the 1980 U.S. census reports.² Conservatively, we estimate the proportion of the U.S. population with significant communication (hearing and speech) problems at more than 10%. When applied to the 1980 minority population within the U.S. of 40 million, this equates to over 4 million people. Those 4 million, then, would serve as the potential minority market base for the distribution of various communication aids, including hearing aids.

The number of hearing aids actually sold to minority individuals — specifically, to black persons — is also an elusive figure, simply because the industry as a whole does not keep records of such transactions, at least not on the basis of race. A reasonable indicator, however, would be the number of earmolds and/or in-the-ear hearing aids tinted to a dark tone, assuming, of course, that these would be worn by persons with skin tones to match. Most hearing aid and earmold manufacturers do keep records of this type of color modification for the purpose of stocking and reordering dyes and mixtures.

Early in 1986 we conducted a telephone survey of several hearing aid and earmold manufacturers, asking what percentage of their products were tinted. Their replies suggested that tinted earmolds and hearing aids accounted for 1% of the total number of hearing aids sold in the U.S. during calendar-year 1985 was 1,102,887.³ The estimated one percent of that figure translates to a little over 11,000 hearing aids sold, presumably, to individuals of dark complexion.

Minority Market Survey

With those figures in mind, we set out to discover why, with such a relatively large minority market base for hearing aids, there was not a larger percentage of minority purchases of hearing aids? What factors are involved in minority members' decisions to seek or not to

Continued on p. 6

From The Editor

Well, once again I must include an uplifting message to our readers. Believe it or not, developing a creative and entertaining "message" for each issue is becoming more and more difficult.

Rather than burden you in this issue with pleas for articles, etc., I'd like to take this opportunity to thank those who have responded to my previous requests. Although patience has never been a virtue of mine, the support of some new writers and some very special friends has taught the skill of "waiting." I realize that over a year has passed since I began my begging for new and innovative columns, and, with this issue, it has paid off. Some exciting new

segments are included in this copy of *Corti's Organ*. Thank you, Matt, for two GREAT columns. "Name That Lesion" and "Audiology Trivia" should really get our readers thinking (we hope)! We'll keep our fingers crossed that these first editions of the columns will generate more. (Moral to our readers: You too can be creative; send material to Matt! Don't just sit back and let the other guy have all the fun. If you want columns like these to continue, pitch in!)

Thanks also to the recent contributors to the Aural Rehabilitation Forum. After a series of three articles, edited by Ron Schow, we finally received another paper. As can be seen from this issue's column, this segment is exactly what it claims to be — A FORUM. Thank you to those who have allowed the tradition to continue. (Moral to our readers: Let's not let the tradition end here. I'm confident that you have a personal platform hidden somewhere in your career.)

And a final thank you to Susanne Kos, Ross Roeser and Frank Brister. Without their support and encouragement, my impatience would have overwhelmed me. Their confidence kept me going even when my Editor's Mailbox was empty. Thanks for being such good friends.

In closing, let me remind you of other new additions to *Corti's* that are hopefully in its future. We need to hear from you for the "What Bugs You" column and for "Letters to the Editor." Also, don't forget that one of our next issues will be dedicated to a nostalgic look at "Ten Years of *Corti's Organ*." Send in your old pictures, old commentaries, etc. We need your ARCHIVES!! AND — one last reminder — Matt needs trivia and lesions, and the AR Forum needs your views.

— Virginia Berry

Reagan Declares May as Better Hearing And Speech Month

All Americans can be encouraged by advances in the help available for the more than 24 million Americans who have hearing, speech and language impairments. These problems, of course, can cause great difficulties for those who have them, so it is wonderful to know that improvements in medical and surgical treatment, hearing and speech rehabilitation and hearing aids are helping many people significantly.

Better Hearing and Speech Month is an excellent time for all of us to take advantage of educational programs to increase our awareness about hearing and speech problems, to improve our understanding of our fellow citizens who suffer from them and to learn about current research. We must realize, for instance, that because the percentage of older people in our population is rising and will continue to do so, the incidence of hearing impairments is growing. That is because more than one in three over age 75, have a hearing disorder.

Help and hope will continue to reach Americans with impairments in hearing and speech as long as all of our citizens take part in efforts like those of Better Hearing and Speech Month. I'm happy to urge every American to participate in this observance — in every way possible. God bless you.

Ronald Reagan

The President's Corner

Years ago while I was a resident I noticed that parents seemed to suspect hearing loss when their babies were 9 to 10 months of age. In nearly every instance the pediatrician made a delayed diagnosis or referral at about 20 months (based on 100 children ultimately found to have profound hearing loss).¹ Recently in Ann Landers' column a letter, written by an angry mother, recounted the failure of her pediatrician to make a referral. She finally got a consultation on her own, which confirmed the presence of a severe hearing loss.

I realize as I write this diatribe, that I am addressing the "Christians" not the "atheists". What I am attempting to do is make evangelists of the Christians and propose a study of this phenomenon, using investigators from several institutions. My concept is that we should pit the parents against the pediatricians to see who identifies the deaf child earlier. It should be acknowledged that each group has advantages: the parents are with their infants every day, and the pediatricians only see them at intervals. However, the pediatricians have had access to numerous journal articles, including an entire issue of *Pediatric Annals*, which have dealt with childhood and infantile deafness, the importance of early identification, and habilitation. Where does all this educational material go? Does it end up in a corner of

the brain where useless information is put through the cerebral shredder?

My plan is this: experimental and control groups for both parents and pediatricians with double blinding of their scores. Control group will include parents whose children have normal hearing, but who are thought to be neurotic parents because their pediatrician told them. Pediatricians will be randomly assigned to control or hearing-impaired groups without knowing which is which. The children and their parents will see their own pediatrician. All parents will have a coded postcard to mail to their principal investigator which will indicate whether the pediatrician either sought consultation or made the diagnosis himself, based on subsequent consultation elsewhere. I blew it. The individual pediatrician will not know he is in the study or that there is even a study being done. This will leave him free to conduct himself as he always does.

No doubt I will be assassinated shortly after this article is printed, but if good comes of it will be worth it.

— LaVonne Bergstrom

Audiology Trivia

Edited By
Matthew W. F. Smith

A remarkable phenomenon of the 1980's has been the tremendous interest in trivia of all types. It became apparent to us that the field of Audiology, which has its roots in multiple disciplines, is a virtual cornucopia of trivial material. We are pleased to present our first harvest of Audiology Trivia, which was compiled by the editor. We invite your participation in this new American tradition. Please send your interesting Audiology Trivia along with a reference source to:

AUDIOLOGY TRIVIA
605 Burma Drive, NE
Albuquerque, NM 87123

We will acknowledge your contribution in this column. Now let's play **AUDIOLOGY TRIVIA:**

ERRATA

Susan Jerger's name was erroneously substituted for Deborah Hayes' name on the list of Executive Committee members in the Winter, 1987 issue of *Corti's Organ*. Susan Jerger did, however, take over Deborah's duties on the Editorial Board of *Ear and Hearing*. The editors sincerely apologize for this mistake.

TRIVIA QUESTIONS:

- Q1:** What now famous student of Zwislack spent evenings and weekends in search of still warm cadavers for middle ear physiology studies?
- Q2:** Who first described the cochlea as the primary organ of hearing?
- Q3:** Who was the author of Weber's Law?
- Q4:** What was Raymond Carhart's favorite mode of transportation?
- Q5:** Which audiometer was used to evaluate hearing of the Mercury astronauts?
- Q6:** What psychophysical method is synonymous with method of reproduction?
- Q7:** What unit is used to express noisiness?
- Q8:** What psychophysical method is synonymous with method of serial exploration?
- Q9:** How thick is Reisner's membrane?
- Q10:** Which internationally famous audiologist has a daughter who is a television motion picture critic?
- Q11:** Which audiologist's business card bore the cartoon character Noisius Racket (The Noise Bug)?

Trivia Answers — see page

1986 AAS MEETING AVAILABLE ON VIDEOTAPE

The 1986 meeting of the American Auditory Society is now available on videotape.

The videotape is approximately 6 hours in duration. It includes the Carhart Memorial Lecture by Joseph E. Hawkins entitled

"TRACES OF AGE IN THE EAR AND THE EYE"

The videotape is available in VHS format only. To order, send the specified amount after checking one of the below:

- _____ I am sending a T-120 blank videotape. Please duplicate the 1986 convention tapes and return it to me. Cost = \$25.00
- _____ I am not sending a blank videotape. Please send me a copy of the convention tapes. Cost = \$35.00

Make check payable to the American Auditory Society.

Send order to: Michael F. Seidemann, Ph.D.
Jo Achim Eye, Ear, Nose and Throat Hospital
145 Elk Place
New Orleans, LA 70112

The videotape should be mailed to:

Please allow 4-6 weeks for delivery.

Mr. James Keyes, President
Audiotone, Inc.

An Important Message from Audiotone

Dedicated to Making
**OUR COMPETITIVE EDGE,
YOUR COMPETITIVE EDGE.**

A major Audiotone strength has always been its **PEOPLE** . . . from your factory representative to our engineers . . . from our production department to the shipping room . . . all throughout our organization. Audiotone is dedicated to continue this long tradition of having caring, understanding, and experienced people whose primary objective is to serve you.

Additionally, Audiotone is proud of its history of commitment to **PRODUCTS** and **PROGRAMS** — all for you, the hearing aid dispenser.

Now, you will experience even more . . . A NEW AND IMPROVED MARKETING PROGRAM to ensure your Competitive Edge. Be a part of this Program as it unfolds. And, it begins with **PEOPLE**. People dedicated to a winning attitude, and sharing our success with you.

This winning attitude . . . these experienced professionals . . . and our full line of quality, dependable **products** and **programs**, all lead up to **your** continuing advantage.

OUR COMPETITIVE EDGE

MEET THE EXECUTIVE

AUDIOLOGISTS

Frank E. Musiek, Ph.D., Director of Audiology and Professor of Otolaryngology and Neurology, Dartmouth-Hitchcock Medical Center, Hanover, NH. Ph.D., Case Western Reserve University, 1975. M.A., Kent State University, 1971. B.S., Edinboro University, 1969.

The American Auditory Society has enjoyed considerable membership growth during the past decade. This growth has as its basis several important factors that are the essence of this society. The membership is diverse and represents the major facets of the hearing health care system. The excellent leadership of the AAS has fostered communication both within the membership as well as with the associated medical societies. It has an ever improving journal which has gained recognition for its high quality and relevance to the hearing professional. All of the aforementioned have become increasingly important at a time when the profession is facing new and ever changing challenges. The issues of professional independence and respect, private practice, integration of technological advances, and appropriate training of future professionals and the opportunity for broad based and updated continuing education require discussion, direction and resolution at the national level.

I believe the AAS can play a major role in the mediation of these issues. However, this may necessitate more active political involvement on the part of AAS to represent its constituency and their concerns, both at a state and national level. In addition, continued dialogue between the associated health care professions is of utmost importance. It is through these activities that AAS can continue to meet the goals of the society and the concerns of the hearing professional.

Deborah Hayes, Ph.D., Director, Audiology and Speech Pathology, The Children's Hospital, Denver. Ph.D., Baylor College of Medicine, 1979. M.A., 1973. B.S., Northwestern University, 1971.

My affiliation with the American Auditory Society has been a very rewarding professional experience. In the past four years, the Society has grown in membership, stature and contribution to the professional community. The unique interdisciplinary nature of the Society provides a forum for exchange of ideas, debate of controversy and increase in knowledge for all of its members. Our journal, *Ear and Hearing*, is now considered one of the finest in audiology; our annual meeting continues to grow in attendance and visibility. I have been proud of my association with the Society, and would enjoy the opportunity to continue this association on the Executive Committee. I would like to see the Society continue its steady growth, attracting new membership from all professions dedicated to prevention, identification and habilitation of hearing loss. I would encourage the continued excellence of our journals and meetings, and strive to make these activities important, valuable and attractive to our members. Finally, I would encourage the society to develop a presence within the national and international arena which would recognize the unique and important role of the American Auditory Society to the professional community.

John T. Jacobson, Ph.D., Director of Audiology, Geisinger Medical Center, Danville, PA. Ph.D., Special Education, San Francisco State College. M.S., Audiology, Oregon College of Education. Ph.D., University of Utah.

To date, the AAS has provided an open forum for the hearing health community. The common denominator has been, simply, a sincere interest in audition. Through the publication format and convention meetings, AAS offers one of the few vehicles available for interdisciplinary interaction in communicative disorders and diseases. This primary function of the organization must be strongly advocated and continually supported.

To many, however, AAS is more than just an association with a collegiate atmosphere. To those, it personifies the aspirations and voice of the future. AAS is the only organizational body that has the capability to truly represent its membership and the capacity to act on their behalf. The Society has reached a point in its development that it must re-evaluate its goals and directions. A key question that cannot be dismissed is whether AAS should remain a relatively neutral, apolitical body, or, as an organization, begin to address controversial issues that currently face the profession and possibly, its very thread of existence. I envision the AAS expanding its role with other professional groups, advocating standards where none exist, and increasing its profile at the national level.

Michael F. Seidemann, Ph.D., Director of hearing and Speech, Eye, Ear, Nose and Throat Hospital. Ph.D., Audiology, Florida State University, 1973. M.S., Audiology, Old Dominion University, 1969. B.S., Psychology, Old Dominion University, 1968.

During the course of its brief existence, American Auditory Society has been able to achieve a position of esteem and leadership in the hearing health care community. It has a distinction of being one of the very few truly interdisciplinary organizations providing forums for the exchange of information between audiologists, otolaryngologists, hearing specialists and hearing instrument manufacturers. Our journal now seems to enjoy the position of being the outstanding publication in audiology. The annual convention has consistently been excellent.

Since we're so wonderful, where do we go from here? There are two areas in which I feel we should focus our attention. While our society is interdisciplinary, our membership is very small in representation of all disciplines except audiology. I therefore feel that we should more actively recruit new members from those other professions. Such input should serve to broaden our perspectives. The second area of focus which I feel we must come to grips is the scheduling of our annual convention. It has become increasingly difficult for us to cover the necessary exchange of information in the one-day format of our annual convention. We should therefore study and determine whether or not a change in format is warranted at this time.

OTOLARYNGOLOGISTS

B. Hill Britton, M.D., Associate Professor, Section of Otolaryngology, The Bowman Gray School of Medicine, Winston-Salem, NC. Otolaryngology Fellowship, The Otolaryngology Medical Group, 1966. Otolaryngology, residency, USC, 1963-67. M.D., University of Oklahoma, 1960. B.A., University of Oklahoma, 1956.

I am deeply honored by the Nominating Committee's asking me to be a candidate for

the Executive Committee of the American Auditory Society. It is my opinion that the purpose of the American Auditory Society is well stated in Article II of the Society bylaws. The stated aims are to increase knowledge and understanding of the auditory process, to promote conservation of hearing and to foster habilitation and rehabilitation of persons with hearing impairment. It is also stated that the Society shall coordinate the exchange and dissemination of information concerning these aims. Regarding future directions of the Society, it is my feeling there is no status quo. Either a society continues to advance or it becomes stagnant and ineffective. In the current climate of cost containment pressures, all hearing health care professionals must continue to be the advocate of patients with hearing disorder. All effort must be made to work effectively as a team for the patient's benefit. Any problem encountered in providing optimal care for our patients by any member of this team, should become a concern of the entire membership. A concerted effort by all hearing health care providers should address pertinent problems and see solutions. This Society should function as a forum, addressing these issues and problems, and seeking the advice and wisdom of the members. Ongoing communications between society members, as well as with other allied health fields, should continue to be stressed. The Society has a unique opportunity in the future to further contribute to the well-being of all of our patients.

Serge A. Martinez, M.D., Professor of Surgery and Director of the Division of Otolaryngology, School of Medicine, University of Louisville, Louisville, KY. M.D., University of Miami, 1969.

The American Auditory Society is an organization on the leading edge of advances in ear and hearing. A review of the organizational leadership and membership discloses individuals interested in all aspects of audition, basic

research and communicative disorders. The Society meetings have become known for the quality presentations and discussions, and the tendency to foster production of new ideas. Awareness of the Society goals by students in audiology training programs, as well as by residents in Otolaryngology, increases yearly.

Many of the organizations in medicine and health sciences tend to evolve into social organizations which serve only a handful of members who rotate organizational leadership among themselves. Such a group takes on a predictable aura which tends to discourage new thought or energetic membership. The American Auditory Society has not done this, and, if it continues on its present progressive course, it can be the vehicle for the presentation and promotion of major advances in hearing. The development of new and sophisticated devices to assist hearing has brought about great public awareness and appreciation of hearing loss. A quality organization devoted to greater understanding and newer treatments of this affliction will be strongly supported in various ways, not the least of which are political and financial.

I think all of us who are members of the Society are so because of the association we have had with other members of the Society, and because of an appreciation of the ideal and interests of Society as a whole. It is evident that the advances in the understanding and rehabilitation of audiovestibular disorders have been made by individuals who are among the Society's membership.

COMMITTEE CANDIDATES

—HEARING SCIENTISTS—

After receiving a ballot by mail, each member should select two otolaryngologists, one hearing scientist, and two industry representatives for Executive Committee membership beginning in 1988.

Josef M. Miller, Ph.D., Professor and Director, Kresge Hearing Research Institute, Ann Arbor, MI. Department of Otolaryngology, University of Michigan. Ph.D., University of Wash-

ington, 1965. B.A., University of California, Berkeley, 1961.

I believe that our field will only grow by the collaborative and coordinated efforts of its various constituents. Whether it be by our efforts to recruit support for fundamental research, by our efforts to prevent occupational hearing loss, or by our clinical efforts to detect and treat hearing disorders, we must increase the effectiveness of collaborations among the professionals of our field. The American Auditory Society, more than any other group, includes among its membership individuals who represent perhaps the most varied constituency of any society in our field. It encourages communication among audiologists, basic researchers, industrialists, government administrators, and physicians. Its organization, development and interests reflect less the special interests of a particular group than any other society. This is a strength. This we should exploit for the further growth and development of our field. Through special symposia at our meetings, special invitees and increased liaison with the officers and councils of our other professional societies, the American Auditory Society may be in a special position to foster the development of our field.

Mead C. Killion, Ph.D., President, Ety-motic Research, Elk Grove Village, IL, Adjunct Professor of Audiology, Northwestern University. Ph.D., Audiology, Northwestern University, 1979. M.S., Mathematics, Illinois Institute of Technology, 1970. A.B., Mathematics, Wabash College, 1961.

The American Auditory Society continues to serve a vital function as an antidote to the "turf" protecting tendency of professional organizations in the field of hearing assessment and hearing aid dispensing. Its combination of personal informality and highest-standard publication activity in its journal *Ear and Hearing* have made it a vital force in our field.

—INDUSTRY REPRESENTATIVES—

J. Gail Neely, M.D., F.A.C.S., Professor and Head, Department of Otorhinolaryngology, College of Medicine, University of Oklahoma. Otolaryngology Fellowship, Otolaryngologic Medical Group, 1972-73. Otolaryngology residency, Baylor College of Medicine, 1969-72. M.D., University of Oklahoma, 1965. B.S., Biology and Chemistry, Central State University, Edmond, OK.

The American Auditory Society is a unique organization composed of audiologists, auditory system scientists and otolaryngologists who personally and collectively demonstrate a focus to patient care and academic productivity directed toward the hearing impaired patient. This organization exemplifies my particular philosophical bias of the imperative of teamwork between professionals devoted to the care of hearing impaired patients. I would see the purpose and the future direction of the society to be one of example and continued educational dissemination of this philosophy toward the objective of improved patient care and scientific advancement.

Toni Gittles, M.A., Vice President of Professional Services, Electone, Inc., Winter Park, FL. M.A., Audiology, Northwestern University, 1973. B.A., Education, University of Florida, 1971.

The American Auditory Society is unique in its appreciation, recognition and encouragement of membership from all sectors comprising the hearing health care profession. This includes audiologists, hearing aid dispensers, physicians and representatives from industry. I am fortunate to have been involved in some manner of education and/or experience in all these areas. It is quite clear that all individuals, with their differing backgrounds, have their own perspective on the various issues that affect our profession. AAS has set the example that each perspective is important, and it provides the vehicle for sharing and disseminating all viewpoints. The openness and willingness to communicate, absolutely essential at this time of so much transition, is a noteworthy accomplishment of the organization and should be beneficial to the recruitment of new members.

The precedent already set for education through the yearly meetings, *Corti's Organ* and *Ear and Hearing* represents a high standard of excellence which should be supported.

James R. Curran, M.S., Research Audiologist and Professional Accounts Manager, Starkey Laboratories, Minneapolis. M.S., Communicative Disorders, University of Wisconsin, 1962. B.S., Speech Pathology, University of Minnesota, 1961.

I have been pleased to observe the extraordinary success of our journal, *Ear and Hearing*, as the years have passed. It is in the top rank of professional journals concerned with hearing and hearing impairment. I feel that no stone should be left unturned in continuing to maintain and improve its editorial excellence.

I have been a member of the Society since the very beginning, and it has been gratifying, in addition, to see one of the original aims of the organization fulfilled: to create an environment of mutual understanding and fellowship between members of the medical, audiological and hearing health industry communities. This can be a difficult task at times, because individuals and groups may seek to enlist the Society as an ally on one side or another of controversial issues. We should stand aloof from such attempts, if at all possible, and continue to act in an even-handed manner towards all, always remembering that this Society was founded primarily to increase our understanding of the auditory process, to promote hearing conservation, and to foster hearing habilitation and rehabilitation. This charter leaves precious little room for internecine bickering and political maneuvering.

William F. Carver, Ph.D., President, AUDITEC of St. Louis. Ph.D., Audiology, USC, 1960. M.A., Speech Pathology and Audiology, 1955. B.A., Psychology, USC, 1951.

Through dedicated leadership, the American Auditory Society has not only grown in numbers, but more importantly, in scientific professional stature. The principle of encouraging membership of anyone whose interest and professional experience lies in the ear and hearing is one of the hallmarks of this organization and has been a key to its success. We now have a mature journal which publishes learned articles of original research. We have well-attended, interesting and provocative meetings. We have an organization which exists without the politics which pervade and weaken the aims of many professional organizations. (And we know how to have fun as well!)

The goals of the AAS should be: 1) to persist in our growth towards becoming a major influence in the field of audition, 2) to encourage the extension of the body of knowledge of auditory processes, 3) to provide an unbiased forum for discussion and learning, and, 4) to continue to disseminate information to the membership and to society as well. It may seem trite, but through these philosophies and goals, the ultimate beneficiaries will be the hearing handicapped. I can think of no loftier goal for the Executive Committee than to continue supporting the philosophies of this organization, to augment the promulgation of knowledge, and to carry on with the development of new members who are as interested as we are in these goals.

Aural Rehabilitation Forum

Continued from p. 1

seek hearing health care, and was there a minority market for hearing healthcare services in our area?

In an effort to answer those questions, we conducted a market survey during a series of hearing-health screenings held at community centers and churches throughout the central-city area of Richmond, Virginia.

The results reported here reflect the responses to parts of that survey of 230 black adult and/or senior citizens, some of whom, we found, were hearing impaired and were familiar with the problems associated with hearing loss. (None of the respondents, however, wore hearing aids at the time they were surveyed.) The respondents ranged in age from 24 to 96 years, with an average age of 67.3. Sixty-two percent were women, 38% men. Of the 230 respondents, 75, or 33%, failed the hearing screening.

For purposes of comparison, the responses to several of our survey questions are presented with responses from the general population to several other market surveys reported in the literature.

Why Not Get a Hearing Aid?

We first asked respondents to review a list of potential reasons for not obtaining a hearing aid and to cite the reason(s) most applicable to them. As shown in Table 1, while the vast majority of general-population survey respondents cited the fact that a hearing aid "probably wouldn't help" them, an even larger majority of the minority population we surveyed cited cost as the principal deterrent to a hearing aid purchase.

Table 1. Comparison of percentage of minority- and general-population respondents citing various reasons why one might not obtain a hearing aid. (General-population responses taken from data reported by Skafte in 1985.)

Reasons One Might Not Obtain Aid	Minority Respondents	General Population
Probably wouldn't help	6%	61%
Don't want others/know	4%	8%
Would be inconvenient	1%	6%
Costs too much	82%	3%
Looks unattractive	2%	3%
Only for old people	5%	16%

Hearing Health Low Priority

We then asked certain respondents, "During the year following your suspicion of having a hearing problem, did you have a hearing examination?" As seen in Table 2, slightly more than half of those in the general population answered affirmatively,³ compared to only 4% of minority respondents to our survey (2 out of 45 respondents, in the case of this question).

In a related question, we asked all respondents to offer a forced-choice "yes" or "no" opinion of several reasons why members of the minority population might not seek help for their hearing problems. The reasons drawing the greatest percentages of "yes" answers were: (1) unavailability of services, 88%; (2) cost, 86%; (3) low health priority, 73%; and (4) lack of understanding, 27%.

That hearing health is a relatively low healthcare priority among our respondents was especially — but not surprisingly — evi-

Table 2. Minority- and general-population responses to the question, "During the year following your suspicion of having a hearing problem, did you have a hearing examination?" (General-population responses taken from data reported by Broenen in 1983.)

Hearing Examination	Minority Respondents	General Population
YES	4%	56%
NO	96%	44%

dent in their answers to another set of questions. Asked to rate the urgency of and need for attention to two sets of health problems, 100% of the respondents agreed that heart conditions, stroke and high blood pressure, arthritis, and broken bones and sore joints are more urgent and require more attention than hearing loss. Asked then to rank the importance of the latter three conditions, 86% of the respondents cited vision loss as the most serious; 11% cited hearing loss; and 3%, dental problems.

Cost Perceptions

Already having cited cost as a major deterrent to hearing aid use, respondents provided further detail on their perceptions of hearing aid costs in their answers to two other questions.

Asked, "From what you have heard, what do modern hearing aids cost?" 51% of the respondents answered, "Between \$500 and \$750." Another 46% said \$250 to \$500. Only 3% replied \$750 to \$1000, while no respondent believed hearing aids cost between \$100 and \$250.

We then asked, "If you feel the cost of hearing aids is too high, what would you be willing to pay for one?" In this case, the vast majority — 74% — said they would pay \$250. Of the remainder, 18% indicated that they would pay \$500 for an aid, while none said they would pay \$1000. Similarly, not one respondent replied, "I don't feel their cost is too high."

Finally, the survey explored the hearing health or medical professionals that minority consumers were most likely to consult about a hearing problem.

Asked, "If a hearing problem develops, who would you go to see about it?" a total of 89% reported that they would visit a family doctor or an ear doctor — a percentage comparable to that of the general population who said they would do likewise.¹ Hearing aid dispensing audiologist and "hearing aid dealers" did not fare nearly as well, cited respectively by 9% and 2% of minority respondents as the first-review professional. Table 3 details minority and general-population responses to this question.

Table 3. Minority- and general-population responses to the question, "If a hearing problem develops, who would you go to see about it?" (General-population responses taken from data reported by Hearing Industries Association in 1986.)

Hearing of Medical Professional	Minority Respondents	General Population*
Hearing Aid Dispensing Audiologist	9%	32%
Hearing Aid Dealer	2%	10%
Ear Doctor	45%	42%
Family Doctor	44%	42%

*HIA question allowed respondents to indicate more than one professional.

Discussion

The results of our survey identify several factors that might explain why the U.S. minority hearing-impaired population fails to avail itself of the benefits of hearing aids. One is a general lack of awareness on the part of the minority consumer of the potential benefits of using hearing aids. This might be due in part to the poor promotional image projected in advertisements by the hearing aid manufacturers and dispensers, regarding minority use of their products and services. The paucity of minority-owned hearing aid dealerships or the lack of exposure of minority hearing health professionals to the community at large could also be contributing factors.

Another factor that affects minority purchases of hearing aids is price. The relatively high cost of hearing aids — e.g., \$450 to \$600

A Sail of Two Cities

The Southern Audiological Society's 15th annual convention cruise aboard the "Mardi Gras" originally sailing from Ft. Lauderdale on Thursday, September 10 has been changed.

Departure will now be from Miami for Nassau on Friday, September 11 aboard the sister ship "Carnivale," returning on Monday, September 14, 1987.

These changes have resulted in some special benefits. All SAS group passenger cabins will be upgraded a minimum of two categories. Each passenger will now receive a \$15 bar credit and there will be a complimentary bottle of champagne in each cabin!

For more information please contact:

Meeting on Outdoor Sound Propagation

A one-day meeting of the Institute of Acoustics on outdoor sound propagation will be held at The Open University, Milton Keynes, on September 5, 1987. Many aspects of the topic will be covered, and the focus will be on recent research findings. Of particular interest will be a discussion of work on the influence of ground and meteorological factors and assimilation of this knowledge into practical prediction schemes.

For more information, contact the meeting organizer Dr. Keith Attenborough, FI, Faculty of Technology, The Open University, Milton Keynes, MK7 6AA, UK.

19th International Congress Scheduled

The International Society of Audiology will hold its 19th INTERNATIONAL CONGRESS OF AUDIOLOGY in Jerusalem, Israel, June 5-9, 1988. Topics of the Round Tables are: Hearing Dysfunction Associated with Systemic Diseases, Methods for Evaluation of Benefits of Hearing Aids, and Auditory Deprivation from Middle Ear Disease (in children). Free paper sessions on a variety of topics in audiology will be held throughout the four-day congress. For further information please contact: 19th International Congress of Audiology, P.O. Box 50006, Tel-Aviv 61500, Israel.

Name That Lesion

A Forum for Case Studies
Edited by
Matthew W. F. Smith

As practicing audiologists, we encounter many interesting and unusual cases regularly. You know, that one really interesting case out of a hundred mundane encounters which piques your interest and makes the routine stuff endurable. While most of these unusual cases would not be considered deathless prose suitable for juried journals, they usually teach us something and may be helpful to our colleagues. As practicing clinicians, we have hundreds of thousands of wo/man-hours of clinical experience among us. With that in mind, the editors of *Corti's Organ* have created this forum for case presentations. This is **YOUR** clinical forum. Without your input it will perish. Let's hear from you today. Please send your clinical case experiences to:

NAME THAT LESION
605 BURMA DRIVE, NE
ALBUQUERQUE, NM 87123

The first case is presented here by the editor from his private experience. Future case presentations will be from your clinical experiences.

CASE NAME:

The Case of the Dizzy Nose

PRESENTERS(S):

Matthew W. F. Smith, M.Sc., CCC-A

Karl W. Hattler, Ph.D., CCC-A

ADDRESS:

Hearing Evaluation Center

612 Encino Place, NE

Albuquerque, NM 87102

This is the story of our patient, R.A., a 42 year old male who was an amateur basketball player with a deviated nasal septum.

R.A. was being seen by his otolaryngologist for a routine history and physical on the evening before his scheduled nasal surgery. He reported a history of severe nasal meningitis some twenty years previously with apparently complete recovery except for unusual ocular movement which his doctors had reportedly attributed to the meningitis.

R.A. denied having trouble hearing people but did experience occasional difficulty using the phone with his left ear. When questioned about dizziness or tinnitus he denied having tinnitus, but thought he had experienced a little dizziness now and then when turning rapidly to make a hook shot while playing basketball.

His otolaryngologist referred him to us for a precautionary hearing examination. The first thing we noticed about this patient was his unusual ocular motor activity. So we spent a few minutes observing his eyes. There was an asymmetric eyeblink with the left eyelid trailing the right. Also, the left eye blink seemed to be weaker than the right. There was a right-beating gaze nystagmus. There was also a definite internuclear ophthalmoplegia, a time lag between the two eyes on smooth pursuit tracking.

In the sound room, he did notice a very mild ringing tinnitus on the left side. On closer

questioning, he recalled episodes of light-headedness and described some numbness around the left ear and ear canal.

Pure tone audiometry (figure 1) revealed essentially normal hearing sensitivity on both sides with no significant asymmetry present, although the left ear thresholds were slightly elevated. Speech audiometric thresholds were asymmetric by just 10 dB, worse on the left. There was a significant difference in word intelligibility scores obtained at a 40 dB sensation level, with the left ear score some 56 percent worse than the right.

Special tests of auditory function yielded mixed results. There was no threshold tone decay seen using the modified Carhart method. The Simultaneous Binaural Median Plane Localization test (SBMPL) showed him to be unable to fuse a binaural signal into a mid-plane image.

Electro-acoustic impedance audiometry (figure 2A and 2B) yielded essentially normal looking tympanograms with a mild negative pressure seen on both sides (-50mm on the right and -140mm on the left).

Acoustic reflexes (figure 2C) were present on both sides at slightly elevated levels with contralateral stimulation. Reflexes were seen at normal levels on both sides with ipsilateral stimulation. Reflex decay (figure 3) was normal measured on the right with stimulation to the left (now suspect) ear. Reflex decay results were very abnormal measured on the left with stimulation to the right (by now considered the normal) ear. The reflex seemed to decay completely then restart with a two second periodicity.

Because of the symptoms and audiological data, an Auditory Brainstem Response test was performed. All five waves were seen on the right side at 90 dB HL (100 dB PeSPL) with normal absolute and interpeak latencies for waves I through IV at a stimulus rate of 11.1 Hz. Wave V was late at a stimulus rate of 11.1 Hz, and could not be seen when the stimulus rate was increased to 44.4 Hz. (See figure 4A)

The left ABR (figure 4B) was grossly abnormal with only waves I and V discernable at 90 dB HL (100 dB PeSPL) at a stimulus rate of 11.1 Hz. The absolute latency of Wave V was abnormally long as was the I-V interpeak latency. A comparison of the I-V latencies from left to right showed a difference of only 0.11 milliseconds.

Auditory Brainstem Responses on both sides were poorly replicable.

This ABR was interpreted as indicating a diffuse brainstem lesion affecting both sides of the brainstem.

We recommended to the otolaryngologist that R.A. be referred for neurological evaluation as well as diagnostic imaging. The nasal surgery was postponed and the patient received an immediate CT Scan. NOTE: this case occurred before the availability of Magnetic Resonance Imaging.

CAN YOU NAME THAT LESION?

For result, interpretation, and diagnosis, see page 31.

Aural Rehabilitation Forum

Continued from p. 6

—is a deterrent to those minority individuals who may need hearing help, but who are also economically depressed or living on fixed incomes. Also evident is the fact that hearing health is a lower-priority item than other healthcare concerns.

An area not addressed directly in our market survey was attitude toward communication problems. Implied or alluded to by many of the respondents during their hearing screenings was the belief that hearing loss and hearing problems are simply an expected by-product of old age. This point requires further observation and examination, particularly if more effective approaches at marketing to minority populations are to occur. In any event, the provision of hearing healthcare services that accommodate the expressed needs of this population — identified by way of surveys or other methods — appears to be a step in the right direction.

Marketing Strategies

As a result of this market survey, our firm has made aggressive efforts to better address the communication needs of this minority population. We have developed specific marketing strategies that are showing positive results. The following is an outline of these strategies, shared in hope that other hearing health professionals can glean something that would be of benefit to the minority populations they may be willing to serve.

Tailor Goals to the Market

The first element of our overall marketing strategy was to establish goals that reflect the attitudes and needs of the target population.

The results of our survey suggested that hearing loss, although important, is not a high-priority concern among the minority members of this particular community. They have other, relatively more serious health concerns that must be addressed first.

Our objective, then, is to provide, in addition

to hearing healthcare information, information on general healthcare concerns (e.g., hypertension, low-salt diets, stress management, preventive healthcare) that will assist our customers in maintaining their general health. One of our new goals is to serve as a referral source within the minority community for healthcare services in general, with hearing health care our primary service offering.

Establish a Relevant Image

The second major aspect of our strategy was to establish a market "image" to which the members of the community can relate. The elements of that image include:

1. The products/services being offered;
2. The prices attached to products and services;
3. The location of the business; and
4. The promotional or advertising strategies used.

Execution

In implementing that overall strategy, we have incorporated in our practice the following approaches to marketing hearing services specifically to minority populations:

Product

Our products and services are displayed in a way that enables the target population to relate to their use. Any photos or illustrations that we use depict minority persons either wearing hearing aids or being serviced by a minority professional. This approach has increased the number of inquiries about and requests for our services.

Price Structure

In establishing a price structure for our products and services, we considered two contrasting pricing philosophies:

The price/quality or cost/benefit approach. This approach is thought to communicate a high level of professionalism and product quality but has proven to be a deterrent to the lower- and fixed-income individuals with whom we

regularly do business, many of whom do not readily recognize the implied price/quality relationship, but in fact have tended to view the typical retail price of hearing aids to be exorbitant.

The bargain pricing approach. Many believe this to be the weaker of the two pricing philosophies, because it tends to communicate to the consumer a less expensive — and thus inferior — product or service. However, for cost-conscious consumers like ours, bargain pricing has a definite appeal. Since adopting this approach, we have been able to maintain the quality of our products and services, largely, we believe, through a conscientious and personalized approach to our service delivery.

Location

In launching our business, we considered two general location options: either a business-district location or a home-based operation.

We recognized that a business-district location would be convenient only to those clients who resided in the vicinity of the office. Transportation to such a central location would be a major problem for many of our potential customers. We also realized, however, the need for a central location for stocking our inventory, as well as for a centrally located service/repair center. Although the idea was "old fashioned," we decided to use a home-based operation, in which we could make home visits for sales and service delivery. This arrangement is convenient for the consumer and it allows us to provide our service in the consumer's principal communication setting: his or her home. Our stock and servicing are provided in a separate office maintained for those purposes.

Promotion

We use advertising to generate attention and to provide information about products and services. Given the broad market base of an urban setting like Richmond, Virginia, there are numerous avenues available to advertise and pro-

mote hearing healthcare products and services. We have found that advertisements that go directly to the consumer — and in the case of this population, radio ads, direct mailings, and personal promotions — tend to be the most effective. One approach that we are finding productive is to provide periodic hearing hearing screenings at community centers and churches throughout the community, an activity that generates customers and at the same time provides the community with a needed service.

Conclusion

The decision to establish a hearing healthcare business within a minority community was fraught with anxiety — primarily because the industry, by and large, does not address the particular needs of the minority dispenser serving this segment of the population. This remains particularly true with regard to manufacturing promotional materials, which are devoid of identifiable ethnic representations. As a result, we undertook a different approach, which incorporated new and better advertisements and promotions. Our practice now has a foothold within the ethnic minority community of a major U.S. city, and our growing success is in part to marketing strategies tailored to the population we serve.

ARO Celebrates Tenth Anniversary at its Midwinter Meeting

The Association for Research in Otolaryngology (ARO) held its tenth annual Midwinter Meeting in Clearwater Beach, Florida, from February 1 to 5, 1987. Over 575 scientists attended the meeting at which 330 papers and posters were presented on a wide range of scientific topics. The science meeting was highlighted by a special symposium on Noise-Induced Hearing Loss and by workshops on New Techniques for Otolaryngology, Otosclerosis, and Biological Models in Otolaryngology Research. These activities were organized by Dr. Donald W. Nielsen, President of the ARO. The meeting was partially supported by grants from the National Institute of Neurological and Communication Disease and Stroke (NINCDS), the U.S. Army, and the Committee on Hearing, Bioacoustics, and Biomechanics (CHABA) of the National Research Council.

Dr. Nielsen presided over the meeting which included a celebration of the tenth anniversary of the ARO Midwinter Meeting. Drs. David Lim, Harold Schuknecht and Jurgen Tonndorf presented a brief history of the ARO at a banquet attended by 260. The ARO presented its annual Award of Merit to Dr. Jerzy Rose of the University of Wisconsin for his many valuable contributions to auditory physiology and anatomy. The award was presented at a banquet held to honor Dr. Rose and to celebrate the tenth anniversary of the ARO Midwinter Meeting. Dr. Joseph Zwislowski, Dr. John Brugge and Dr. Joe Hind reviewed the scientific and personal history of Dr. Rose's brilliant career. A certificate and a gold tie clasp modeled after the inner ear were presented to Dr. Hanna Sobkowitz who accepted the award for her husband, Dr. Rose. The Award of Merit recognized

Dr. Rose's many contributions to the study of the anatomy and physiology of the auditory system. Dr. Rose has made many valuable contributions to our understanding of the structure and function of many parts of the brain, especially those areas that serve hearing. He introduced many new techniques, especially the digital computer, for the physiological study of hearing. His many discoveries form the basis for some of the known fundamental facts and theories of auditory processing. Although retired from full time teaching and research, Dr. Rose continues to work with his wife on research involving the development of the auditory system.

The association voted in 95 new members, bringing the membership to almost 900 members. A slate of new officers was also approved

by the membership: Dr. George Gates, President; Dr. William Yost, President Elect; Dr. Allen Ryan, Secretary/Treasurer; Dr. David Lim, Editor/Historian; and Dr. Charles Parkins, Council Member. They join Drs. Donald Nielsen, Ilsa Schwartz and William Clark on the ARO Council. The 1988 ARO Midwinter Meeting will be held at the Surfside Holiday Inn in Clearwater Beach, Florida, from January 31 to February 4. The theme of the special science sessions, planned by Dr. George Gates (President of the ARO in 1988), will be Mechanisms of Disease.

Additional information may be obtained from: Dr. Allen F. Ryan, ARO Secretary-Treasurer, Div. of Head & Neck Surgery, V-112C, Univ. of California at San Diego, La Jolla, CA 92093; phone (619) 453-7500, ext. 3375.

Name That Lesion Results and Interpretation

(Continued from page 7)

The CT Scan of the posterior fossa was obtained with and without contrast. The radiologist's conclusion was: (a) "Large ill-defined low density lesion in the left cerebellar hemisphere adjacent to the cerebellopontine angle. There was associated effacement and displacement of the fourth ventricle to the right..."

A second CT Scan was obtained two days later using a different contrast material (metrizamide). The conclusion was the same: "findings consistent with an intra-axial mass involving the left side of the cerebellum and brainstem."

The patient underwent a left posterior fossa craniotomy the next day. A tumor was encountered approximately two centimeters deep within the left cerebellar hemisphere. A frozen section showed it to be a low grade (I-II) astrocytoma. Because the tumor extended toward the pons, further dissection was not done.

DISCUSSION

This case illustrates a number of important clinical points.

- 1) It is an example of a good working relationship between audiology and otolaryngology. The otolaryngologist made an appropriate referral to the audiology center and received a windfall of information back.
- 2) "Screening" audiograms done in some otolaryngology practices would have missed this lesion as the pure tone audiogram was normal. This would have exposed the patient to risk from surgery to his nose, as the surgeon would not have anticipated any anaesthesia problems, and/or future metastasis of the tumor. It would also have exposed the audiologist and the otolaryngologist to the risk of malpractice litigation.
- 3) Speech audiometry continues to be an extremely sensitive indicator of retro-cochlear lesions. Were we able to do this case over again, we would have made more extensive use of speech tests (PI/PB functions and SSI tests as a minimum).
- 4) Traditional low level tone decay tests continue to have poor yield in retrocochlear lesions. Again, were we able to do it over, we would have used a high level test like the S.T.A.T.
- 5) We think that the flagging acoustic reflex on the left side was probably a motor phenomenon related to the left cerebellar lesion.
- 6) The ABR is an extremely sensitive tool in identifying retrocochlear lesions. It even showed us the effects on the right side of brainstem displacement from the left-sided tumor mass.
- 7) Even when we're working under time pressure we should take a careful history. This patient volunteered nothing to us or to his otolaryngologist. We had to drag every diagnostic bit of information out of him.
- 8) Finally, it is important to LOOK CAREFULLY at the patient and not become too focused on hearing. As audiologists we should be as knowledgeable about the observable motor and sensory activity of the Central Nervous System as we are about the ear. In this case his diagnosis was clearly written in his eyes although his primary complaint was about his nose.

9th Annual Run...

Hearing Help Awareness Goal of 26-Mile Run by Health Care Providers

A 1987 "Run for Better Hearing" team of ear doctors, audiologists, hearing aid specialists, manufacturers, suppliers and researchers will each run 26 miles to focus public attention on available hearing help. They have entered the ninth annual Run set for June 20 at Grandma's Marathon in Duluth, MN, and they personally the interdisciplinary support for cost-effective public information projects of the Better Hearing Institute.

The Run is a fund-raising effort to strengthen BHI hearing awareness projects which have generated the equivalent of more than \$140,000 in broadcast time and print media space since 1973. BHI's program has been spearheaded by famous Americans who overcame hearing loss. They include Art Carney, Norm Crosby, Phyllis Diller, Nanette Fabray, Lou Ferrigno, Lorne Greene, Florence Henderson, Bob Hope, Arnold Palmer, Richard Thomas, Charlene Tilton, and many others.

As a warmup, BHI executive director Joe Rizzo will run his 43rd marathon in London, England on May 10. Then on June 22 Joe will be joined in Grandma's Marathon by hearing help providers from across the U.S. and Canada, including: Duncan Clifton, hearing industry supplier, Burlington, ONT; Robert Hanrahan, dispenser, Wilmington, DE; John House, M.D., otolaryngologist, Los Angeles, CA; Dr. Mead Killion, industry researcher, Chicago, IL; Dr. William McFarland, audiologist, Los Angeles, CA; Nita Rizzo, Joe's "better half," Springfield, VA; Dr. Steve Rizzo, audiologist, Chillicothe, OH; Dr. Richard Tomlinson, industry supplier, Burlington, ONT; Wayne Whitney, dispenser, Eau Claire, WI; and Michael Winship, hearing aid manufacturer, Minneapolis, MN.

STEERING COMMITTEE

Organizing and coordinating this year's campaign is a steering committee that includes Al Bruce, chairman, Starkey; Robert Tischbein, co-chairman, Starkey; Jim Anderson, Qualitone; Pat Koepke, Dahlberg; Jerry Miland, Starkey; and Bud Raas, Earmold Design.

MAJOR CONTRIBUTORS

Key Run supporters to date include: Activair/Duracell, American Academy of Otolaryngology—Head and Neck Surgery, American Auditory Society, Argosy, Audio-Aid, Beltone, Bernafon, Best Labs/Fidelity of Florida, Dahlberg, Danavox, Emtech, Eveready, Fidelity Hearing Instruments, Finetone, Hearing Instruments magazine, Hearing Journal, Hearing Services Inc., Hearing Technology Inc., Knowles Electronics, Lang Hearing Instruments, Linear Technology Inc., Maico, National Hearing Aid Society, Omni Hearing Systems, Oticon, Phonic Ear, Qualitone, Ray-O-Vac, RCI, Starkey, Telex, U.S. Counseling Services, and Wilbrecht.

1987 AAS Convention to be in Chicago

For AAS members September 21st will be a day of exciting intellectual stimulation and a night of equally exciting entertainment.

This year the meeting will be held at the Inn of Chicago. Between President LaVonne Bergstrom's introductory remarks at 8:30 a.m. and the close of the sessions around 6:00 p.m. there will be numerous scientific papers of the usual high quality. Special highlights will include Dr. Peter Dallos' Carhart Memorial lecture entitled "Neurobiology of the Cochlea: Hair Cells as Receptors and Motors", and the presentation of the Beltone Distinguished Teacher of the Year Award.

The "business" of the evening will be to indulge one's hedonistic tendencies. This will be easy to do aboard the 'Star of Chicago', wherein members and guests will cruise Lake Michigan, dine like lords, visit, flirt, gossip, etc.

The host hotel, the Inn of Chicago, is located in the Windy City's Miracle Mile amid many of Chicago's best known attractions. Nearby are the Hyatt Regency and Marriott hotels, which will be hosting the AAO-HNS annual meeting

Peter Dallos, Professor of Speech and Audiology at Northwestern University in Evanston, Illinois.

between the dates of Monday, September 20th through Thursday, September 24th.

September 21st, 1987, deserves a check mark on everyone's calendar.

Aural Rehabilitation Forum

Editor's Note: The following segment of the AR Forum is taking a little bit of a different slant. This interview-style article was generated with the assistance of Ginny Fickel, President of the Acoustic Neuroma Association. As a former neuroma patient herself, Ms Fickel understands the needs of others with this disorder. The Acoustic Neuroma Association is a patient-headed, peer support group, which grew out of an interchange among patients who felt the need for a support and information network.

AAS and the staff of Corti's Organ would like to thank Ms Fickel for informing all of us about her Association.

1) When did the Acoustic Neuroma Association (ANA) begin?

It was incorporated in April, 1981. There were a few dozen of us acoustic tumor "alumni" at the time who had found each other.

2) What prompted its creation?

After my tumor was removed in November, 1977, I had total facial paralysis, dry eye, exposure keratitis, and other residual problems. I really wanted to talk with others who had been through this experience, but knew of no one. During the following two years I found a handful of others, and we benefited from sharing with each other. All felt that a broader-based mutual aid group would be worthwhile, so the Acoustic Neuroma Association was incorporated to serve those affected by acoustic neuroma. Membership in a group of those with similar experiences can be helpful to patients, as well as to family members and to interested medical personnel.

3) How has it grown — both in numbers and services offered?

Today we have a mailing list of 2700. There are sister organizations in Canada and Australia, and one now being formed in Germany. We have members in all states except Montana and Wyoming.

ANA has published 23 quarterly newsletters of professional quality featuring physician-authored articles and self-help information. We also sponsor an annual symposium with physician speakers, workshops for special concerns, and overflowing camaraderie; offer the opportunity to network with other "alumni" in one's own locality; and assist with setting up local meetings and groups. (Twenty "chapters" have formed in the past three years in all parts of the U.S.)

4) Are your goals still the same?

Yes, our goals still remain. They are:

- To provide support and information for patients who have experienced acoustic neuromas or other tumors affecting the cranial nerves.
- To furnish information on patient rehabilitation to physicians and health care personnel interested in the treatment of benign tumors and in the alleviation of post-surgical problems.
- To promote and support research on the cause, development, and treatment of acoustic neuromas and of other benign cranial tumors.
- To educate the public regarding symptoms suggestive of acoustic neuromas, thus promoting early diagnosis and consequent successful treatment.

5) What are group activities?

I have mentioned the annual symposium and local groups, which tailor the frequency of their meetings to their own desires. Most meet several times yearly, providing an opportunity to have "face to face" contact, and to hear informative lectures by physicians.

Our symposiums have been held in Hershey, Nashville, Ann Arbor, Los Angeles, Little Rock and, this year, Boston. All have been planned and arranged completely by volunteers. Physician speakers volunteer their time and expertise.

Symposiums have grown to two full day affairs and are attended by "alumni" from all parts of the U.S.

ANA grants financial help to 15-20 people to enable them to attend. This year about half of those receiving financial aid will be deaf because of bilateral tumors.

The Association has published a 12 page booklet, "Acoustic Neuroma", which is a comprehensive discussion of this disorder geared to the layperson. Many physicians give this booklet to their patients. ANA also publishes a quarterly newsletter, Notes, which provides professionally authored medical information, self-help aids, and relevant articles on a variety of subjects.

6) What is your organizational structure?

ANA is staffed entirely by volunteers. Our national office has six regular volunteers, and a dozen occasional others who help to prepare our quarterly newsletter mailing.

We have an Executive Board made up of four officers and several committee chairpersons; all except one has had an acoustic neuroma removed. We meet during the winter, and board members assume their own expenses. I can't say enough about volunteers and what can be accomplished by them.

7) What do you hope to achieve as an organization?

We would like to assist in alerting all ENT specialists, as well as audiologists and other primary care physicians, about the possibility that an acoustic tumor might cause a one-sided hearing loss.

Also, ANA is working on a system whereby potential members will be acquainted with the Association and its services.

8) Is presiding over this organization a full time job?

That and more. As is true of most commitments, the responsibility grows as the services and people served expand. We exhibit at ENT, neurosurgery, and some nursing meetings, and this, of course, is a part of the job which increases the time commitment.

Name That Lesion

A Forum for Case Studies

Edited by

Matthew W. F. Smith

As practicing audiologists, we encounter many interesting and unusual cases regularly. You know, that one really interesting case out of a hundred mundane encounters which piques your interest and makes the routine stuff endurable. While most of these unusual cases would not be considered deathless prose suitable for juried journals, they usually teach us something and may be helpful to our colleagues. As practicing clinicians, we have hundreds of thousands of wo/man-hours of clinical experience among us. With that in mind, the editors of *Corti's Organ* have created this forum for case presentations. This is YOUR clinical forum. Without your input it will perish. Let's hear from you today. Please send your clinical case experiences to:

NAME THAT LESION
c/o The Cybersmith
605 Burma Drive, NE
Albuquerque, NM 87123

This issue's case is AGAIN presented here by the editor from his private practice experience, which although extensive, is not infinite. Future case presentations will be from your clinical experiences. We need YOUR input!

CASE NAME:

The Case of the Silent Tinnitus

PRESENTER:

Matthew W. F. Smith, M.Sc., CCC-A

ADDRESS:

Hearing Evaluation Center
612 Encino Place, NE
Albuquerque, NM 87102

This is the sad tale of E.B., a 75-year-old female patient who had been recently diagnosed as having terminal cancer of the liver. Her life expectancy was very short.

Three weeks prior to her visit to us, she had undergone exploratory surgery which had confirmed that cancer was present and that it was advanced beyond surgical treatment. During the week following surgery, she experienced a sudden, severe loss of hearing on both sides.

She was referred by her internist to an otolaryngologist. His physical examination was unremarkable and she was referred to us for an audiological evaluation. His concerns were possible post-operative insult to the cochlea, or worse, new metastatic sites of the cancer.

We questioned the patient and her family about trauma, tinnitus, prescription medications and even chemotherapy. She denied

Continued on page 2

PLAN AHEAD

19th INTERNATIONAL CONGRESS

JERUSALEM, ISRAEL, JUNE 5-9, 1988

Name That Lesion

Continued from page 1

trauma or tinnitus; was taking no prescription medications; and was not on a chemotherapy regimen.

Pure tone audiometric test results showed her to have a fairly flat bilateral sensorineural hearing loss averaging 50 dB HTL. Speech thresholds were in approximate agreement with the pure tone results. Word intelligibility scores at MCL were good on both sides (See Figure 1).

Because of probe seal difficulties due to ear canal geometry, only screening tympanograms could be obtained. Tympanograms were of

Type A (normal) configuration on both sides.

This scant information prompted us to ask just one more clinical question which clarified the picture.

WHAT WAS THAT QUESTION, AND CAN YOU NAME THAT LESION?

RESULTS AND INTERPRETATION

It should be fairly obvious that advanced liver cancer and a post-operative wound are both very painful. What we failed to ask the patient during the first round of questioning and subsequently asked was, "What are you taking for the pain?"

This was the magic question. Her answer was: "Aspirin" and lots of it, too; four 500 milligram tablets, six times a day!

The etiology then seemed pretty clear to us. Salicylate poisoning. The only thing missing was the tinnitus, which is usually the hallmark of this condition. We'll speculate on that in a moment.

We recommended to E.B.'s physicians that the aspirin be discontinued immediately, and that an alternate analgesic be prescribed. We also recommended a follow-up evaluation in two weeks.

On follow-up, two weeks later, her hearing sensitivity and SRTs had returned to well within normal limits bilaterally. Her word intelligibility scores were excellent at 40 dB SL on both sides as well (See Figure 2).

She had completely recovered her hearing and was able to communicate effectively with her family until her death a few months later.

DISCUSSION

Well, what about the tinnitus, or lack thereof? I suspect that there probably was tinnitus present. However, I think that the patient's distressed state of mind over her cancer and imminent demise, the extreme pain she must have been in, as well as the frightening sudden loss of her ability to communicate, pushed noises in her ears way down on the scale of

AR Forum

Continued from page 1

9) Why are you doing this?

First of all, it's a privilege to be doing something which seems to be making a positive impact on people where formerly help was not available.

Secondly, seven months after my surgery my husband had a grand mal seizure, and a CT scan identified a cranial mass. It was a meningioma and was removed successfully. We really were the "unlucky/lucky" and felt that we should respond to the message which was being sent! My time, energy, and financial commitment to ANA has my husband's full support.

10) How would someone obtain more information about ANA?

Matthew W.F. Smith

importance to her. So much so, that it didn't come out even in response to a direct question. What can we learn from this simple but interesting case?

- 1) Aspirin poisoning is more common than most people think. The 500 milligram "Extra Strength" tablets are a contributing factor.
- 2) Hearing loss from aspirin toxicity is almost always reversible.
- 3) It frequently mimics presbycusis and is seen most often in the age range where presbycusis is expected. Watch out!
- 4) Questions about aspirin use should be a routine part of the hearing history for all patients, not just those complaining of tinnitus (it's part of ours now).
- 5) Be skeptical about answers to your history questions which don't make sense. Poke and prod until they do.
- 6) Don't assume that someone else in the referral chain will necessarily ask the important questions. It's your responsibility to gather data, history included, that make sense. In this case if the audiologist hadn't asked the "magic" question, very possibly an inappropriate and completely unnecessary hearing aid fitting may have been recommended.
- 7) Even though this patient's life span was to be very short, the quality of her last days of life was immeasurably improved because someone asked the right question. Let's be careful out there!

From the Editor...

I want to take this opportunity to thank all of you who took the time to express your feelings regarding the new segments we began with the last issue of *Corti's Organ*. When the editorial staff creates new columns, we are never sure what our readers' reactions will be. With both "Audiology Trivia" and "Name that Lesion", we seem to be faring pretty well. Thanks to all of you who responded so positively. Now, your next task can be to submit copy to these columns.

— Virginia Berry
Editor

Letter to the Editor...

Dear Ms Berry,

I want to commend you on the introduction of the new column entitled "Name that Lesion". It was a real cliff-hanger! It is true that we don't often come across cases involving good "detective work", and it is refreshing to see how others handle the situation. I learned a few pointers about observing eye movements and once again have had my faith renewed in the significance of our profession.

I hope to see more of the column in the future.

Sincerely yours,
Toni Gordon
Forest Hills, NY

Audiology Trivia

Edited By
Matthew W. F. Smith

A remarkable phenomenon of the 1980's has been the tremendous interest in trivia of all types. It became apparent to us that the field of Audiology, which has its roots in multiple disciplines, is a virtual cornucopia of trivial material. We are pleased to present *still more* Audiology Trivia. We invite your participation in this new American tradition. Please send your interesting Audiology Trivia along with a reference source to:

AUDIOLOGY TRIVIA

c/o The Cybersmith
605 Burma Drive, NE
Albuquerque, NM 87123

We will acknowledge your contribution in this column. Now let's play AUDIOLOGY TRIVIA:

TRIVIA QUESTIONS:

- Q1: What national audiology newsletter editor spent the night of May 15, 1987, with the Little Rock, Arkansas Vice Squad?
- Q2: In what country was Raymond Carhar born?
- Q3: Who first suggested what was to be known as the Valsalva maneuver and when?
- Q4: What phenomenon, described by Willis in the 1600's, bears his name?
- Q5: What psychophysical method is synonymous with method of right and wrong cases?
- Q6: What function does the aroma of cerumen serve?
- Q7: Where were the Mercury astronauts taken for hearing evaluations?
- Q8: Which earmold laboratory has a logo which depicts its involvement in the U.S. Space Program?
- Q9: What is the spectral slope of pink noise?
- Q10: What's another name for poststimulatory threshold shift?
- Q11: What structure is known as the vestibular gallery?
- Q12: Who is best known for his five 'bumps'?

See Answers on page 6

ERRATA

Gail Neely, M.D., an Executive Committee candidate was erroneously pictured under Industry Representatives instead of under Otolaryngology in the Spring 1987 issue of *Corti's Organ*. The editors sincerely apologize for any confusion that may have resulted from this printing error.

Meeting Abstracts

Application of Multiple-Frequency Tympanometry and an Audiometric Gelle' Test to the Differential Diagnosis of Middle Ear Disease

David J. Lilly, F. Owen Black,
and Robyn E. Holman
Good Samaritan Hospital & Medical
Center
Portland, Oregon

Clinical tympanometry usually is accomplished using a low-frequency probe tone. In our experience, these single-frequency (226 Hz) measurements yield diagnostic information that is quite adequate for about 85% of our patients who presently have middle ear disease. For the remaining 15%, however, a more sophisticated multiple-frequency tympanometric approach is required. This tympanometric data becomes even more useful, however, when we can measure the transmission characteristics of the ear, along with its input acoustic impedance, for the same range of air pressures.

In this presentation we shall describe the results of a pilot study that was designed to compare tympanometric data with psychophysical threshold data obtained using a modification of the Gelle' test. For this latter procedure we evaluated the effects of air pressure in the external auditory meatus on hearing by air conduction and by bone conduction. We used a 500 Hz test tone and the same range of air pressures that we planned to use ultimately for multiple-frequency tympanometry (+ 500 mm H₂O). Twenty subjects with normal hearing, 20 patients with surgically confirmed stapedial otosclerosis, and 10 patients with other middle ear problems were evaluated.

A review of our total pilot study suggests that: 1) The Gelle' test does not require complex instrumentation. It can be done easily with minor modification to existing clinical acoustic impedance systems. 2) Evaluation of Gelle' data and tympanometric data obtained at the same frequency can provide the information needed to develop dynamic models for normal and diseased middle ear systems. 3) Asymmetries in air conduction Gelle' patterns probably are reflected in tympanometric data generated at the same frequency; and 4) a diagnostic protocol that combines selected Gelle' data with multiple-frequency tympanometry has good potential for increasing the accuracy of diagnosis for patients with clinical otosclerosis and other diseases that affect the ossicular chain.

Diagnostic and Prognostic Value of Direct Promontory Bone Conduction in Patients with Otospongiosis

Mariola Sliwinska-Kowalska
and Bozydar Latkowski
Academy of Medicine
Lodz, Poland

Conventional bone conduction audiometry does not allow an objective assessment of hearing in patients with otospongiosis. We evaluated a novel method of direct bone conduction audiometry with the stimulator applied to the promontory intraoperatively. A comparison of conventional and direct bone conduction audiometry thresholds was made in 100 patients in various stages of otospongiosis before stapedectomy. A significant correlation between hearing thresholds obtained by both methods was observed for all frequencies tested, 500, 1000, 2000, and 4000 Hz ($p < 0.001$). The direct bone conduction method was at least 30 dB more sensitive for all frequencies. Interestingly, the average direct bone conduction threshold curve did not exhibit a Carhart notch at 2000 Hz as did curves generated by the conventional method. The actual "early" improvement of hearing thresholds following stapedectomy was demonstrated in 100 patients 2-3 weeks following the operation. The direct bone conduction technique was usually more predictive of hearing improvement following stapedectomy than was conventional bone conduction audiometry. We suggested that the direct bone conduction method for assessing hearing in patients with severe otospongiosis is superior to the conventional bone conduction technique, which often does not reflect actual cochlear reserve.

Determination of Ear Canal Length Using Acoustic Signals

C. Daniel Geisler and Joseph C.K. Chan
University of Wisconsin
and Project Phoenix, Inc.
Madison, Wisconsin

A direct optical method of measuring ear canal length was compared with an acoustical method. The optical method, adapted from Zemlenyi and associates, determined the distance from the posterior edge of the ear canal meatus to various points on the ear drum, such as its dorsal-most point and the attachment of the umbo of the malleus. The acoustic measurement system (using the Aurora™) used probe-tube measurements of sound pressure level (SPL) instead of frequency obtained at two different points in the ear canal. The difference between the two SPL measurements, which had in common the overall characteristics of the ear canal, showed in almost all cases a clearly defined anti-resonance (sometimes called the "quarter-wavelength" null) in the 6-10 kHz range. Using this anti-resonance, the distance from the ear canal entrance to the effective reflecting surface of the drum was inferred. Present data, on an initial sample of 10 people, indicate that effective ear canal length inferred from the acoustic measurements falls between the optically measured distance to the dorsal-most point of the drum and that measured to the attachment point of the umbo. Implications of the results concerning the accuracy with which ear drum SPL's can be inferred from measurements made at remote locations will be discussed.

Perilymph Fistulas in Children with Progressive Sensorineural Hearing Loss

F. Blair Simmons
Stanford, California

Perilymph fistulas (PLF's) sometimes occur in children with unexplained progressive unilateral or bilateral sensorineural hearing loss. Upon repair, occasional and sometimes dramatic hearing improvements have been documented. However, such outcomes are not universal; nor is it yet possible to know which child has a PLF without exploratory surgery — sometimes on an only hearing ear. This paper is an interim report on 24 consecutive explorations for PLF in children with progressive hearing losses (average progression, about 38 db, between 500 Hz and 2,000 Hz). One-half had a PLF, and some of these were bilateral. Hearing improved (+ 15 db at three contiguous frequencies) or the progression stopped (+ 5 db) in nine proved PLF's, but similar outcomes were found for nine negative explorations in which the oval and round windows were also grafted. Progression continued in two with PLF's and in four without PLF's. Furthermore, five ears were re-explored, whereupon two were found to have a PLF on the first operation but not on the second, and two were found to have a PLF on the second but not on the first surgery.

This small series needs longer follow-up, and the role of PLF's in contributing to progressive hearing loss is by no means clear. There are problems, including inadequate data on progressive hearing losses themselves, the uncertainty as to the incidence of PLF's in the absence of hearing loss in children, PLF intermittency (re: negative explorations), and our lack of technical ability to maintain a seal of the oval and round windows once a PLF has been demonstrated.

Narrow Band Digital Filtering of the Auditory Brain Stem Response

Roger R. Marsh
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Narrow band digital filters have been endorsed for reducing noise (and signal) outside the frequency band that defines the individual waves of the brain stem response. This approach had previously been criticized by the present author (without empirical evidence) as posing the risk of introducing distortion or extraneous waves in cases where the response deviates from the ideal.

Two digital filters were compared to determine their effects on normal adult responses. The first was a convolutional filter similar to Moller's. The second was an FFT implementation of 500-1000 Hz filter. This was similar to that of Fridman and associates, but with a more limited passband. Responses of five adults to clicks at 80, 60, 40 and 20 dB nHL (two 2000-sweep responses per intensity) were processed by the two filters. Latencies were measured for waves I, II, III and V at 80 dB, and for wave V only at the other intensities.

For the major waves — I, III, and V — the convolutional filter gave very good agreement with the measures on the unfiltered response; latencies differed by one bin (0.1 msec) or less for 56 or 60 possible comparisons. For wave II, however, the error was greater than this for four of eight possible comparisons; and the digital filter generated a spurious wave II where none was unduly influenced by the large adjacent waves. The FFT filter was similar to the convolutional filter, giving only six errors greater than 0.1 msec out of 60 comparisons for waves I, III, and V, but yielding four errors in latency and two spurious waves for Wave II. Both filters often rendered wave identification difficult at low stimulus intensities; in such cases wave numbers were assigned by reference to the unfiltered response.

It does appear that narrowband digital filters preserve latency information in the case of clearly defined responses, but that the potential for distortion and error remains in the case of small waves among large ones, or when there are adverse signal-to-noise ratios.

The Effect of Varying Frequency Response of an FIR Filter on the Slope of the Latency-Intensity Function

Kurt E. Hecox and Jennifer Patterson
Nicolet Audiodynamics
Madison, Wisconsin

For a number of years the slope of the wave V latency-intensity function of the brainstem auditory evoked response has been used to identify patients with inner ear disease. Unresolved is whether the slope changes are secondary to the high frequency slope of a hearing loss or secondary to other "unspecified" aspects of inner ear disease. To test this hypothesis, normal hearing listeners were evaluated with a filtered signal whose filter properties mimicked high frequency losses. In a second condition, a filter was designed to mirror the patient's audiogram and was interposed between patient and signal generation.

If audiometric contour were the primary determinant of abnormal slopes to the latency-intensity function, normal listeners with filters in place should produce abnormal slopes, and the hearing impaired with "corrective" filters in place should produce normal latency-intensity functions. Neither of those outcomes was observed in testing 10 normal hearing and 10 hearing impaired listeners. From these observations we conclude that the audiometric contour is not the sole or even the primary determinant of the slope of the latency-intensity function.

Spectral Analysis of ABR's from Patients with Cochlear and Retrocochlear Hearing Loss

Lynn G. Spivak
New York University Medical Center
Bellevue Hospital Center
New York, New York
and
Rochelle L. Malinoff
New York Eye and Ear Infirmary
New York, New York

There has been speculation that the ABR may contain pertinent information about the auditory system which is not readily apparent when analysis is limited to measurement of peak latencies and amplitudes. A recent report by Hall suggests that the spectral content of ABR's of head trauma patients may be abnormal, in spite of the fact that peak latencies and amplitudes are normal. The purpose of the present study was to investigate the potential contribution of spectral analysis of the ABR to diagnosis of auditory pathology.

ABR's were recorded from 97 subjects using 60dB SL rarefaction clicks presented at 11/s. Spectral analyses were performed on the ABR's of subjects with normal hearing (n=40), subjects with cochlear hearing loss (n=43), and subjects with surgically confirmed acoustic tumors (n=14). ABR's from subjects with cochlear and retrocochlear hearing loss were judged to have fair to good morphology. Ninety-five percent confidence intervals were calculated for the three major energy peaks in the spectra of normal ABR's. The frequency of these peaks agreed well with published literature. The spectral content of ABR's from ears with cochlear and retrocochlear lesions was compared to the normative data.

Spectral abnormalities involving at least one peak were present in the ABR's of 86 percent of the acoustic tumor patients. The largest proportion of abnormalities involved P2. Spectral abnormalities were considerably less frequent in the ABR's from ears contralateral to the acoustic tumor and in ABR's from ears with pure cochlear lesions. The results suggest that spectral analysis of the ABR may contribute to the differential diagnosis of auditory pathology.

Effect of Hypothermia on Auditory Brainstem Response in Man vs. Rat

James W. Hall III, Joan M. Bull
and Leslie H. Cronau
University of Texas Medical School
Houston, Texas

The effect of low body temperature (hypothermia) on the auditory brainstem response (ABR) has been repeatedly demonstrated in animal models and in the clinic. Latencies of ABR wave components increase exponentially as temperature decreases. Latency increases are greater for later waves (e.g. wave V) than for earlier waves (e.g. wave I). Less well studied is the effect of hyperthermia on the ABR. Gold and associates recently found decreased ABR latency and amplitude with elevation of body temperature in rats. There are no clinical reports of ABR and hyperthermia. We compared the effect of whole body hyperthermia on ABR latency and amplitude in man vs. rat.

ABR's were recorded during whole body hyperthermia with similar instrumentation and test protocol for 10 human subjects and 10 rats. Stimuli were clicks presented monaurally via Etymotic transducers and eartips for man, and a miniature receiver with plastic tubing secured in the external auditory meatus for rats. The response was detected with disk electrodes for man and with needle electrodes for rats, placed at the high forehead (positive) and earlobe (negative) positions. Core temperature was measured with a rectal thermistor.

Latency decreased as temperatures increased for man and rat. Latency changes were greatest for later waves. Amplitude remained constant or decreased with increased temperature.

In man, latency and amplitude returned to baseline values with return to normal temperatures. Rats were heated until systemic failure occurred. At temperatures between 43 and 43.5 degrees C, ABR amplitude rapidly diminished

and the response was no longer detectable. Clinical and basic science implications of these findings will be reviewed.

Speech Audiometry with the Elderly

M.L. Matthies, R.C. Bilger,
and L.A. Proctor
University of Illinois
Champaign, Illinois

The validity of speech audiometry is questionable if a patient's willingness to respond affects the obtained word recognition score. Elderly subjects' volition to respond may be related to the criterion effects debated by Rees & Botwinick and by Marshall & Jesteadt. Possible effects that could cause the understanding of speech to be underestimated include inattention, lack of cooperation, and unwillingness to respond to difficult stimuli.

The present analysis includes several data sets with subjects from 18 to 81 years of age tested with the Speech Perception in Noise test (SPIN) at a variety of signal-to-babble ratios (+8 to -2 dB). All subjects were tested at a single presentation level calculated as 50 dB above babble threshold. The data sets included subjects from the SPIN standardization study (n = 128), a hearing aid experiment (n = 40), a study of older listeners (n = 60), and subjects from a study of word recognition in noise (n = 86). All subjects were required to respond to all of the SPIN items, and the experimenters did not continue testing until a response had been given.

Statistical analyses concentrated on the question of whether an age effect occurred for those subjects falling outside of the specified relation between high and low context items. The relation between high and low predictability sentences is independent of hearing loss and is so precise that the tester can be assured when a valid result has been obtained. Goodness-of-fit analyses indicated that older subjects were no more likely to exhibit response biases than were younger subjects. Valid results on the SPIN test are obtained with elderly subjects by virtue of its design and the demand to respond to every item.

Reasons for Obtaining Hearing Aids: Do They Relate to Subsequent Benefits?

H. Gustav Mueller
Letterman Army Medical Center
Presidio of San Francisco, California
and
Donald R. Bender
Office of the Surgeon General
Fort Sheridan, Illinois

The selection of the hearing aid candidate is most frequently based on the degree of the individual's hearing impairment. This is only one of many indicators, however, which may contribute to overall success with amplification. In a previous paper, we identified several factors that prompted hearing impaired individuals to obtain hearing aids (e.g., communication problems in noise, encouragement from spouse, media promotional material). Seventeen different contributing factors were established, and the subjects ranked the factors with respect to significance. These rankings were obtained from 300 individuals, and all subjects were then fitted with hearing aids. (Subjects received their hearing aids free of charge from the military. Therefore, payment for the hearing aid was not a relevant measure of motivation.)

In the present follow-up study, conducted a year after the initial hearing aid fitting, it was questioned whether the original reason for obtaining amplification was related to subsequent use or benefit. For example, would someone who had independently sought amplification for communication assistance report more benefit than someone who obtained a hearing aid only because he was instructed to do so by an audiologist?

Each subject was mailed a short questionnaire, and 234 responses were returned. The questionnaire consisted of eight items, allowing the respondent to rate use of, benefit from, and satisfaction with the hearing aid(s). A five-point continuum was used for each item.

Hearing aid use, benefit, and satisfaction results were categorized according to the original reasons stated by the subject for obtaining

amplification. While the groups were not matched for hearing loss, mean audiograms were relatively similar. It had been previously determined that three of the leading reasons for obtaining a hearing aid were communication difficulties in noise, encouragement from spouse, and advice from a medical professional (audiologist). Interesting differences and unexpected similarities regarding hearing aid use and benefit were noted among these groups. For example, the group that many would consider to be the best candidates for hearing aid use would be those individuals stating a need for a hearing aid because of communication problems in noise. This group, however, reported significantly less use of hearing aids than did the other two groups. A second unexpected finding was that the reported benefit and satisfaction from hearing aids was essentially the same for all three of these groups. This suggests that a perceived need for a hearing aid may not be a prerequisite for subsequent success, if appropriate encouragement and counseling is provided. Of the seventeen groups studied, greater satisfaction from hearing aids was reported from the group who sought amplification because of communication problems in primarily quiet listening situations. Paradoxically, these individuals reported the lowest use rate.

These and other findings of this survey suggest that it is difficult to predict benefit and satisfaction obtained from hearing aid use based solely on the patient's original reason for obtaining amplification. Importantly, these results indicate that successful hearing aid fittings occur frequently for patients who are not self-motivated to obtain hearing aids.

Characteristics of the Electrical ABR

Robert C. Fifer and Michael A. Novak
Carle Clinic Association
Urbana, Illinois

As the field of cochlear implant rehabilitation moves into the pediatric population, a need exists for objective tests to evaluate candidacy and to monitor performance. One such test is the electrical auditory brainstem response (EABR). Researchers use this procedure to obtain data regarding the status of the VIIIth nerve to determine potential benefit from the implant system. This matter becomes particularly important in the very young children with etiologies of hearing loss that detrimentally influence VIIIth nerve survival in addition to cochlear function. In this paper, we present some unexpected characteristics of the EABR recorded from a pediatric cochlear implant candidate.

The patient is a 2 year, 10 month old child who acquired pneumococcal meningitis at age 2 years 5 months. The resulting hearing loss was profound in degree with absence of response to auditory stimulation at 134 dB SPL measured in the ear canal. EABR measurements were obtained at the time of implant surgery

using a stainless steel needle electrode placed on the round window through a mastoid/facial recess approach to the middle ear. We used a Nicolet CA1000 to record the responses and a component somatosensory stimulator to deliver the electrical pulses. One hundred microsecond pulses were delivered to the round window at rates of 1, 2, and 13 per second. After finding the stimulation level that produced facial motion, the intensity was decreased to the minimum level and then increased in a series of steps to evaluate the EABR function.

A stimulation level of 17 milliamps (mA) (dial reading) was necessary to elicit facial muscle contraction. However, we made video recordings of the stapedius muscle activation at levels as low as 1 and 2 mA. A signal averaged recording was not observed until 4 mA. At that level, a vertex-positive peak appeared at approximately 3.5 msec. The wave at that latency demonstrated an intensity-amplitude growth function through 10 mA similar to those seen for acoustically elicited ABR's.

When the child was paralyzed with Tracrium, a non-depolarizing skeletal muscle relaxant, the morphology of the signal averaged response changed dramatically. Instead of the large wave and relatively low threshold, higher intensities were needed to elicit waveforms that consisted of two small amplitude waves (0.1 to 0.3 uV) at latencies of approximately 3.5 msec and 4.5 msec. Moreover, at high levels of stimulation further growth in waveform amplitude was not apparent.

It appears from these observations that the EABR elicited with a needle electrode is heavily contaminated with stapedial and/or facial muscle activity. In contrast to the unparalyzed waveforms, the actual EABR is of relatively small and constant amplitude. This finding represents an "all-or-none" phenomenon of VIIIth nerve excitation that does not change with increasing electrical stimulus intensities.

Electrically Evoked Middle Latency Responses in Man, Monkey, and Guinea Pig

J.M. Miller, M.J. Burton, and P. Kileny
University of Michigan
Ann Arbor, Michigan

Electrically evoked middle latency responses (EMLR) have been studied to assess their utility in the selection of candidates for cochlear prosthesis implantation. With promontory stimulation in humans, our studies indicate that the EMLR may be elicited by pulsatile electrical stimulation. The characteristics of the response are similar to those observed with acoustic stimulation in normal hearing subjects, and responses may be recorded uncontaminated by electrical artifact. Comparative studies in profoundly deaf patients indicate that the threshold of the EMLR is comparable

IVth INTERNATIONAL SYMPOSIUM ON AUDIOLOGICAL MEDICINE

The International Association of Physicians in Audiology (I.A.P.A.) will have its Fourth Symposium in Tenerife, Canary Islands, Spain, November 8-13, 1987.

The scientific program will include round table discussions with invited speakers, together with free paper sessions on the two main themes:

1. THE STATE OF THE ART OF AUDITORY EVALUATION

Overview and evaluation of the hearing impaired child, methods of investigating a unilateral hearing loss, audiological training for ENT surgeons.

2. IMAGING CONTRIBUTIONS TO AUDITORY DIAGNOSIS

Computed tomography; magnetic resonance imaging; brain mapping; auditory evoked magnetic fields; single proton emission computed tomography and its diagnostic applications in the anatomy of the auditory system, in diseases of the otic capsule, in sensorineural hearing loss of the cochlear type, and in the retrocochlear pathology of sensorineural hearing loss.

For further information, contact:

Dr. Jose J. Barajas
Perez de Rozas, 8

Meeting Abstracts

Continued from page 4

to behavioral electrical thresholds. On the average, behavioral thresholds are 5-10 microamps lower than EMLR thresholds.

EMLR's were compared in humans, monkeys, and guinea pigs implanted with scala tympani electrodes. Their characteristics vary as predicted by auditory evoked MLR's in these species. In acute guinea pig preparations, acoustically and electrically evoked MLR's were demonstrated to be quantitatively similar: latency and amplitude input-output functions are comparable. EMLR's in the guinea pig have also been compared for promontory, round window, scala tympani, and modiolar stimulation sites. Promontory stimulation was found to elicit EMLR's only variably, in spite of placing the electrode at times in indentations in the thin lateral wall bone of the guinea pig cochlea. Round window stimulation was found to be equal in effectiveness to scala tympani stimulation. Modiolar stimulation demonstrated the lowest threshold and the steepest input-output function. Thus, the dynamic range of modiolar input-output functions tended to be smaller than that for scala tympani and round window stimulation, reflecting electro-anatomical features of the inner ear.

The EMLR would appear to be an appropriate measure for evaluation of the excitability of the central auditory pathways with electrical stimulation in the prospective implant candidate. On the basis of animal investigations, it would appear that round window stimulation sites are clearly superior to promontory sites and may be equivalent to intracochlear sites in their effectiveness and reliability of eliciting EMLR's.

Comparative Study of Hearing Aids and Cochlear Implants in Children

Barbara A. Bell and Lisa L. Tonokawa
House Ear Institute
Los Angeles, California

The effects of ongoing training, maturation, and the "halo" effect on children with the 3M/House cochlear implant have long been concerns of many professionals. It is difficult to separate these factors to determine the benefit of the cochlear implant alone in the development of auditory skills. We compared the amount of auditory improvement with hearing aids to the amount of improvement with cochlear implants in 31 children who wear both devices. This was done by comparing improvements in their implanted ear to changes in their hearing aid ear. We found that unaided thresholds to warble tones and speech stimuli remained consistent from pre- to post-test sessions for both ears. Thresholds were significantly improved from pre-implant with a hearing aid to post-implant with the cochlear implant in the implanted ear. In the non-implanted ear, aided thresholds remained the same.

On the Discrimination After Training test, before implantation, the mean aided score was 1.4 for the implanted ear. With the implant, that score was 7.9. For the non-implanted ear, the aided mean score improved from 2.8 at pre-evaluation to 3.5 at the post-test. Average follow-up time was two years. On the Test of Auditory Comprehension, the pre-implant mean score for the implanted ear was 0 and improved to 1.2 with the implant. The non-implanted ear had a pre-implant mean score of 0.3 with little change at a follow-up (mean = 0.2).

The implanted ear improved more than did the hearing aid ear. The little improvement

measured with the use of a hearing aid for an average period of two years represents what might be expected from training and/or maturation. The much greater improvement with the cochlear implant is even more striking when we consider that the hearing aid results represent the preoperatively better-hearing ear. Since both ears of each child were subjected to the same training and experience, results indicate that the cochlear implant provides significant benefit beyond potential benefits with hearing aids over time.

Short Term Auditory Memory in a Patient with Cochlear Implant

Susan Jerger, Karen Johnson,
Rose Chmiel, and James Jerger
Baylor College of Medicine
Houston, Texas

Information processing theories represent speech perception as a sequence of events involving registration, encoding, storage, and identification of information. Within this theoretical framework, the role of short-term storage mechanisms is viewed as crucial for speech comprehension. Speech sounds arrive sequentially and must be held in storage until sufficient information accumulates for identification by higher level perceptual processes.

The aim of this research was to study short term auditory memory in a patient with a cochlear implant. These specific questions were addressed: Does electrical stimulation of an impaired auditory system produce a memory trace in short-term auditory memory that aids processing? If yes, is this electrically induced memory trace differentially vulnerable to interference by new input as in normal hearing listeners?

The subject was a 36-year-old male with severe, bilateral, sensorineural hearing loss of approximately 6 years' duration. The loss had occurred after ototoxic drug therapy. The patient had worn a cochlear implant for 13 months. He

was considered a successful user.

The experimental tasks involved serial recall of auditorily presented digits. A stable characteristic of auditory serial recall tasks is superior recall for the last presented item, termed the "recency effect". A widely held assumption is that improved performance for the terminal item is due to the echoic component of short term auditory memory. The standard explanation is that immediately following list presentation, the last presented item continues to be represented in short term auditory memory and augments recall. Thus, the magnitude of the recency effect is an index of whether an echoic representation of auditory input is available to aid processing.

If an auditorily presented list is followed by an additional, irrelevant auditory item, the recency effect is selectively reduced. This effect, called the "suffix effect", is usually attributed to the erasure of echoic information. The precise conditions under which a suffix effect occurs have been explored as a means of studying the characteristics of short term auditory memory. For example, experimental findings have consistently indicated that echoic memory of spoken materials is not sensitive to meaning, but is highly sensitive to the speech-nonspeech distinction. Thus, the magnitude of the suffix effect for lists followed by an irrelevant speech item vs. an irrelevant noise should provide an index of how well the speech vs. nonspeech distinction is encoded by the cochlear implant.

The significance of the central auditory mechanisms underlying speech comprehension in patients with cochlear implants will be discussed.

Clinical Update: Speech Recognition Abilities of Nucleus 22 Channel Cochlear Implant Recipients Using the F0/F1/F2 Speech Feature Extraction Coding Strategy

A.L. Beiter, J.A. Brimacombe,
and M.J. Barker
Cochlear Corporation
Englewood, Colorado

Three month post-operative scores for Nucleus multichannel cochlear implant recipients were obtained on several speech recognition tests. The coding strategy used by all subjects was that which extrated from ongoing speech estimates of the fundamental frequency, first and second formants, and their respective amplitudes. The NU-6 word test was the most difficult, with a mean score for the group of less than 10 percent. Although CID Sentences and Iowa Sentences were somewhat easier (means of 20 percent and 24 percent, respectively), the variability in scores was large, with some subjects scoring 0 percent and others scoring greater than 50 percent on these sentence materials. Mean scores on all three speech recognition measures were significantly higher than those obtained with subjects using the earlier F0/F2 coding strategy.

In addition, speechreading abilities while using the cochlear prosthesis were significantly improved, as evidenced by a mean score of 31 percent on the Visual Enhancement subtest of the Minimal Auditory Capabilities Battery, as well as by a mean difference score of 30 words per minute (wpm) for two conditons of speech tracking ("speechreading + hearing" and "speechreading only"). For a subset of the group in which speech tracking "hearing only" was attempted, a mean tracking rate of 25 wpm

was achieved. Again, tremendous variability was seen with the lower 25 percent of subjects tracking at less than 17 wpm and the upper 25 percent tracking at rates higher than 40 wpm.

Seventy-one percent of the subjects reported using the phone, and of these, 50 percent recognized enough speech to use the phone interactively, i.e., without a code. Sentences developed at the Psycho-Acoustic Laboratory were administered over the phone interactively. These results will be presented in this paper.

Finally, longitudinal speech recognition scores on a subset of the subjects showed a consistent trend of improved performance over time. Both mean and individual data will be presented.

Auditory and Linguistic Performance in a Young Multichannel Cochlear Implant Child

Margery N. Somers
House Ear Institute
Los Angeles, California

In October of 1986, the Nucleus multichannel cochlear implant was approved for trials in children aged 2 to 9 years. The first young child in North America to receive this device, a five-year-old boy, was implanted at the House Ear Institute in February, 1987, 8 months after meningitis left him profoundly deaf.

This study is examining selected linguistic and auditory skills in three environmental contexts: classroom, therapy and home. Because this first child just received his device, the study is not yet complete. However, considerable data will be available by September of this year.

In this study the child's skills are assessed pre-operatively and reassessed monthly between April and September, 1987. Auditory skills will have been rated monthly by the child's teacher. The child's ability to respond to auditory stimuli in a classroom or therapy setting is being evaluated with a scale developed to assess awareness/detection, identification, discrimination, and comprehension.

Pre- and post-implant communicative interactions are videotaped to assess pragmatic functions of linguistic development, in particular, the discourse skills of topic initiation and topic maintenance. Discourse analyses are performed monthly with transcription of the video taped events. The number of initiations by the child are counted in relation to the total number of initiations by the child and his discourse partner. The number of contingent turns taken by the child are also noted. Monthly evaluations are done both in the home and in the school settings.

Since this child so recently received the multichannel implant, limited post-implant data are available. Pre-implant and one month post-implant findings follow.

Pre-implant data revealed no consistent auditory awareness or detection of sound or speech, and no discrimination or comprehension skills. Ratings were 1.0 (seldom/never) to auditory responses in all areas.

Post-implant data at one month showed consistent awareness and detection to sound and speech. Ratings were 1.8, revealing consistent responses above chance, but not at the 100 percent correct level. Discrimination abilities were consistent on specific closed set tasks (2.0). No comprehension skills were evident at one month post-implant.

Since loss of hearing, this child has been hesitant to initiate topics and has been unable to maintain a topic during communicative interactions in school and in home contexts.

At one month post-implant, increased attention skills in communicative interactions were evident. Topic initiation and topic maintenance

analyses showed increased skills in both pragmatic functions.

Functional assessment in varying environmental contexts can provide a different profile of abilities than can clinical evaluations, and is an important adjunct to the testing that is typically done. Comparison of pre- and post-implant results will help to define the full benefits of the multichannel cochlear implant.

San Diego was Site of ADA Meeting

The Academy of Dispensing Audiologists (ADA) held their annual meeting at the Princess Resort in San Diego, CA, from the 26th to the 29th of May, 1987. Members enjoyed the educational offerings of an impressive array of speakers and other participants, as well as the recreational opportunities which abound in the San Diego area.

A new feature of the annual conference was an evening devoted to forum-type discussions of various topics related to the business aspects of dispensing. These sessions focused on professional and product liability, marketing strategies, the value of marketing consultation, and the importance of referral sources to one's practice.

The keynote address of the conference was given by president-elect, John House, M.D. Dr. House emphasized the importance to audiologists of adequate physician awareness and of patient education.

Following this talk were panel discussions on the subjects of quality control in hearing aid manufacture and unfair competition from non-profit organizations. Finally, the program included a talk on professional burnout by Donn O'Neil (San Diego's Sharp Memorial Hospital), and a presentation on marketing by Kathleen Griffin (American College of Health Care Administrators, Bethesda, MD) and by Michael Pollack (Professional Hearing Services, Akron, OH).

In addition to providing stimulating lectures and discussions, the meeting afforded an opportunity to watch demonstrations on various procedures used in the modification of hearing aids. Bud Raas (Earmold Design in Minneapolis) and Tana Triantos (Siemens Hearing Instruments) coordinated this part of the program.

The ADA's next annual conference is scheduled for May 11-13, 1988, in Orlando, FL. The tradition of stimulating meetings is expected to continue.

Professionals Convene for Second Annual Children's Cochlear Implant Conference

A three-day conference addressing the progress and challenges of the multichannel children's cochlear implant program was held in Wild Dunes, South Carolina, June 19-21, 1987.

The conference, sponsored by the Denver-based Cochlear Corporation, focused on the need for extensive interaction among deaf education facilities and medical centers involved with the rehabilitation of implanted children. Participants concluded that a multi-disciplinary team of medical and allied health professionals is essential to ensure that children with cochlear implants are not left to cope with new sound sensation without comprehensive rehabilitation. Further, they concluded that parents need to be strong advocates of the mandatory special education granted them by law for their children.

Herman Jenkins, M.D., of the Baylor College of Medicine, Houston, chaired a surgeon's panel, which addressed the crucial issues associated with surgically implanting multichannel devices in children. Their discussions were directed towards anatomical considerations and surgical techniques unique to children.

The conference was attended by 100 professionals representing audiology, otology, deaf education, speech-language pathology, and allied health professions invited from clinical centers and educational sites across the country, as well as from Australia and England.

One paper, "Teaming with Educational Sites: Maximizing the Clinical Center/School Relationship", presented by Margery Somers, Ph.D.,

of the House Ear Institute in Los Angeles, communicated the importance of mainstreaming implanted children into public schools, but, stressed the need for continued special education.

Another paper, "Responsibilities of a Sponsor/Monitor and Investigator", delivered by Dave Segerson of the U.S. Food and Drug Administration, emphasized that participating centers should carefully follow the protocol to comply with FDA regulations and to evaluate fully the benefits of the Nucleus 22 channel implant for children.

In addition to round table discussions and case summaries, keynote speakers presented these additional papers: "Developmental Implications for Auditory Prosthesis", delivered by Ben Clopton, Ph.D., Kresge Institute, Ann Arbor, Michigan; "Growth of the Mastoid and Facial Recess", "Clinical Predictors of Spiral Ganglion Survival", given by Joseph Nadol, M.D., Massachusetts Eye and Ear Hospital, Boston, and "Speech Production Changes Following a Cochlear Implant: Implications for Children", presented by Emily Tobey, Ph.D., Louisiana State University Medical Center, New Orleans.

Work is currently underway to publish a synopsis of the round table discussions, as well as a summary of the surgeon's meeting.

For more information contact Dianne J. Mecklenburg, Ph.D., Cochlear Corporation, 61 Inverness Drive East, Englewood, CO 80112, 1-800-523-5798.

1986 AAS MEETING AVAILABLE ON VIDEOTAPE

The 1986 meeting of the American Auditory Society is now available on videotape.

The videotape is approximately 6 hours in duration. It includes the Carhart Memorial Lecture by Joseph E. Hawkins entitled

"TRACES OF AGE IN THE EAR AND THE EYE"

The videotape is available in VHS format only. To order, send the specified amount after checking one of the below:

- _____ I am sending a T-120 blank videotape. Please duplicate the 1986 convention tape and return it to me. Cost = \$25.00
- _____ I am not sending a blank videotape. Please send me a copy of the convention tape. Cost = \$35.00

Make check payable to the American Auditory Society.

Send order to: Michael F. Seidemann, Ph.D.
Jo Achim Eye, Ear, Nose and Throat Hospital
145 Elk Place
New Orleans, LA 70112

The videotape should be mailed to:

Please allow 4-6 weeks for delivery.

1987 Annual Meeting Big Hit

Nearly 250 people converged on the Inn of Chicago on Monday, September 21, for the 1987 annual meeting of the American Auditory Society. It was one of our largest turn-outs for a meeting held in conjunction with the American Academy of Otolaryngology.

Laszlo Stein of Michael Reese Hospital in Chicago served as Program Chair for the meeting. His Program Committee is to be commended for the excellent job done on the format of the program and on its organization. A series of outstanding papers was presented covering many contemporary issues of interest to all of us. A special tutorial session was scheduled entitled "An Update on Advances in Hearing Aid Technology". Experts from the fields of hearing aid fitting and research discussed significant issues relevant to amplification. The entire day was filled with dynamic and interesting papers, with quality time provided

for exchange of information among participants.

Certainly, one of the parts of this year's meeting that made it such a success was the Carhart Memorial Lecture delivered by Dr. Peter Dallos of Northwestern University. His topic, neuro-sensory development, was timely and most intriguing. A special treat was the presence of Mrs. Raymond Carhart as our guest at the special lecture given in tribute of her late husband. We were thrilled to have her with us.

The 1987 Business Meeting was also a highlight of this year's conference. President Bergstrom presided and welcomed everyone to our 14th Annual Meeting. Many special awards were given, including Ear and Hearing Editor's Awards and the Beltone Award for Distinguished Teacher in Audiology. (Articles

describing these may be found in this issue.)

The day of professional activity was topped off with an outstanding evening of dining, fun, and entertainment. David Hill, Chair of local arrangements, saw to it that our day did not end on a dull note. Society members and guests "let their hair down" on a gala cruise around the lights of Chicago on the Star of Chicago. A gourmet-delight of a buffet dinner was served. Participants then enjoyed dancing and revelry for the remaining time on board this wonderful ship. All who attended agreed that this was a perfect end to a perfect day!

Needless to say, this year's annual meeting will long be remembered by those who attended.

Those who didn't attend, wish now that they had. Now, it's time to count the days till Boston!!

Dr. Peter Dallos, 1987 Carhart lecturer and Mrs. Raymond Carhart who was a guest of the Society

Otolaryngology

Welcome New Executive Committee Members

The 1987 elections have been cast, and the new Executive Committee members are in place. All candidates were outstanding performers and helped to make this year's election a tough one.

Welcome aboard, new Executive Committee Members!

J. Gail Neely, M.D., F.A.C.S., Professor and Head, Department of Otolaryngology, College of Medicine, University of Oklahoma, Oklahoma City, Oklahoma. Fellowship, Otolaryngology, The Otolaryngology Medical Group, 1973-75. Otolaryngology residency, Baylor College of Medicine, 1969-72. M.D., University of Oklahoma, 1965. B.S., Biology and Chemistry, Central State University, Edmond, OK.

B. Hill Britton, M.D., Associate Professor, Section of Otolaryngology, The Bowman Gray School of Medicine, Wake Forest University, Winston-Salem, NC. Otolaryngology Fellowship, The Otolaryngology Medical Group, 1968. Otolaryngology residency, 1964-1968. M.D., University of Oklahoma, 1960. B.A., University of Oklahoma, 1956.

Neal C. Killion, Ph.D., President, Dynamic Research, Elk Grove Village, IL. Adjunct Professor of Audiology, Northwestern University, Ph.D., Audiology, Northwestern University, 1978. M.S., Mathematics, Illinois Institute of Technology, 1970. A.B., Mathematics, Wake Forest College, 1961.

Audiology

(Editor's Note: For those not familiar with the SHARE program, a description is included below).

Speech and Hearing Alliance for Resource Exchange

The primary purpose of SHARE is to assist in the international development of Audiology and Speech/Language Pathology training programs and services through the sharing of surplus textbooks, journals, reprints or other materials and resources.

A secondary purpose is to share experiences and information among persons with the common interest of helping the communicatively impaired.

The primary recipients of these resources are training or clinical programs located in developing nations that do not have the means to purchase journals and textbooks necessary for professionals who serve the communicatively handicapped in their countries. Individual requests for materials will also be honored.

Books, journals, and other materials are obtained through donations from individuals and libraries. Although more recent editions of textbooks are most useful, any edition can be of help as background information for beginning scholars and as a reference for more advanced professionals. In addition, recent volumes of professional journals serve as valuable resources.

The conduit for distributing these materials is the Communicative Disorders Foundation, a non-profit, tax-exempt foundation. The Communicative Disorders Foundation has obtained a start-up donation to cover expenses of forwarding materials to recipients. Additional grants and donations are being solicited. Gifts of books, journals, materials, or cash are acknowledged in writing by the Communication Disorders Foundation.

Suitable recipients will be forwarded materials appropriate to their stated needs. A stipulation of the exchange is that materials will be placed in libraries where they will be generally available to scholars.

Any donations of resources or letters of inquiry should be addressed to:

The President's Corner

Count Your Blessings and Your Decibels

This late summer and early fall I spent five weeks in China — my second trip there. I spent two weeks in Beijing attending the first International Otorhinolaryngology/Head and Neck Surgery Conference. After that we toured Xian, Shanghai and other cities. In Hangzhou when we toured a silk factory I pushed my tragus into my external ear meatus and for good measure folded my ear lobes over the tragus and kept them in place with my index fingers, which reduced the roar of the machines to a distant whisper. I used this technique everywhere we toured factories. On a flight to Jiuquan in the Gansu province I sat right next to the propellers and used the same technique, which interfered a little bit with picture-taking. Thus far I had conserved my hearing, which had been at or near zero dB all the way out to 8K Hz.

In the last city we visited on the Silk Road Tour, Urumqi, which is about 400 km from Russia, we had a lovely hotel with all the amenities. One "amenity" I will describe. Between the beds in all the hotels there is a console with controls for TV, radio, air conditioning, and lights. I did not notice that an alarm clock had been added. At 5:15 a.m. I came violently awake because a painful high

pitched crescendoing alarm went off. I hit the off button quickly, but immediately noted loud tinnitus in my right ear which was on the side of the noise. The head shadow *does* work. My left ear was OK, and several hours later the tinnitus subsided. The next morning the same thing happened only I couldn't find the button, so I faced the console and got a moderate dose of excess noise to my left ear before I found the right button pushed. I was rewarded with left tinnitus and recurrent tinnitus in the right ear also. I plan to write the Chairman of the Chinese Academy of Medical Sciences, who is an otolaryngologist and a member of the Communist Party, hoping that perhaps he can influence the Chinese to provide a more pleasant and safe wake-up call.

Hearing conservation is not practiced in China!

An audiogram today shows a 4K Hz dip to 20dB in the right ear and a 6K Hz dip to 30dB in the left ear. I am building up a supply of earplugs! The deficit at 8K Hz is 10dB in the right ear, 25dB in the left.

— LaVonne Bergstrom

From the Editor

With the close of this year's annual meeting and the completion of over eleven years of Society membership, I had a startling revelation. AAS has grown! That, by itself, is not so overwhelming. Our growth has not been in numbers alone.

What I find even more significant than increased attendance at meetings or doubled membership rolls is the reason behind the growth. Our interests are changing; our specialties are broadening. No longer are we simply a group of hearing professionals involved in diagnosis and rehabilitation. We have evolved into marketing experts, financial analysts, environmentalists, and much more.

As I looked around at the annual meeting, I saw many old faces but with new complexions. It was refreshing to see members who have

been involved with AAS since its creation, discussing new areas of involvement, but having just as much fun doing it. They did see the need to "re-invent the wheel" and many professionals often do. AAS has not been comfortable with standing still. It always challenged its members to add different dimensions other than those considered traditional.

This year, we had members travel to China; we had members affiliate with special interest groups; we had controversies addressed; we had members honored for accomplishments. I'm excited about what 1988 holds. I look forward to another eleven years as an AAS member. They're guaranteed to be filled with changes!

— Virginia S. Berry

Editorial Comments Concerning the Role of Medicare in the Hearing Aid Delivery System

By Matthew W.F. Smith, M.Sc., CCC-A

Editor's Note: The following was presented to the ASHA Legislative Council during the 1987 Annual Convention in New Orleans. Matt Smith, Features Editor for Corti's, welcomes your comments and feedback.

ASHA's governmental affairs group is currently lobbying Congress with a proposal to involve Medicare in the delivery of hearing aids. While at face value this would appear to be a noble thing to do, looking beyond the surface I see serious problems which could destroy the fiscal integrity of the Social Security Trust Fund, could almost certainly guarantee the lowest standard of hearing health care for the largest group of hearing impaired consumers, and, last but not least, could destroy the autonomy and economic feasibility of the private practice of audiology in America.

With our national debt soaring and the Social Security System struggling to keep afloat at current benefit levels, such a proposal seems fiscally irresponsible. I cannot see how Congress could even consider increasing benefits.

This idea becomes even more fiscally irresponsible when you consider the demographics of the twenty-first century. In the year 2010, the biggest population group in America, the Baby Boomers, will cross the Medicare threshold age. With presbycusis hearing loss a statistical certainty in ten to fifteen percent of this population group, I see a sudden demand for benefits that will almost certainly swamp the Social Security trust.

While the Baby Boom population surge into Medicare eligibility is a serious problem, more serious is the problem of the Baby Bust group, those born in the years following the Boomers. There is a population deficit in this group,

which should be paying into Social Security while the Boomers are drawing benefits from Social Security.

Increased benefits plus increased beneficiaries supported by fewer contributors is a formula for fiscal disaster.

A proposal which offers reimbursement of one hearing aid per person per three years would almost virtually guarantee failure of hearing aid use by a large portion of the beneficiary group. Since there would be no incentive to buy one aid now and another one in three years for the other most initial fittings would be monaural. Most presbycusis hearing loss is bilateral, symmetrical, and since we now know binaural fittings afford the best results, would be assuring substandard care. While the monaural hearing aid fitting is considerably less than perfect, it would likely add to the collection of horror stories of "how bad hearing aids are". As a result, second aid would not be purchased, and a negative attitude would be fostered and forced. Would you advocate a system of only funded the purchases of monocular binocularly symmetrical visual problems course not. Then why is ASHA advocating a proposal to encourage monaural hearing use with binaural hearing loss?

Further, the ASHA proposal suggests Congress would mandate a cap of \$500 for hearing aids. This is unacceptable today considering the overhead expenses incurred in private practice. With the next round of inflation, this would become an economic nightmare for the private audiologist.

This would stall research and development

Family Physician Targeted in New BHI PSA Featuring *L.A. Law* TV Series Star

Richard Dysart, starring in the top-rated NBC-TV drama series *L.A. Law*, appears in a new Better Hearing Institute television public service announcement encouraging hard-of-hearing viewers to benefit from available hearing help. The announcement is designed to increase the family doctor's awareness of his important role in helping people with hearing problems.

The PSA was filmed at the Santa Monica home of Dysart, who uses hearing aids himself to correct a hearing loss. Dysart plays senior partner Leland McKenzie on *L.A. Law*, which aired a special November 19th episode featuring hearing help. In the segment, McKenzie battled his vanity and admitted he needed a hearing aid when he went to court to fight an age-discrimination case.

BHI president Richard Burger said that Dysart's PSA, scheduled for February release to the major networks and local stations in the top U.S. markets, should be especially effective in inspiring others with hearing loss to benefit from available hearing help. He emphasized that the PSA benefits from marketing studies conducted by the Hearing Industries Association and the Institute, and supports other family physician projects being implemented cooperatively by both organizations.

Dysart's PSA is the latest in BHI's award-winning series featuring famous people who overcame hearing loss. Other PSA stars include Eddie Albert, Art Carney, Bill Cosby, Norm Crosby, Phyllis Diller, Nanette Fabray, Lou Ferrigno, Henry Fonda, Lorne Greene, Florence Henderson, Bob Hope, Jack Klugman, Arnold Palmer, Burt Reynolds, Richard Thomas, Charlene Tilton, and Keenan Wynn.

Editorial Comments

Continued from page 2

digital hearing aids which would initially exceed \$1000 per unit, wholesale cost. This would virtually guarantee that Medicare beneficiaries would get the *cheapest*, not necessarily the *best* hearing devices available. We owe our patients much more than that!

The ASHA proposal to Congress mandates a 30 day trial period with 100% refund if not successful. This offends me and worries me for three reasons:

1) The Federal Trade Commission, after years of testimony, including ASHA's, determined that a mandatory trial period and mandatory refund policy is not needed. Is ASHA making an end run around the FTC?

2) Hearing aid fittings which are acoustically perfect often fail because of patient motivation problems. A 100% refund would encourage frivolous trials, and implies that we should not be compensated for our time expended with the patient.

3) What other prosthetic device can be returned after trial? None. By mandating a return privilege for hearing aids, the implication is made that we don't know what we're doing with hearing aids.

Another concern of mine is that this proposal, which appears to attempt exclusion of the traditional hearing aid dispensers from Medicare, borders on an anti-trust action which could put ASHA at risk for litigation from the National Hearing Aid Society and others. Much as we dislike their existence, they have every legal right to participate in any governmental program.

Regarding professional autonomy, Medicare has placed the Speech-Language Pathologist in the position of technician, directed and supervised by physicians, who are least qualified to supervise. I do not want to see audiologists end up in this position.

Finally, our experience with Medicaid and other third party carriers suggests that the best way to economically cripple our profession would be to put 85% of our target market under government run insurance programs.

I have jokingly told my friends and colleagues that I'm taking home study courses in truck driving. If ASHA's proposal is successful with Congress, I'm afraid this will no longer be a joke.

Please rein in this proposal until the entire membership can consider it. Our patients' future care and our profession's future existence depend on you!

"L.A. Law" TV series star Richard Dysart discusses his BHI PSA script with Institute director Joe Rizzo.

Old AAS Friends Enjoy Reunion on Evening Cruise

Aural Rehabilitation Forum

A Family Systems Approach to Disabilities: The Hearing-Disordered and Alcoholic Families

Sharon I. Eve, MA, MFC
Alcoholism Center for Women
Los Angeles, California

Editor's Note: Ms. Eve is a psychotherapist in private practice in Playa del Rey, California, who until recently occupied a position as Director of Programs and Clinical Supervisor at the Alcoholism Center for Women. She currently serves on the Board of Directors of the Disabilities/Substance Abuse Task Force in Los Angeles, and has authored several articles on alcoholic family issues.

Loneliness, fear, anger, confusion, resentment. It has been noted in recent years (Wegscheider, 1980, 1981; Ackerman, 1983) how these feelings have come to appear in the alcoholic family system as alcoholism progresses. Through consultation between the author, a psychotherapist, and audiologists, it has become apparent that some similarities exist between the dynamics found in the alcoholic family system and in the hearing-disordered family in which at least one member is suffering an untreated and often progressive, acquired hearing loss. A systems approach will be utilized to examine the individual suffering from the disability, the family members, and implications for treatment.

Alcoholism and Acquired Hearing Loss

Alcoholism and hearing loss have many features in common as well as differences. Hearing loss may be, as alcoholism is, a progressive and chronic process which affects the physiological, psychological, and social status of the individual. The alcoholic suffers physical impairment as a result of excessive addictive consumption. The physiological consequences of drinking may include cirrhosis, cardiac arrest, elevated blood pressure, various forms of cancer, and pancreatitis. The hearing-impaired individual may suffer irreversible damage to the auditory system, whether the onset is abrupt (i.e., due to accident) or gradual.

Neither the alcoholic nor the hearing-disordered individual has voluntarily initiated the disease process. The hearing-disordered individual did not elect a hearing loss. The alcoholic may initially have chosen to drink, though he or she did not choose to become addicted to alcohol. However, both individuals may be in denial about the severity of their problem, how it is affecting them, and how it is affecting those around them.

Denial of the severity and consequences of the problem may be maintained by a number of factors in both cases, serving as an impediment to obtaining treatment. The alcoholic in our society is often seen as an unsavory, immoral, skid row character. The hearing-disordered individual may be seen as getting old, with all the implications this has in our youth-oriented society.

In addition, acknowledgement and confrontation of the problem, whether it be hearing impairment or alcoholism, has powerful implications for the individual. The alcoholic who stops drinking must begin to deal with life without the aid of his or her drug, cushion, or anaesthetic. The alcoholic in early recovery from alcoholism may need to develop coping skills to address the feelings and situations which arise. This is a long and arduous process. The hearing-disordered person, when acknowledging the severity of the hearing impairment and obtaining treatment (i.e., a hearing aid) is confronted with the body's aging process and his or her own mortality.

Entering the recovery process for the alcoholics and obtaining treatment for the hearing-disordered persons require that the impaired individuals address a difficult reality and begin to take responsibility for themselves, their disability, and their treatment/recovery. This may be a tremendous step, especially if family members, co-workers, or others close to the individual take up that responsibility.

The Family

Family systems theorists view the family as an operational system. Bowen (1973) has stated that "change in the functioning of one member is automatically followed by a compensatory change in another family member." To each action, there is an equal and positive opposite reaction within the family system.

Family systems operate with their own sets of roles and rules of behavior. Recently, these

roles and rules have been described as they relate to the alcoholic family system (Black, 1981; Wegscheider, 1989; Subby and Friel, 1984). Similar roles and rules may operate in the hearing-disordered family system as well. Examination of roles and rules in the alcoholic family may shed light on what is taking place between family members in the hearing-impaired family, and may offer implications for treatment approach.

A primary role in the alcoholic family system is that of the enabler. The enabler comes between the alcoholic and the consequences of his or her behavior. The enabler may rescue the alcoholic (in covert or overt ways), make excuses for the alcoholic, call in sick for the alcoholic. The enabling individual alters his or her life around the behavior of the alcoholic. Feelings that eventually arise may include loneliness, frustration, anger, guilt, resentment, and depression.

The enabler in the hearing-disordered family may come between the hearing-impaired individual and the consequences of his or her hearing loss. The enabler may speak in a louder voice, may avoid conversation with the hearing-impaired person, may avoid social situations, or may turn the television or radio up to louder levels. The feelings that may arise are similar to those of the enabler in the alcoholic family — loneliness due to decreased communication and contact, frustration, anger, guilt, resentment, and depression.

In both cases, the enabling behavior aids the impaired individual to continue to deny the severity of his or her problem and not obtain treatment, whether that treatment is in the form of a hearing aid or alcoholism treatment.

Other role patterns taken on in the alcoholic family, often by the children, may be applicable to the hearing-disordered family as well. These patterns include the sensible one, the adjuster, the placater (Black, 1981), or the family hero, the scapegoat, the lost child, or the mascot (Wegscheider, 1980). Children in the hearing-

disordered family may adopt similar compensatory or reactive roles in order to maintain a sense of balance or homeostasis in the family.

The alcoholic family is a system that appears to function in accordance with a set of rules. Subby and Friel (1984) have noted the following: (1) It's not okay to talk about problems; (2) Feelings should not be expressed openly; (3) Communication is best if indirect, with one person acting as a messenger between two others; (4) One should be good, strong, right, perfect; (5) Do as I say, not as I do; (6) It's not okay to play or be playful; and (7) Don't rock the boat. Similar rules may operate in the hearing-impaired family as well.

Treatment Implications

In the untreated alcoholic and the untreated hearing-disordered families, denial continues, communication worsens, and frustration and loneliness increase. Each individual in the system plays a part, and each experiences the pain of his or her position. Through our outreach, education, and treatment, a family systems view will allow us to serve not only the suffering hearing-impaired or alcoholic individual, but the family members who suffer as well.

Appropriate assessment of the family situation is needed. What part does each individual play in the dysfunctional family operations? How has each individual been affected? Feelings need to be validated, and healthier coping strategies need to be introduced for all members of the system who are affected.

Family members must come to understand the nature of their enabling behaviors. Enabling may be an obvious or subtle process. Understanding and change take time, guidance, and support. It is recommended that support groups be made available not only to hearing-impaired individuals and alcoholics, but to family members and significant others as well.

Literature in the form of pamphlets, articles, and books are now available to the alcoholic and to members of the alcoholic family. Educational information may be made available to

the hearing-disordered person and to family members about how the problem affects each one of them (not only the impaired individual). Information provided may help all involved understand their experiences, receive so validation for their feelings, and begin to address new, healthier coping strategies.

Education and treatment efforts must address the many aspects of an individual's life who are affected by hearing impairment or alcoholism, whether his or her own or that of a loved one. These include not only physiological aspects, but also the psychological and social states and the functioning of all persons involved in the system.

An interdisciplinary approach would help address the multifaceted effects of alcoholism and hearing disorders. The audiologist, otolaryngologist, and psychotherapist may work together to reach and treat families who suffer from hearing impairment as the physician, psychologist, and alcoholism specialists work together to serve the impaired alcoholic family.

Conclusion

The author has never worked with an alcoholic family in which the entire family sat down to dinner one evening and decided they all had a problem and would seek help together. Rather, one person reaches his or her limit of emotional pain and begins the treatment/recovery process. Thus the system begins to change. There are many roads into the hearing-disordered family. Whether the first to reach out for help is the hearing-impaired individual or a family member, adequate services must be available to the individual. In this way, hopefully, all members of the family system will eventually receive help needed to build more fulfilling and satisfying relationships with each other.

A family systems approach was discussed; it relates to the alcoholic and hearing-impaired families. It is recommended that an interdisciplinary approach addressing the physiological, psychological, and social aspects of the impairments be utilized in outreach, education, and treatment of all family members affected.

(NOT to Williams & Wilkins)

Minutes of the American Auditory Society Executive Committee

DATE:

September 20, 1987

PLACE:

The Inn of Chicago, Chicago, Illinois

TIME:

1:30 p.m.

MEMBERS PRESENT:

Virginia Berry, LaVonne Bergstrom, Patrick E. Brookhouser, Alison M. Grimes, Deborah Hayes, Robert W. Keith, Susanne Kos, David J. Lilly, Richard T. Miyamoto, James J. Pappas, David Preves, William F. Rintelmann, Ross J. Roeser, Michael F. Seidemann, Wayne J. Staab, Laszlo K. Stein, Don W. Worthington.

MEMBERS ABSENT:

F. Owen Black, E. Robert Libby, David Lipscomb.

GUESTS:

B. Hill Britton, Tomi T. Browne, William F. Carver, James R. Curran, Michael Dybka, Irvin Gerling, Mead Killion, J. Gail Neely, Ken Startt.

1. President Bergstrom opened the meeting at 1:45 p.m. She thanked the members of the Executive Committee for their attendance and recognized the new Executive Committee members in attendance. They were: B. Hill Britton, William F. Carver, James R. Curran, Deborah Hayes, Mead Killion, J. Gail Neely.

2. The minutes of the 1986 AAS Executive Committee meeting, held in Detroit, Michigan, were reviewed and approved.

3. The financial report for the period January, 1987, through August, 1987, was presented by Ross Roeser. Total revenues of \$44,806 and total expenses of \$75,880 were reported, resulting in a net deficit of \$31,074. However, it was pointed out that most of the income from dues was collected between August and December of 1986, thus explaining the paper-operating deficit. Overall, it is projected that the Society will operate at a profit for 1987. Assets included \$7,654 in the checking account and \$31,907 in savings, making the total assets \$39,561. Based on the financial condition of the Society no increase in dues was recommended for 1989. Following the report a motion was made and passed that there be no increase in dues for 1989.

4. Ross Roeser reported on the membership. As of September 1, 1987 there were 2002 members. Of this number 1,854 were regular members and 148 student members. The last five years have shown a very positive increase in membership as follows:

1983	— 1,337
1984	— 1,554
1985	— 1,702
1986	— 1,992
1987	— 2,002

A break down of the membership indicates that the majority (86%) of the members are audiologists with only 9% being otolaryngologists. It was recommended that the Membership Promotion Committee develop a strategy to attract otolaryngologists to membership in AAS.

5. Ross Roeser was appointed as Secretary/Treasurer for 1989.

6. Susanne Kos was appointed as Assistant Secretary for 1989.

7. Laszlo Stein gave a report on the 1987 meeting. He recognized the efforts of the local arrangements person, David Hill, and thanked the other members of the Program Committee. A motion was made to extend the appreciation of the American Auditory Society to Laszlo Stein for his efforts in planning the 1987 meeting. The motion passed.

8. In Frank Musiek's absence Michael Dybka reported on the plans for the 1988 meeting. The meeting will be held on Thursday, November 17th, in Boston. The annual meeting will be held at the New England Medical Center (Tufts Medical Center). An auditorium has been reserved that will seat between 300-460 individuals. It is within walking distance of the ASHA Convention hotels. The program committee is looking at the possibility of providing lunch with the registration fee. The possibility of having a poster session was also discussed.

During the discussion of the 1988 meeting, a motion was made to establish a permanent Program Committee consisting of past and present program committee chairpersons, and other members as seen fit. The motion passed. Don Worthington was appointed Chairman, and Laszlo Stein, Bill Rintelmann, and Frank Musiek were appointed committee members.

Michael Dybka and LaVonne Bergstrom were appointed as *ad hoc* committee members.

Other plans for the 1988 meeting were discussed. Modification of the call for papers was suggested so that abstracts of no more than 200 words would be included for publication in *Corti's Organ*, along with longer summaries. Possible Carhart lecturers were discussed and one individual was identified for the 1988 meeting. In addition, another individual was identified for the 1989 meeting. LaVonne Bergstrom will contact both individuals and invite them to be speakers for those meetings.

9. The 1989 meeting will be held in New Orleans in conjunction with AAO/HNS. Mike Seidemann was appointed as local arrangements chairman. Don Worthington, as Chairman of the Program Committee, will supply names for the Program Chairman for the 1989 meeting. Previously, the scientific meeting has been held on the Monday during the AAO/HNS meeting. The possibility of holding the meeting on Sunday was raised and it was voted to hold the meeting on Sunday, September 24, rather than Monday. The Executive Committee meeting will be held on Saturday, September 23rd.

10. Bob Keith gave a report on *Ear and Hearing*. He introduced Ken Startt, the representative from the Williams & Wilkins Company. Ken Startt indicated that circulation was up 10%, which he felt was highly favorable. He indicated that royalties from *Ear and Hearing* will be approximately \$22,000 for 1987. Based on all financial projections there will be no increase in the members' cost for *Ear and Hearing* for 1989.

Bob Keith began by announcing that Kathy Grauvogel had been replaced as Managing Assistant by Marie Christakos. He also indicated that Irvin Gerling, who has been Editorial Assistant, had been named Associate Editor. He reviewed the manuscript flow and indicated that the average time for acceptance is 5.2 months. Several suggestions were made to improve the appearance of *Ear and Hearing*. Finally, he discussed the future plans for *Ear and Hearing*. (The *Ear and Hearing* editor's report appears in full in a separate section of this issue of *Corti's Organ*.)

11. Virginia Berry reported on *Corti's Organ*. Susanne Kos continues to serve as Assistant Editor. Subject Editors include Frank Brister (Equipment/Material Review), Matt Smith (Features), and Karen Patterson (Clinical). Ms. Patterson replaces Bill Domico on *Corti's* Editorial Board. Virginia summarized the past year's activities of the publication and described new features to be included this next year, such as a Meeting Review Column. A 10th Anniversary Special Issue will be considered.

12. Standing Committee Reports were given.

Long Range Planning Committee — Ralph Naumton was not in attendance to give the Long Range Planning report.

Membership Promotion — Mike Seidemann reported on membership promotion. At the 1986 meeting the target population for the membership promotion was otolaryngologists. A letter was written, but has not been sent. Jim Curran and Alison Grimes were added as Committee Members.

Continuing Education — Deborah Hayes reported on the Continuing Education activities. She indicated that ASHA and NIHIS CE credit and CME credit were obtained for the 1987 meeting. An arrangement has been worked out so that AAS will not have to pay the normal \$150.00 fee for NIHIS credits. She recommended that AAS continue to offer CE and CME units for the annual meeting.

Qualifications — Susanne Kos presented lists of applicants for membership (the lists in their entirety are published following the minutes). There were 91 applicants for membership with sponsors, 30 applicants for associate membership, 128 applicants for student membership, and 18 applicants with no sponsor or one sponsor. After the lists were reviewed for membership a motion was made to accept the applicants and the motion passed.

13. Mike Seidemann reported on videotaping. He indicated that 55 copies of the 1986 meeting had been ordered. The quality of the tape was marginal, he felt, but acceptable. He indicated that there had been a problem in obtaining slides from speakers. He also indicated that it would be beneficial to purchase additional equipment for this activity. A motion was made to spend up to \$5,000 on additional video

equipment after the Executive Committee was polled by mail. The motion passed. Bill Carver was added to the Videotaping Committee.

14. Ross Roeser reported that AAS is now an incorporated non-profit organization in the State of Texas.

15. At the 1986 Executive Committee meeting Ross Roeser was directed to investigate the costs of having a separate membership directory. He reported that the costs of the directory would be \$5,500. The directory would include each member's name, professional address and affiliation, home address, membership category, and home and office phone numbers. After discussion, either having the membership directory published by Williams and Wilkins and sent out with an issue of *Ear and Hearing*, or

publishing the directory as a separate item, was recommended. (Following the Executive Committee meeting several members indicated that the costs of the directory appeared to be excessively high and recommended that the Executive Committee be polled by mail to explore keeping the directory in *Corti's Organ*, but expanding the information.)

16. Professional liability insurance was discussed. Mike Seidemann indicated a concern for the professional liability of AAS Executive Committee Members. Ross Roeser explored the cost of liability insurance and indicated that it would cost approximately \$5,000 for this type of insurance for AAS. A motion was made that

'You Should Hear What You're Missing'

Legendary golfer Arnold Palmer, who personally overcame a hearing problem, urges others to benefit from available hearing help:

Hearing the cheers of the gallery can be music to a golfer's ears. I can hear them much better now, since I got help for a hearing loss.

You know, nearly 20 million Americans with hearing problems needlessly miss life's precious sounds. Why needlessly? Because virtually all of them can *now* be helped—medically, surgically, or like me, with hearing aids.

If you suspect a hearing loss, or thought nothing could be done about it, ask your family doctor who can guide you. Thanks to significant advances in the hearing field, there are many hearing health care professionals who can help you.

So if you or someone you love doesn't hear well, arrange for a hearing test today. For hearing help information, call toll-free Hearing HelpLine at 800/EAR WELL.

Because you should *hear* what you're missing!

Better Hearing Institute

P.O. Box 1840, Washington, D.C. 20013

EXECUTIVE COMMITTEE

The AAS Executive Committee met on September 20th for its annual day of hard work and decision making. Old committee members, joined by those newly elected, spent hours around the conference table reviewing the year's business and discussing what next year might hold.

E AT WORK AND PLAY

Their hard work was rewarded with a terrific evening of dining and conversation at Chicago's spectacular 95th Restaurant atop the John Hancock Building. An overpowering view of the city was the perfect site to finish off the day!

Minutes

Continued from page 5

AAS self-insure and the motion passed.

17. LaVonne Bergstrom discussed the role of AAS with the 19th International Congress of Audiology. Moe Bergman extended an invitation to AAS to meet with the 19th International Congress of Audiology in Jerusalem in 1988. After discussion, it was decided that AAS would not have a formal program at the 1988 ICA meeting. Rather, AAS would support the ICA by announcing the meeting. David Lilly was appointed liaison to the ICA.

18. Reconsideration of the annual meeting duration was discussed by Mike Seidemmann. He indicated that the size of the annual AAS meeting had grown to the point that either having a two-day meeting or having a separate meeting might be considered. After discussion, it was felt that neither of these options was desirable at the present time.

19. Tomi Browne discussed the Council for Better Hearing and Speech Month. She and Lloyd Bowling have been co-representatives to the Council for the past year. She indicated that it was necessary for Lloyd Bowling to resign due to other commitments. She reviewed the activities of the Council for the past year and recommended that AAS continue to support the Council for the 1987-88 campaign. Membership dues are \$1,000. The Executive Committee thanked Tomi and voted to continue her as Chair of the Council for Better Hearing and Speech Month for the 1987-88 campaign.

20. Ross Roeser indicated that he had contacted a professional association management company to explore using them to manage AAS. Banks, Miller and Associates, located in Austin, Texas, submitted a proposal for \$12,000 per year plus costs. After discussion it was felt that this and other possibilities should be explored during the next year and that this

item should be discussed at the 1988 Executive Committee meeting.

21. The standing committees of the AAS were listed as follows:

Committee	Chair	Members
Continuing Education	D. Hayes	
Council for Better Hearing and Speech Month	T. Browne	
Long Range Planning	R. Naunton	D. Preves W. Staab
Membership Promotion	P. Brookhouser	J. Curran A. Grimes M. Seidemmann
Nominations	W. Rintelmann	J. Curran D. Lilly R. Miyamoto F. Musiek
Program Committee	D. Worthington	W. Rintelmann L. Stein (Ad hoc — L. Bergstrom, M. Dybka)
Qualifications	S. Kos	
Videotapes	M. Seidemmann	W. Carver

22. LaVonne Bergstrom recognized the efforts of the departing Executive Committee members and thanked them for their service. The retiring members are: F. Owen Black, E. Robert Libby, David Lipscomb, James Pappas, Mike Seidemmann, and Wayne Staab. As Vice President, Wayne Staab will continue to be an Ex Officio Executive Committee Member.

23. There being no further business the Executive Committee was adjourned at 5:50 p.m.

LaVonne Bergstrom, M.D.
President

Ross J. Roeser, Ph.D.
Secretary/Treasurer

Third Annual Scott Haug Audiology Retreat Held in Kerrville, Texas

The Third Annual Scott Haug Audiology Retreat was held September 24-27 in the beautiful Texas Hill Country. The Texas weather cooperated, and, with the participation of nearly 100 attendees and an outstanding faculty, three days of information and various group activities provided a fun and educational weekend. The Retreat provided over 13 hours of continuing education for audiologists, and hearing aid dispensers from a highly qualified group of presentors: David Lipscomb, Ph.D.; Geary McCandless, Ph.D.; Jerry Northern, Ph.D.; Ross Roeser, Ph.D.; Steven Staller, Ph.D.; Robert Traynor, Ph.D.; and Don Worthington, Ph.D. Group activities included golf, horseback riding, tennis, a team softball tournament, and a country-western fifties dance.

Annual Meeting Will Be One Not To Miss

Plans are already underway for the AAS 1988 Annual Meeting to be held in Boston, Massachusetts in December. This will be the first time the meeting has been held in the Northeast.

Musiek

In an interview with Virginia Davis, Frank Musiek, Ph.D., 1988 Program Chair, discussed some of the exciting preliminary plans for the meeting.

Question: Frank, what time and place arrangements have been made for the 1988 meeting?

Answer: The meeting will be held in Boston at the New England Medical Center Hospital on November 17, 1988. This is the Thursday before the ASHA Convention begins.

Question: With your office in Hanover, New Hampshire, at the Dartmouth-Hitchcock Medical Center, wasn't it difficult to have the meeting in Boston?

Answer: Not when you've got the kind of support team I have. Michael Dybka, Ph.D., from the New England Medical Center is the Local Arrangements Chair and is already busy planning many great activities in Boston. Mike and I have returned in discussion with people across the country that there is an abundance of interest in coming to Boston. Certainly, recent attendance is expected.

Question: Will the 1988 Annual Meeting follow the same format as previous Society meetings?

Answer: Much of the program will be devoted to contributed papers representing the research and clinical work being done by members of the Society. A call for papers will be mailed to members and interested persons in the early months of 1988. The Program Committee hopes that the diagnostic emphasis of contributed

papers will be balanced to represent all areas of interest.

Question: What about any new ideas or innovations for the program?

Answer: Although much of the planning is still in the early stages and many statements must be tentative, there is one innovation that will take place at the 1988 meeting that should be of interest to many. A special session, hopefully, will be scheduled that will be a take-off of "Places that Listen" in Curt's Organ. This session will be devoted to diagnosis of one condition which the audience will be challenged to "name that lesion".

Question: Sounds great! How will this part of the program be organized?

Answer: The Program Committee, under my direction, is in the process of inviting some of the top diagnostic audiologists across the country to present some most intriguing cases. The presentations will be staged in such a manner that the audience can interact and make a preliminary "guess" as what the final diagnosis may be for each case. We plan to have a wide variety of cases, including both adults and children, that are of primary diagnostic significance.

Question: What prompted you to come up with such an innovative session?

Answer: The purpose of having this special session was felt that it is highly relevant to all of us involved with clinical assessment. As clinicians, we are often faced with difficult cases. This will provide some good interaction between the "expert" and the audience. Since most clinical practitioners are interested in case studies, we are highlighting this in a way that should be fun as well as very educational. I will moderate this special session, and I hope to have some lively interaction among all participants.

Well, Frank, you and your Committee have certainly been hard at work already. I know I speak for all of us when I say I can't wait for 1988.

Jane Collins is named Outstanding Distinguished Teacher.

M. Jane Collins Granted Distinguished Teaching Award

The 1988 Annual Distinguished Teaching Award in Audiology was awarded during the American Audiology Society's annual meeting held in Chicago on September 21, 1987. This award was established by Bellini in 1981 and remains the only one in the field of audiology which recognizes the importance of teaching professionals to the continued growth of our field.

The Distinguished Teaching Award in Audiology is presented for teaching excellence, and, to be eligible, one must have at least five years' experience in teaching audiology and must be nominated by a student. Ten distinguished audiology researchers and educators from colleges and universities across the country are the judges for the award, joined by one member of the National Student Speech-Language-Hearing Association.

Eleven nominees were submitted for consideration this year. Needless to say, the judges faced a difficult task in making the final decision because of the superior quality of all individuals proposed. Each has fostered teaching excellence in a significant manner.

The 1987 Bellini Distinguished Teaching Award in Audiology was presented to M. Jane Collins, Ph.D., of Louisiana State University in Baton Rouge, Louisiana.

Dr. Collins is Associate Professor and Director of Audiology at her institution. In addition, she has adjunct status at the Kresge Hearing Research Laboratory of the South and in the Department of Otorhinolaryngology at LSU Medical Center in New Orleans.

Widely published herself, Dr. Collins is also an editorial consultant for the *Journal of Speech and Hearing Research* and for the *Journal of Speech and Hearing Disorders*. She has received numerous honors and awards for her research, and has, through her enthusiasm and willingness to involve her students, inspired a new generation of audiologists excited by original thought and discovery. Above all else, she asks

her students not to take for granted long-held assumptions.

A fellow clinical faculty member at LSU states that the 1987 award recipient encourages students "to question and evaluate for themselves even the classic evidence which supports 'truths' in audiology. Moreover, she does not simply provide information. [She] requires that students ask critical questions and work through problems themselves to arrive at conclusions.... She promotes and rewards creativity.... Her students have a high level of self-confidence, resourcefulness, and thoroughness in their clinical and research endeavors."

In all their comments about this year's recipient, Dr. Collins' colleagues and students point to her *emphasis on original thought* and her ability to bring out the best in each student, to capitalize on students' strengths while gently guiding them to fill in necessary holes, producing well-trained, confident graduates. In the words of the audiology department chairman at LSU, Raymond Daniloff, Dr. Collins has "the uncanny ability of fostering students' love of thinking without smothering their originality." He adds, "Only such a well published and enthusiastic researcher could be so fine a teacher."

It is certainly fitting that this award should have been presented at an AAS Annual Meeting, as the Society was the first professional association joined by Dr. Collins some 14 years ago.

Congratulations, Jane!!

19th International Congress of Audiology

The International Society of Audiology will hold its 19th International Congress of Audiology in Jerusalem, Israel, June 5-9, 1988. Topics of the round table (plenary) sessions will be Hearing Dysfunction Associated with Systemic Diseases, the Auditory Deprivation of Otitis Media, and Methods for Evaluating the Benefits of Hearing Aids.

Contributed papers at these congresses are accepted on a variety of topics in audiology, such as auditory physiology, psychoacoustics, auditory evoked responses, speech audiometry, central auditory tests, auditory disorders of aging, noise-induced hearing problems, hearing

aids, cochlear implants, auditory habilitation and rehabilitation, paediatric audiology, impedance measurements, epidemiology of deafness, high-frequency audiometry, middle ear implants, etc.

A one-day Pre-Congress Symposium on June 5, 1988, will consider the topic of Early Detection, Identification, and Management of Deaf Infants.

For further information contact:

19th INTERNATIONAL CONGRESS
OF AUDIOLOGY
JERUSALEM, ISRAEL, JUNE 5-9, 1988

Lucille Beck and Jerry Bunch receive editor's awards for outstanding article.

Deborah Hayes receives award for service as Section Editor.

Ear and Hearing Awards Announced

At the Chicago meeting of the American Auditory Society three awards were presented by the editor of *Ear and Hearing*. The first was an award to Deborah Hayes in appreciation for her service as Section Editor during the years 1983 to 1987. Deborah was editor of the Speech Audiometry section during that time.

A second special award was given to Frank E. Musiek for his tutorial series on neuroanatomy, neurophysiology, and central auditory assessment that appeared in Volume 7, 1986. The three part series focused on the brainstem, the cerebrum, and the corpus callosum and efferent pathways.

Finally, the Editor's Award for the outstanding article, which appeared in Volume 7, 1986, was given to Jerry L. Punch and to Lucille B. Beck. Their article was entitled, "Relative Effects of Low-Frequency Amplification on Syllable Recognition and Speech Quality" (pp. 57-62). The purpose of the Editor's Award is to acknowledge manuscripts that exemplify the standard of quality that the *Ear and Hearing* Editorial Board strives to achieve. The scientific standards to which the Journal subscribes and the basis on which manuscripts are evaluated include:

An interesting and well thought out research question.
Appropriateness of research design and methodology used in gathering data.
Appropriate analysis.
Clarity of writing.
Timeliness of the subject.
Appropriateness to purpose of the Journal.

The recipients of these awards are to be congratulated for their contributions to *Ear and Hearing*.

Frank Musiek is given special award for his tutorial series.

New Subjects Editor Joins Corti's Staff

Karen Patterson of Arkansas State University has joined the *Corti's Organ* Editorial Board as Clinical/Rehabilitative Audiology Subjects Editor. Karen holds her master's degree from North Texas State University and is currently completing her doctorate from the same institution. She holds dual certification in Speech-Language Pathology and Audiology. Karen is now an instructor in Communication Disorders at Arkansas State University in Jonesboro, Arkansas.

Karen brings to the *Corti's* Editorial Board a wealth of experience and extensive background in clinical and rehabilitative audiology. She is a member of Arkansas' Governor's Task Force on Deafness and Aging and is a member of the March of Dimes Executive Board. She has published numerous articles in the area of geriatric aural rehabilitation.

As Subjects Editor for Clinical/Rehabilitative Audiology, Karen will be responsible for articles and columns related to case studies, clinical practices, intervention programs, and other areas relevant to this segment of our profession. She will take charge of *Corti's* Aural Rehabilitation Forum. Karen has already begun designing some new and creative formats to be included in future issues. So, be prepared. She may be calling on you for input. If you have any ideas, articles, etc., for consideration in Karen's edi-

Karen Patterson

torial realm, you may contact her directly:

Karen Patterson

Telephone: (501) 972-3061
Welcome aboard, Karen!

Society Displays Debuts at AAO Annual Meeting

At the 1987 American Academy of Otolaryngology annual convention, in conjunction with the Society's annual meeting, a new concept for AAS was introduced. A portable display is now available for meetings, workshops, etc. The display describes the Society's organization and Executive Committee makeup. In addition, it depicts a sample of our activities, including our sponsored publications.

For many years now, members have shown an interest in "spreading the word" on the advantages of membership in the American Auditory Society. Last year, the Executive Committee agreed that the development of such a display would be an excellent way to communicate to both members and non-members what purpose our organization serves and what benefits can come from membership.

The display is quite portable and is an outstanding mechanism for promoting the Society. It would be useful for display at any activity where participants might share an interest in AAS goals and directions. For information on

obtaining the display for exhibit, contact Ross Roeser at 1966 Inwood Road, Dallas, Texas 75235.

Gerber Awarded Fulbright Grant

Sanford E. Gerber, University of California, Santa Barbara has been awarded a Fulbright grant to conduct research in England, the Board of Foreign Scholarships and the United States Information Agency (USIA) announced recently.

Dr. Gerber is Professor of Speech and Hearing Sciences at the University of California at Santa Barbara. He received his doctorate at the University of Southern California in 1962 and joined the UCSB faculty in 1965. He is a Fellow of the American Speech-Language-Hearing Association; a Fellow of the Society for Ear, Nose and Throat Advances in Children; and an Associate Fellow of the American Academy of Otolaryngology — Head and Neck Surgery. In addition, Dr. Gerber is an honorary member of the Czechoslovak Medical Society, and is also a member of the executive committee of the International Society of Audiology. Closer to home, he is a member of the boards of both the Santa Barbara and the California Associations for Retarded Citizens. He is the author of 10 books and scores of scientific articles dealing with handicapped infants. His work with the Medical Research Council of the UK has been to assess their programs for early identification of and intervention for at-risk infants.

Dr. Gerber is one of approximately 2,500 U.S. grantees being sent abroad for the 1987-88 academic year under the Fulbright exchange program. Established in 1946 under Congressional legislation introduced by former Sen. J. William Fulbright of Arkansas, the program is designed "to increase mutual understanding

between the people of the United States and the people of other countries." Approximately 7,000 grants are awarded each year to the U.S. students, teachers, and scholars to study, teach, and conduct research abroad, and to foreign nationals to engage in similar activities in the United States. Individuals are selected on the basis of academic and professional qualifications plus their ability and willingness to share ideas and experiences with people of diverse cultures.

More than 155,000 "Fulbrighters," over 54,000 from the U.S. and 101,000 from abroad, have participated in the program since it began 40 years ago. The program is administered by the U.S. Information Agency under policy guidelines established by the presidentially appointed Board of Foreign Scholarships and in cooperation with a number of private organizations. Scholarships are awarded through open competition, with final selections made by the Board of Foreign Scholarships. Twenty-seven foreign governments share in the funding of these exchanges.

The U.S. Information Agency is an independent agency within the executive branch whose mission is to inform other nations about American society and to provide opportunities for Americans to learn about the rest of the world.

For further information about the Fulbright Exchange program, contact:

Office of Public Liaison
301 4th Street, S.W.
Washington, D.C. 20547
Telephone: (202) 485-2355

Executive Committee member Don Worthington named "Arkansas Traveler" by Governor at State Association Meeting.

Activair/Duracell Funds Family Physician Program

As part of a coordinated effort by both the Better Hearing Institute and the Hearing Industries Association to inform nerve deafness patients and their family physicians about the benefits of modern hearing instruments, a pilot program has been made possible by a special grant from Duracell U.S.A., a division of Duracell Inc.

Duracell has sponsored a new edition of BHI's *Nerve Deafness and You* booklet, written by Gale Gardner, M.D., which emphasizes that hearing aids may be the most effective remedy for nerve deafness patients with some residual hearing. This counters the misconception revealed in BHI focus group studies and in the HIA marketing survey that people with nerve deafness cannot be helped.

Duracell is also funding a test mailing of the booklet to family physicians offering complimentary booklets for the doctor's patients or waiting room. This mailing will include a cover letter from James G. Jones, M.D., professor and chairman of the Department of Family Medicine at E. Carolina University, who is also personally fitted with binaural hearing instruments. A

follow-up survey will help gauge the project's impact for other possible mailings.

Reinforcing the Duracell-sponsored program are other BHI projects that include:

- * A new magazine public service advertisement featuring Arnold Palmer, released to major consumer magazines that have contributed millions of dollars worth of space to previous BHI messages. It complements a television public service announcement starring Palmer, currently being broadcast by local stations throughout the country.
- * A newspaper article, also written by Dr. Gale Gardner, emphasizing his nerve deafness booklet theme, issued to 4,000 daily and weekly newspapers across the United States.
- * A special BHI exhibit, dramatizing the nerve deafness help theme, which premiered at the "Time of Your Life Expo" attended by more than 42,000 senior citizens in Los Angeles.

Dr. Gardner, associate chairman of BHI's advisory board, is a member of the board of directors of the American Academy of Otolaryngology — Head and Neck Surgery.

Minutes of Editorial Board *Ear and Hearing*

Chicago, Illinois — September 20, 1987

The Editorial Board met at the Inn of Chicago. Those present included Irvin Gerling, Lucille Beck, Jerry Northern, Gail Neely, Susan Jerger, Laszlo Stein, Hiroshi Shimizu

1. The following announcements were made:

Kathy Grauvogel, who has been the managing assistant of *Ear and Hearing*, has been replaced by Marie Christakos.

Irvin Gerling who has been Editorial Assistant of the Journal was named Associate Editor.

2. Our manuscript flow is as follows:

We have received 85 articles to this date. That includes manuscripts published in the supplements. One year ago in November we had received 100 manuscripts. We are scheduled into February of 1988 with two manuscripts scheduled for April. There are presently 16 manuscripts in the review process; 18 are in the hands of the authors in revision.

The average time lapse between receipt of manuscript and the first editorial decision is 3.2 months, with a range from .5 to 9 months. The average time from receipt of manuscript to acceptance is 5.2 months, with a range over the past year from .5 to 21 months. The average delay between receipt of a manuscript and publication is 10.9 months, with a range of 5 to 25 months. The occasional long delay between receipt and acceptance for publication is due to sending a manuscript back to an author for revision.

3. The Editor's Award for most outstanding article appeared in Volume 7 and was written by Jerry Punch and Lucille Beck. A special award was given to Frank Musiek for his three part tutorial on the neuroanatomy of the central auditory system. Deborah Hayes was given a plaque acknowledging her four years of contribution on the Editorial Board.

4. Several suggestions were made to improve the appearance of the Journal.

5. A suggestion was made that any paper accepted for presentation at the annual AAS meeting become the property of the Journal for possible publication in *Ear and Hearing* following editorial (peer) review. Following discussion it was decided that we would encourage presenters to publish their manuscripts in *Ear and Hearing*, but that we would not insist that their manuscripts become property of the Journal.

In addition, we would provide presenters with information to contributors at the time that their paper is accepted; we would assure them priority review, but we would require that the normal peer review process be done and that final publication would be a decision of the editor.

6. There was a discussion of future issues and plans for 1988. Included in the suggestions for future articles was one on "clinically oriented basic sciences" that could include articles on toxicology, the auditory system, animal models of noise induced hearing loss in Meniere's disease, effects of aminoglycosides, etc. Another suggested topic was auditory manifestations of otologic diseases. Another was acoustic emission and its clinical application. Magnetic Resonance Imaging of the auditory system was suggested as a tutorial. Other suggested topics were: noise suppression techniques and amplification, psychoacoustics of auditory pathology, and late cognitive evoked potentials. I would appreciate any additional suggestions from the Editorial Board or from the membership about these or other subjects.

7. In the February issue there will also be a revision of information to contributors and also revision of the description of the journal sections. In 1988 we will return to the APA style of referencing, with author/date in the text and the references listed alphabetically.

8. Finally, Ken Startt from Williams and Wilkins, publisher, reported on the status of the Journal. Our circulation is approximately 3,000 including 2,000 plus members. Circulation has increased approximately 10 percent per year. In 1987 we had 66 pages of ads, which was a record year. There have been no problems with production. During the current year there were approximately \$11,000 in royalties that came back to the Society. Next year it is predicted the Society will receive \$23,000 in royalties.

9. Following the Editorial Board meeting a summary report of this information was given to the Executive Committee and an even briefer report to the membership during the business meeting.

10. At the business meeting the awards were presented.

Respectfully submitted,
Robert W. Keith, Ph.D.
Editor-in-Chief

1987 AAS MEETING AVAILABLE ON VIDEOTAPE

The 1987 meeting of the American Auditory Society is now available on videotape.

The videotape includes the Carhart Memorial Lecture by Peter Dallos entitled:

NEUROBIOLOGY OF THE COCHLEA: HAIR CELLS AS RECEPTORS AND MOTORS

The videotape is available in VHS format only. To order, send the specified amount after checking one of the below:

_____ I am sending a T-120 blank videotape. Please duplicate the 1987 convention tape and return it to me. Cost = \$25.00.

_____ I am not sending a blank videotape. Please send me a copy of the convention tape. Cost = \$35.00.

Make check payable to the American Auditory Society.

Send order to: Michael F. Seidemann, Ph.D.
Jo Achim Eye, Ear, Nose and Throat Hospital
145 Elk Place
New Orleans, LA 70112

The videotape should be mailed to:

Please allow 4-6 weeks for delivery.

AUDITEC of St. Louis Alive and Still Growing

(An interview with Dr. William F. Carver,
President of AUDITEC)

Editors Note: We learned that AUDITEC of St. Louis is celebrating its 15th birthday this year. In just 15 years the company has grown into what is probably the largest supplier of recorded auditory tests in the English speaking world. We felt that our readers would be interested in finding out more about this company. To accomplish this, we recently interviewed Dr. William F. Carver, President, owner, and founder of AUDITEC of St. Louis.

Dr. Carver, what were the circumstances that made you decide to start a venture such as AUDITEC?

I had been thinking about the concept for some time, but I wasn't certain about how to put it all together. Early in 1971 my wife and I were invited to dinner by a new acquaintance, Robert Hille, and his spouse. Bob was an announcer for a local television station and also had a recording studio in the basement of his home. He asked me if I would be interested in seeing his studio and, of course, I was. On the way back upstairs, I suddenly realized that here lay the perfect opportunity to follow up on the idea which had been ruminating up there in my brain for some time. I told Bob about it and asked him if he would be interested. He was and we did!

You said that the idea had been in your head for some time, when did it first occur to you?

William F. Carver

Early in the 1960's when I was Manager of Audiological Services for Beltone Electronics Corporation, the idea came to me, I don't recall what triggered it. But it seemed to me that Beltone should supply tape recordings of auditory tests as an adjunct to their audiometer line, and I suggested the same to the marketing people. The idea bombed; I couldn't even generate a glimmer of interest. Thank goodness I was a lousy salesman!

Getting back to Auditec's beginnings, can you give us a brief description of how it went after that dinner?

Well, before the evening was over, Auditec had been formed. Our first recording session was the next week as I recall. We recorded W-1, W-22, NU-6, PBK-50, children's spondees, and connected discourse (cold running speech). My partner, Bob, was the voice (except for the female connected discourse, of course) and I ran the tape recorder. The recording process was relatively easy. Bob was a good announcer and, after understanding how audiologists present word lists, performed with professional ease. My biggest problem

(Continued on Page 3)

1986 Convention Will Be A Hit!!!

The 1986 annual AAS meeting will feature Dr. Joseph E. Hawkins as the Carhart speaker. The title of his presentation will be "Traces of Age in The Ear and The Eye."

A gala evening of entertainment in Detroit's famous Greektown is planned

for the Association Dinner on November 20, 1986. A traditional Greek dinner followed by Greek folk entertainment will be the highlight of the evening. Dancing to popular music will be available after the entertainment to top off your evening!

1986 Call For Papers

William F. Rintelmann

The 13th annual meeting of the American Auditory Society will be held in Detroit, Michigan on Thursday, November 20, 1986. This year the meeting is scheduled immediately prior to the annual convention of the American Speech-Language-Hearing Association.

The program will consist of contributed papers placed in groups according to topic. The time allotted for each presentation will be 12 minutes.

Interested persons are invited to submit five copies of a summary approximately 300 words in length.

Authors' summaries of accepted papers will be printed in *Corti's Organ*. The deadline for submission is May 15, 1986. Notification regarding Program Committee decisions will be mailed to presenters by August 10, 1986.

Summaries must be postmarked by the submission deadline and should be mailed to: William F. Rintelmann, Ph.D., Chair, AAS Program Committee, Department of Audiology, Wayne State University School of Medicine, 4201 St. Antoine, Detroit, Michigan 48201.

Aural Rehabilitation Forum

Editor's Note: An area each of us as professionals needs to address is that of rehabilitation and intervention. Too often we are caught up in innovative diagnostic techniques and technology research, forgetting that we are service providers. Without attention to patient rehabilitation, we are limiting the focus of our service.

Because of this rehabilitation need, a new feature is being tried for *Corti's Organ*, the "Aural Rehabilitation Forum." Over the next few issues, a series of presentations and panel discussions will be included which were organized under the direction of Ronald L. Schow. The general theme of these articles will be aural rehabilitation concerns for aging adults. These discussions were presented as a part of a conference on aural rehabilitation held in 1983 at Winter Park, Colorado.

Each of these upcoming articles will thoroughly investigate one area of intervention services. But, there are many other populations that also need our attention. As you read this continued series, think about your personal experiences with your specific caseload. In order for this Forum to continue, other papers must be generated by our readers. Intervention is an area that concerns all of us. Let me hear your biases and feelings on any area of rehabilitation. Remember, we need to hear from pediatrics!

Rehabilitating the Elderly Hearing Impaired Audiologists as Hearing Aid Dispensers

Ronald L. Schow
Idaho State University
(First in a series of three.)

Abstract

This presentation summarizes the status of aural rehabilitation efforts for the elderly hearing impaired and calls attention to the great number who need but are not using hearing aids. Data are summarized which emphasize the importance of the hearing aid in rehabilitation. Efforts to improve the hearing aid and its delivery system are described, and a strong plea is made for a more united effort on the part of rehabilitation audiologists and hearing aid specialists, who have the same goal of helping the hearing-impaired elderly. Possible methods for more vigorous promotion and the ethical problems involved are discussed.

Some have wondered why a presentation on rehabilitative services for aging adults would want to concern itself with an issue like the dispensing of hearing aids. Perhaps it would be advisable to provide a rationale for this emphasis as I begin.

First, I should like to underscore the importance of amplification as the major rehabilitative tool in dealing with hearing loss. For some reason there is a persistent and, I think, mistaken notion that rehabilitative audiology primarily involves speechreading and auditory training. This general impression has been difficult to dislodge. Upon reflection most audiologists would concede that amplification really is part of the rehabilitation process, but somehow it is often perceived as being a separate matter. As a case in point, ASHA audiology convention committees include one on diagnosis, one on aural rehabilitation, and a separate committee for hearing aids.

Notwithstanding this tendency to separate amplification from aural rehabilitation efforts, I think that most of us recognize the importance of amplification in rehabilitation. It is, without dispute, the remedy used by more hearing-impaired persons than any other. Further, there are more audiologists by far involved in hearing aid evaluations and hearing aid follow-up than are involved in speechreading and auditory training therapy. Table 1 contains some 1980 data from a large representative sample of ASHA audiologists which demonstrate this (Whitcomb, 1982).

Table 1. Aural Rehabilitation Activities of ASHA Audiologists*
(N = 371 Total Respondents - 51% Return Rate)

	Number	%
Hearing Aid Evaluations/Fitting	295	80%
Hearing Aid Follow-Up/Orientation	308	83%
Counseling/Coordination with Other Professionals	304	82%
Speechreading/Auditory Training Therapy	148	40%

*Whitcomb, 1982

Without too much fear of contradiction, then, my first major premise is this:

1.) Amplification holds a place of pre-eminence in Aural Rehabilitation.

The second major point has to do with the importance of amplification for the elderly hearing impaired. I would argue that the elderly are not very different from any other segment of the hearing-impaired population in their heavy reliance on amplification as a solution for their hearing problems. The evidence indicates, as seen in Table 2, that about one-half of the hearing impaired persons in this country are in the retirement years (Schein and Delk, 1974).

(Continued on Page 5)

From The Editor

Now that the first two issues of *Corti's* for 1986 are under my belt, I am beginning to relax a little. As I'm sure it's obvious, our format has changed. I hope as readers you feel the "new look" is a move in a positive direction.

Beginning with this issue, other new dimensions have been added to *Corti's Organ*. I feel strongly that this publication should be more than simply a mechanism for distributing workshop information, directory details or miscellaneous news items. *Corti's Organ* should be our opportunity as professionals to publish papers, research, etc. in a relaxed, non-journal style manner.

In order to generate papers in various clinical areas, a new approach has been developed. Subjects Editors have been selected who will be responsible for articles on specific topics. All of us on the Editorial Staff hope that the preliminary areas chosen for attention are of interest to you as readers. At this time, two areas have been selected. We realize that these only begin to represent the different directions we take as professionals. We would like to expand our "coverage" of subjects but we can't do it alone. Do you have any area you'd like to "take charge of?" If so, please let me know.

Corti's is your publication. Without your input and assistance, it becomes a publication of a select few.

If you have papers, pertinent information, etc., that you wish to submit, please send it to one of the Editorial Board members listed below. Remember, there's room for your name.

1986 *Corti's Organ* Editorial Board:

Virgina Berry, Editor, 11701 St. Charles Blvd., Little Rock, AR 72211; (501) 371-2554 (office) and (501) 224-7833 (home).

Susanne Kos, Co-Editor (Advertisement), 1000 N. Davis, Suite D, Arlington, TX 76012, (817) 277-7039 (office).

Frank Brister, Ph.D. (Materials and Equipment Editor) Communication Disorders Center, East Texas University, Commerce, TX 75428, (214) 886-5910 (office).

William Domico, Ph.D (Clinical Editor), Memphis Speech and Hearing Center, Memphis State University, 807 Jefferson, Memphis, TN 38105 (901) 525-2682 (office).

To The Editor

I am currently researching data that I have gathered relating to hearing loss due to barotrauma. In my experiences with people flying, scuba and free diving, I have audiological information on hearing loss due to barotrauma.

I would like to use *Corti's Organ* and/or *Ear and Hearing* as a means of aiding my research. Should other hearing professionals have similar data, I would appreciate hearing from them. My data is limited to approximately twenty cases, and more case studies would be helpful.

Any assistance you could give me in this matter would be appreciated. Anyone having information to share, write or call: Peter Proul, M.A., Box # 10233, St. Thomas, US, Virgin Islands 00801, (809) 776-3546.

Members of AAS who attended last year's meeting will recall my introduction of SHARE, the Speech and Hearing Alliance for Resource Exchange, and the description that followed in *Corti's Organ* (Vol 10, No. 3, Fall/Winter 1985-86, P. 3). At the AAS meeting I handed out a description of the program. A copy is published on page 4. I

wanted to bring your readers up to date on the status of the program.

Since October I have been working to get additional support to acquire and distribute appropriate materials. With the help of Kristine Takekawa, past president of the National Student Speech/Language/Hearing Association and the organization's consultant, Dr. John Bernthal, we have received an endorsement by NSSLHA. That means we can contact the individual association chapters in order to solicit their support. In addition, NSSLHA is considering the possibility of adopting SHARE as one of their special projects next year. The support of NSSLHA is a significant step in the development of this program, and it is deeply appreciated.

I have received many phone calls and messages about SHARE, and have received several boxes of books and journals from individuals. Materials have already been forwarded to a graduate training program and also to a hospital-based cleft palate program in Sao Paulo, Brazil. We are corresponding with an otolaryngologist in Nigeria about some needed books there. In addition, there is a request from an investigator in Prague, Czechoslovakia, for some specific needs. They are looking for any of the three books authored in the early 1970's by Samuel Kirk and his co-authors on the ITPA. They include: Kirk, S.A., *The Diagnosis and Remediation of Psycholinguistic Disabilities*, 1966; Kirk, S., McCarthy, J., and Kirk, W., *The Illinois Test of Psycholinguistic Abilities*, 1968; and Kirk, S. and Kirk, W., *Psycholinguistic Learning Disabilities: Diagnosis and Remediation*, 1971. Perhaps readers of *Corti's Organ* could ask their speech/language colleagues if they have any books by Kirk that they would be willing to donate.

At this time we are attempting to identify individuals and training programs in countries where resources and finances are limited. To assist in this effort, a group of professionals, including Jon Shallop, Jerry Northern, Jose Barajas (Spain), Salah Soliman (Egypt), and Orozimbo Costa (Brazil), have agreed to serve as consultants. We are also interested in identifying any foundations that might provide financial assistance toward the cost of shipping materials. Any suggestions from readers of *Corti's Organ* would be welcome.

Our progress will be slow but sure. However, we know that we are on the right track and that efforts like this will serve the communicatively handicapped around the world. If you have books or journals to donate, let me know. I'd prefer a letter or call before you send them so that I can determine whether they are needed. Any cash donations that can be used for shipping costs will be equally welcome. Thanks for your help.

Any donations of resources or letters of inquiry should be addressed to:

Reflex Decay in Two Patients with Labyrinthitis

(The following is excerpted from a presentation by Kathleen D. Eccard, M.S., Suburban Hospital, Bethesda, Maryland, at the November, 1985 meeting of the American Speech/Language/Hearing Association.)

Labyrinthitis refers to inflammation of the labyrinth of the inner ear. Symptoms can include tinnitus, vertigo, hearing loss, or any combination of these. These complaints are often sudden in onset, and patients are usually treated symptomatically (1).

Adour, et al. (2) studied patients with acute vestibular neuronitis, acute labyrinthitis, and acute epidemic vertigo to test the hypothesis that vestibular vertigo is a manifestation of a viral cranial polyneuritis. Their patients demonstrated normal or bilaterally symmetric puretone audiometric results with abnormal electronystagmography (ENG), i.e., unilateral weakness of caloric response, or spontaneous or positional nystagmus. However, many of these patients also demonstrated transient cranial nerve dysfunction. On retest one month after the onset

of the symptoms, all but one of the sixteen patients had complete resolution of their signs and symptoms.

Two patients referred to the Neurotology Unit of Suburban Hospital with a diagnosis of labyrinthitis showed disappearance of acoustic reflex decay upon resolution of their presenting symptoms. These cases are discussed below.

Patient 1

M.C., age 37, was referred to this hospital by an otolaryngologist. Her symptoms included bilateral tinnitus ("extra loud when dizzy"), and true vertigo. She reported no decrease in hearing and no significant personal or familial history of auditory or vestibular disorders.

The hearing evaluation indicated normal hearing bilaterally, with 100% speech discrimination in each ear using the W-6 word list. No PI-PB rollover was obtained in either ear. Immittance testing indicated normal middle ear pressure and compliance bilaterally. Acoustic reflex thresholds were within normal limits bilaterally when stimulated ipsilaterally and contralaterally.

(Continued on Page 3)

AUDITEC (Continued from Page 1)

was getting him (and the female voice too) to read the connected discourse *without* inflection! The most time consuming task was editing and reordering the words for the different "forms." It was several months before we were ready to sell our tapes.

Who else was involved with Auditec?

No one. It was just Bob and I.

You were working for Washington University Medical School then, weren't you? Did you quit then?

Oh no, both of us kept our regular jobs. No, we just worked one evening a week. And I spent extra time weekends on the business end, and shipping, invoicing, etc.

How did you market your tapes?

Word of mouth. Since both of us had full time jobs, we just kind of eased into the market place. Backed into it might be a better description. I told a local distributor of audiometers (and a friend as well) about our venture and he began to distribute the tapes and also to pass the word. After a time, I thought we should advertise, but Bob didn't want to. Nevertheless, the word spread, slowly, and business increased a little each year. I found that I was spending more and more of my weekends doing Auditec business, though we still only needed to record once a week.

Your product line is considerably larger than you described earlier. How did that happen?

I contacted audiologists who had developed tests, (one contacted me) with the proposal that Auditec market their tapes for them. We obtained three new tests that way. Having these tests in our catalog helped us expand because persons would read about the test in a journal, ask the developer for his test, and he would refer them to us. This gave us the opportunity to tell them of the rest of our line.

I know that you have a lot more tests than that. What happened next?

I believed that Auditec could grow into a company which would supply most of the recorded needs of the audiologist. But I also knew that to accomplish this, more time and effort would have to be devoted to the business than we were giving it then. At that time Auditec could not support one of us, much less both of us, but I knew that the potential was there for at least a one man operation. So, in 1977, I borrowed a pile of money, bought out my partner, left Washington University, leased a space for the studio, and took a part-time teaching position to help support me while I tried to make Auditec self

supporting. To make it work, for four years I spent seven days and evenings a week either teaching or working on Auditec business. I think my family forgot what I looked like, but I made it work.

Did you do anything special to make Auditec grow?

Simply put, I began to let people know that Auditec existed. I advertised and used direct mail on a limited basis (not too much money to work with then). I began to expand the product line with materials which I thought audiologists might want. Also, test developers continued to contact me allowing further expansion of the line. My hunch about Auditec's potential was right, my gross sales increased 55% the first year post-partner and 40% the next year!

Wow! That's quite a record. Have you been able to maintain that pace?

Don't I wish! No, growth has been sort of up and down, more or less following the nation's economy. 1985 was a banner year, though, and I look forward to an even better year in 1986.

How big is your product line now and how can our readers get information on it?

Our catalog lists 69 reel-to-reel items, 85 cassette items, two video tapes and a variety of supporting printed materials. The catalog is available to anyone who wants it, simply write or phone, we'll send one by return mail.

I would like to add that Auditec is still very small. I employ two part-time individuals now. That's it. But this allows us to be very flexible; we act like a "job-shop." That is, we can record to order almost anything that one may desire.

Let's change the subject to the technical end of the recording business. What are some of the technical problems that one faces in recording speech testing materials?

Our biggest problem is "print-through."

Print-through, what's that?

When one section of recorded tape lies next to another section of tape as they do when stored on reels or cassettes, the magnetized (recorded) particles in that section will partially magnetize the adjacent sections, both above and below. On tape which has continuous material recorded on it such as music, or our cold running speech, the print-through is so minimal that it escapes detection most of the time. With our tapes, however, the majority of the tape is blank. There are at least four seconds of silence between stimuli on our standard tapes, but stimulus duration is just over a second in most cases. Therefore, the stimulus material is highly likely to lie next to virgin tape, inducing its signal on it, at a markedly reduced level, of course, but audible, especially when played at high output levels.

What can you do about it?

I'm afraid that it's not enough, especially for those individuals who employ very high output levels, looking for roll-over. We use "reproduce" tape which has good (reduced) print-through characteristics. We record at slightly reduced levels (relative to "standard record level"). Finally, we use an electronic gate between our master tapes and the production copy. The result is that the print-through is about 50 dB below the level of the primary signal, sufficient for most speech discrimination tasks. Recently a study was reported in **EAR AND HEARING** which used one of our tapes. In the appendix of their article they indicated that while print-through was audible, it was not discriminable, even at high levels.

Any other problems?

Yes, we need standardization. The industry has audiometer standards, but there is nothing for speech testing materials. Standards not only maintain or upgrade

(Continued on Page 6)

International Hearing Foundation

Week in Minnesota

This otology/audiology/technology "Week in Minnesota" will begin on June 2, 1986, with the Minnesota Ear Surgery Course. The Course will consist of a temporal bone dissection format, with workshop and discussions led by Drs. Potami, Sadé, Tos, Maniglia, Paparella, Goycoolea, Koutroupas, etc. It will be held at the Minnesota Head & Neck Center.

Friday, June 6, brings the Clinical Otology Workshop with a number of luminaries discussing such topics as "Sensorineural Hearing Loss in Children," "Anatomical Variations," surgical procedures, cochlear implant updates, etc. Additionally, Friday's workshop faculty will include Drs. Facer, Portmann, McGee, Shea, Hough, Schuknecht, and Mecklenburg.

The International Hearing Symposium being held on Saturday and Sunday, June 7 & 8, 1986, at the Amfac Hotel in Minneapolis offers an ecumenical meeting involving medicine, otology, technology, and business/marketing arenas. An international cast of speakers in medicine, professional and technological fields, including many of the above-named physicians, as well as Kurt Hecox, M.D., James Jerger, Ph.D., and Jerry Northern, Ph.D., will be participating in this outstanding symposium. This will be highlighted by the Reese Award and banquet being held on Saturday night at the Amfac.

The Reese Award is a new annual award for advancement in biomedical and technological hearing research. The recipient, chosen by an international scientific committee, will receive a \$30,000 cash award plus a gold medal. This presentation will be made at the banquet, which will also include an appearance by a special guest speaker.

Last, but certainly not least, is the Minnesota Audiology-Technology Symposium/Workshop to be held on Monday, June 9, as a continuation under the

(Continued on Page 10)

INTERNATIONAL HEARING SYMPOSIUM

June 7 and 8, 1986

Amfac Hotel

Minneapolis, Minnesota

This unique two day symposium combines Current Developments in Medicine, Audiology and Technology on such practical topics as medical and surgical treatment, audiology, hearing aids, technology, marketing, etc.

The first annual international award for hearing, the Reese Award, will be presented at the Award Banquet.

An outstanding faculty of international authorities includes Drs. Schuknecht, Maniglia, Jerger, Tos, Sadé, Northern, Hecox, Ward, McGee, Oliveira, Goldstein, Goycoolea, Paparella, Hough, Lim, etc., along with leaders of technology.

In addition, symposium attendees can participate in "bonus" sessions on June 9 dealing further with audiology, technology and marketing, as well as hands-on earmold and ITE modification experience.

For more information and registration (modest fee includes Award Banquet, lunch, etc.) please phone or write to:

International Hearing Foundation
701 25th Avenue South
Minneapolis, Minnesota 55454

New Officers of Acoustic Systems Named

Earnest Butler, Chairman of the Board of Acoustic Systems, formerly Tracoustics, Inc., announces the election of Jeff G. Schmitt as President. Mr. Schmitt joined the company as an intern while in graduate studies at the University of Texas. He holds a BSEE and a Masters degree in acoustics.

Bill Weitzenkorn, Wyndy Ellis and Steve Hart were also appointed as Corporate Officers at the annual shareholders' meeting. The Austin based manufacturer designs and constructs audiometric examination rooms and suites as well as systems for industrial noise control.

Aural

(Continued from Page 1)

Table 2. Percentage of Significant Bilateral Hearing By Age*

Age In Years	Percent of Total Population
Under 6	0.8
6 - 16	5.9
17 - 24	3.6
25 - 44	9.8
45 - 64	28.6
65 - and over	51.3
	100.0

*Schein and Delk, 1974

Other evidence in Table 3 indicates that about one-half of the hearing aids being used in the U.S. are based by the elderly (Eisenberg, 1976; Cranmer, 1983).

Table 3. Percentage of Hearing Aid Purchasers by Age
Percent of Total Hearing Aid Sales

Age In Years	**1970-75	*1980	*1981	*1982	*1983
18 and Under		9.1	8.1	5.8	7.0
19-39		11.7	8.5	7.6	9.7
40-65		30.5	26.7	29.4	27.7
66 and Over	56.5	48.7	56.7	57.2	55.5

**Eisenberg, 1976
*Cranmer, 1983

This suggests that the elderly are more or less using their proportionate share of the hearing aids. My first point, then, may be modified to include the elderly.

2.) Amplification holds a place of pre-eminence in Aural Rehabilitation for the elderly hearing impaired.

The next issue has to do with the pathetically limited use of hearing aids by the hearing impaired, both old and young alike. Even the most conservative estimates of hearing loss indicate there are about 15-16 million Americans who have bilateral hearing losses of various degrees (Mahon, 1982; Punch, 1983). However, there are only about 2.5 million in this country using hearing aids (Mahon, 1982). That is no more than about 17% of the hearing-impaired population (See Table 4).

Table 4. Estimates of Hearing Impaired Persons and Hearing Aid Wearers in Various Countries

	U.S.*	Canada**	Scandinavia***
Hearing Impaired Persons	15,118,000	708,000	1,210,000
Hearing Aid Wearers	2,588,760	283,000	370,000
Unaided	12,529,240	425,000	840,000
% of H.I. Using Aids	17%	40%	31%

Sources: Hearing Aid Journal, November, 1981**, Mahon, 1982*, and Skadegard, 1982***)

In Canada and certain Scandinavian countries where hearing aids are supplied with government support, about 30-40% of hearing impaired persons use aids (Hearing Aid Journal, 1981; Skadegard, 1982). In the United States this means that about thirteen million hearing-impaired persons are not using aids, and about half of these are elderly persons. If we then ask what can we do as rehabilitative audiologists to help the several million elderly hearing impaired, one answer is that we should try to find out why about seven million of them are not using hearing aids. Further, we might ask "What can we do to get more of them to consider this solution?" Still another question is: "Will any of those not using aids be helped to communicate better by using one?" I think the answer to the last question is "yes". The higher use figures in Canada and the Scandinavian countries would suggest a higher percentage can be helped. In fact, these numbers suggest we should be able to at least double hearing aid use in this country.

Reasons For Non-Use of Hearing Aids

Are hearing aids not being used because of a faulty product, or because of a poor delivery system, or both, or could there be some other reason?

I suggest that there are problems in both aids and the delivery. Hearing aids have improved, and any number of special features have been devised so that these amplification units function better. Still there has not been a major breakthrough to an aid that most people simply put on and refuse to take off because it is so satisfying. Audiologists and manufacturers will continue to work for improvements, but if the magic breakthrough ever comes, it could certainly change the use of aids.

Assistive listening devices may help us overcome some of the product problems if we can get people to use them. While we are waiting for other technical developments, and learning to use the improvements available, what can we do to improve the hearing aid delivery system? If the government could be persuaded to give hearing aids away, that would certainly help. We probably cannot look to government agencies to give away more hearing aids. So what else can be done?

Dispensing Audiologists or Hearing Aid Dealers

Perhaps all hearing aids should be dispensed by audiologists. Would that create a major change in hearing aid use? Would elderly persons seek services from audiologists in large numbers? The evidence after about ten years of audiologists' dispensing is encouraging. For example, these data in Table 5 suggest that hearing aid users fit by dealers are less satisfied than users fit by audiologists (Oja & Schow, 1984).

(Continued on Page 5)

Speech and Hearing Alliance For Resource Exchange

Share

The primary purpose of SHARE is to assist in the international development of Audiology and Speech/Language Pathology training programs and services through the sharing of surplus textbooks, journals, reprints, or other materials and resources.

A secondary purpose is to share experiences and information among persons with a common interest in helping the communicatively impaired.

The primary recipients of these resources will be training or clinical programs in developing nations which do not have the means to purchase journals and textbooks necessary for the development of professionals, and which will serve the communicatively handicapped in their countries.

Books, journals, and other materials will be obtained through donations from individuals and libraries. Although more recent editions of textbooks are most useful, any edition can provide background information for beginning scholars or serve as a reference for more advanced professionals. In addition, all volumes of professional journals would serve as valuable resources.

The conduit for distributing these materials will be the Communicative Dis-

orders Foundation, a non-profit tax-exempt foundation. The president of this foundation is Donald A. Shumrick, M.D., and the vice president is Robert W. Keith, Ph.D. The Communicative Disorders Foundation has obtained a start-up donation to cover the expense of forwarding materials to recipients. Additional grants and donations will be solicited.

Tax deductible gifts of books, journals, materials, or cash will be acknowledged in writing by the Communication Disorders Foundation. The acknowledgment will contain an itemized listing of books, journals, or materials donated for distribution.

Suitable recipients will be forwarded materials appropriate to their needs. A stipulation of the exchange is that materials will be placed in libraries where they will be generally available to scholars.

Any donations of resources or letters of inquiry should be addressed to: Robert W. Keith, Ph.D.
Div. of Audiology and Speech Pathology
Dept. of Otolaryngology
Room 6009

Telephone: 513-872-4893

Reflex Decay

(Continued from Page 2)

ally. Acoustic reflex decay testing, performed at 10dB above the reflex threshold at 500Hz and 1000Hz (3), was normal in the left ear. Reflex decay testing in the right ear produced a positive retrocochlear sign, with decay of greater than 50% within 5 seconds at both 500Hz and 1000Hz on two consecutive trials.

ENG results indicated peripheral involvement with unilateral gaze nystagmus with eyes closed, positional nystagmus with eyes closed, and a non-localizing directional preponderance to the left.

Auditory Brainstem Response (ABR) Audiometry performed three months after the initial evaluation was normal. By this time, the patient reported complete resolution of the symptoms of vertigo and tinnitus. Reflex decay testing was repeated and was found to be normal in both ears.

Patient 2

M.G., age 49, presented with a three day history of "a feeling of water" in the right ear, tinnitus, and true vertigo. A diagnosis of labyrinthitis had been made by the referring otolaryngologist. An illness four years previously, also diagnosed as labyrinthitis, had resolved spontaneously.

Hearing tests done by the referring physician's audiologist were within normal limits bilaterally. Immittance test results indicated normal middle ear pressure and compliance bilaterally. Acoustic reflex thresholds were within normal limits, except for an absent reflex at 120dB SPL with ipsilateral stimulation in the right ear.

There was no acoustic reflex decay with the stimulus in the left ear. Questionably significant reflex decay was obtained on two consecutive trials with the stimulus in the right ear, i.e., greater than 50% within 5 seconds at 1000 Hz but less than 50% at 500Hz.

The ENG suggested peripheral involvement with spontaneous and/or positional nystagmus with eyes closed. Immittance measurements were repeated 23 days later. No reflex decay was obtained in either ear.

ABR tests, performed five days after the repeated immittance tests, were normal bilaterally. The patient reported significant diminution of the symptoms reported one month earlier.

In the Adour, et al. study (2), cranial nerves V (Trigeminal), VII (Facial), VIII (Acoustic), IX (Glossopharyngeal) and X (Vagus), as well as the second cervical nerve, were reported to be involved in acute vestibular vertigo. Their patients had acute vertigo with vestibular manifestations and no cochlear involvement, abnormal electronystagmographic (ENG) findings, and a normal neurologic examination. No mention was made of acoustic reflex measurements and/or reflex decay testing in the Adour study.

The findings reported here indicate that labyrinthitis can possibly affect the acoustic reflex, producing decay. These results may appear to support Adour's hypothesis of a polyneuritis involvement in acute labyrinthitis. Further investigation in a more controlled manner, with a larger population, could determine whether a true association exists between labyrinthitis and acoustic reflex delay. Such a study could also help determine the sites of involvement in labyrinthitis.

Table 5. Summary of Hearing Aid Satisfaction Results on Sample of 45 Hearing Aid Users*

Dispenser	N	%	Highly/Moderately or Slightly Satisfied	Neutral or Slightly/Moderately/Highly Dissatisfied
Audiologist	19	42	89%	11%
Dealer	26	58	50%	50%

*(Oja & Schow, 1984)

This is certainly not the last word on the subject. Unfortunately, other data are very limited comparing the work of hearing aid dealers and audiologists. Whatever those data may ultimately show, if and when we get them, we do know this: Hearing aid users are not deserting the dealers in droves, nor are all audiologists providing 100% satisfaction on all fittings.

Statistics drawn from our 1980 survey indicate that about one of every five audiologists was at that time involved in dispensing hearing aids (Whitcomb, 1982). What impact are audiologists having as hearing aid dispensers? Are we doing a better

International Congress Scheduled

The International Congress on Brainstem Auditory Evoked Potentials is being held October 20 - 22, 1986, at the Summit Hotel, New York N.Y. It is sponsored by Brooklyn College, City University of New York, and co-sponsored by the School of Medicine, University of Pittsburgh, and Guinta Associates, Inc. The Congress will address the state-of-the-art of brainstem auditory evoked potentials and will isolate and critically evaluate central scientific and clinical problem areas. Not a "how to" workshop, the Congress will include critical reviews and presentations by internationally renowned scientists and clinicians. The topic is addressed with a focus toward specifying key problem areas leading toward recommendations for future research and clinical applications. In addition, the first day will be devoted to invited papers and selected submitted reports. The Congress proceedings will be published.

The Organizing Committee Chairperson is Aage R. Moller, M.D., Ph.D. The Congress Director is Shlomo Silman, Ph.D. The Organizing Committee members include Keith H. Chiappa, M.D., J.J. Eggermont, M.D., Stanley A. Gelfand, Ph.D., Aage R. Moller, Ph.D., Frank E. Musiek, Ph.D., Michael Seitz, Ph.D., Shlomo Silman, Ph.D., Arnold Starr, M.D., James J. Stockard, M.D. The Operations Chairperson is Carol A. Silverman, Ph.D.

In addition to the organizing committee members, featured speakers include Dr. Clarke Cox, Dr. Manuel Don, Dr. Robert Galambos, Dr. Michael Gorga, Dr. John T. Jacobson, Dr. James Jerger, Dr. Paul Kileny, Dr. David R. Stapells, Dr. Terence W. Picton, Dr. Hillel Pratt, Dr. Daniel

Schwartz, Dr. Laszlo Stein and others.

There is a Call for Papers on BAEPs. The deadline for submission of papers (Abstract of up to 200 words and a Summary of up to 800 words containing the introduction, method, results, and discussion) is June 30, 1986. The registration fees are as follows: Physicians, \$325 (\$350 for late registration); Audiologists, Residents, and other Professionals, \$265 (\$290 for late registration); and Students, \$155 (\$180 for late registration). The deadline for payment of registration fees is September 2, 1986. The registration fees include attendance at the Congress and lunch on the first and second days. There is a \$6.00 fee for ASHA Continuing Education Units (2.3 CEUs).

Brooklyn College is approved by the Continuing Education Board of American Speech-Language-Hearing Association to sponsor continuing education activities in speech-language pathology and audiology. As an organization accredited for Continuing Medical Education the Accreditation Council for Continuing Medical Education, the School of Medicine, University of Pittsburgh, designates this continuing education activity for 22.5 credit hours in Category 1 of the Physician's Recognition Award of the American Medical Association.

For further information call Dr. Shlomo Silman, (718) 780-5186 or Dr. Carol A. Silverman (212) 517-0576. Checks are payable to Brooklyn College and papers and registration fees should be mailed to: Shlomo Silman, Ph.D., Speech and Hearing Center, Boylan Hall, Brooklyn College, CUNY, Bedford Avenue and Avenue H, Brooklyn, New York 11210.

job than hearing aid dealers? Perhaps, but we have to qualify that answer pretty carefully.

I think there can be little argument but that audiologists, as a group, understand the technical aspects of hearing aid fitting better than dealers, or specialists as some prefer to call them. How important are these technical details in fitting? A dispensing audiologist friend of mine estimates technical aspects amount to 5% of a total quality dispensing process. He says the major thing needed in dispensing is good counseling, which includes full hearing aid orientation among other things, and which helps the client develop realistic expectations for the aid. Are the audiologists any better at counseling and orientation than the dealers? Naturally, it depends on the individuals involved. Audiologists, however, generally have more formal training in counseling and orientation. They have another advantage as well. They are trained to focus on the communication handicap and not on the "sale". This attitude toward the sale is often a major difference between dealers and what audiologists ought to be. I know two audiologists who have tried to work with dealers... good dealers, mind you, and finally in both cases, this sales attitude was the fundamental difference which broke up the arrangement.

The public confidence in the hearing aid dispenser is a very subtle and an important dimension in fitting aids. Audiologists have a natural advantage here because of our training and credentials, but it has to be more than "window dressing". It has to be reflected in a "genuine professionalism". We have to know what really matters most. I would submit that some of us, who are not in dispensing and extensive follow-up activities, may have a hard time finding out what really matters most with amplification. As a case in point I will tell you about a recent experience of mine.

After being an "ivory tower audiologist" for ten years, (meaning I have been doing hearing aid evaluations but not dispensing), I have recently had the opportunity to work with my mother as she has been fit by a local dispensing audiologist. Frankly, I have been amazed by the matters that seem to be of most concern to her. Gain, frequency response, and output limiting devices have been very, very peripheral, almost unimportant matters in her fitting. Much, much more important has been whether to buy an in-the-ear or a behind the ear unit. That decision ultimately was resolved to my satisfaction with the style that I believe has a better chance of being properly fit on her loss. But for what reasons?? Partly, it was my professional advice and that of my dispensing colleague that the behind-the-ear unit would give a better chance for an acoustically good fit. Far more important for her personally, however, were the following facts:

1. Her manual dexterity is good enough that she can manipulate the behind the ear unit without difficulty.
2. In her estimation it is less noticeable than the in-the-ear unit.
3. The particular behind-the-ear units in question have a two year warranty while the in-the-ears have only a one year.
4. The behind-the-ear units have a very low current drain, thus allowing for long battery life.

Electone has numbers that mean something

23 years of providing quality hearing aids at the lowest prices with the best service.

33 years of personal experience as a dispenser and manufacturer of hearing aids. Call Manny Gittles, President. He will be glad to talk to you.

12 different custom ITE models to choose from.

32 different frequency response options to choose from.

15 BTE models at low prices that will surprise you.

35,000 sq. ft. new manufacturing facility designed specifically for the manufacture of custom ITE's and BTE hearing aids.

5 day turnaround on ITE hearing aids.

These numbers add up to a total that you can not afford to over look.

quality, but give us guide lines so that everyone knows what to expect from a recording. Presently we record to "accepted practice."

And what is accepted practice?

Candidly, at Auditec it's what I think ought to be! OK, it's not really that bad. During my post-doctoral fellowship at Northwestern University under Tillman and Carhart, I learned how they prepared their tapes and, to a great degree, I follow their methods today. For instance, in most of our tapes, we zero the VU meter on the word *preceding* the stimulus word. The talker is trained to level at zero on "word" of the phrase "say the word..." and to let the stimulus word which follows fall naturally. This technique tends to insure that the stimulus word is not distorted by over (or under) emphasis in an attempt to reach zero VU unnaturally. One mistake that a lot of audiologists make when giving a test via live voice is to over-emphasize the stimulus word, especially the last phoneme, frequently almost making a two-syllable word out of it. The stimulus word should be spoken as if another word were going to follow immediately.

Do you have any advice on tape and tape recorder care?

Thank you for asking. I am aghast at the lack of care that people give their tapes and tape decks. The decks are mechanical devices which require periodic care. Tapes can be ruined by uncared-for decks. Tapes are treated as if they were completely

immune to destruction, or worse, to slow, unnoticed deterioration.

Can you give us some brief advice?

First, tape should be stored smooth wound, tail out...

Wait a minute, what do you mean, "smooth wound, tail out?"

At the end of the day, the tape should not be re-wound, but left played to the end or "tail-out." Fast rewind or fast forward will result in an uneven wind and unequal tension. The edges of the tape can be bent against the side of the reel. Regular wind speed, "play," will result in a smooth even load at equal tension, hence "smooth wound, tail out." Also, any print-through that occurs will follow the stimulus rather than precede it.

OK, what else?

Dirty heads and out-of-line heads will degrade the high frequency response of a tape. Recorded tape repeatedly passing over the tape heads will slowly build up residual magnetism. A magnetized head will permanently degrade the recorded material on a tape, again in the high frequencies.

Therefore, the tape heads, capstan and all other parts which come into contact with the tape should be cleaned periodically. Commercial cleaners are available from an electronics store. Simply follow the instructions on the bottle. Next, the

Equipment Review

Infrared Assistive Listening Devices

Submitted By Rod McLennen

Amplified speech presented in large room and outdoor environments may be distorted through echo, noise, reverberation, distance or spectral deformation. The transmission characteristics from the finest sound systems will create less than a perfect copy of the input signal, imposing on the listener some degree of intelligibility degradation. For those individuals with minimal hearing impairment and for those who seek assistance through hearing aids, the solution has not been readily available. In fact, these conditions provide for an environment of such frustration that many individuals choose to avoid activities involving large room acoustics.

Manufacturers have sought to rectify this situation, reducing negative environmental factors by delivering the speaker's message directly to the listener. Communicative enhancement has been obtained

through such systems as direct line, audio loop, AM and FM devices. Over the past several years, however, significant interest has been focused on large and small room infrared assistive listening device systems. The purpose of the present article is to summarize information in such broad categories as function, application, advantages, disadvantages, and manufacturers specification of the infrared assistive listening device.

Function: Infrared light is a carrier source for audio frequencies usually in the range of 40-15k Hz. However, the infrared receiver will restrict the bandwidth reaching the ear to approximately 50-8k Hz. This invisible carrier is low in energy with a wave length slightly shorter than visible light. The system contains the infrared emitter/transmitter with infrared receivers. Audio signals are coupled from a microphone or amplifier to the emitter/transmitter where light emitting diodes illuminate the designated field of reception. Guidelines exist for determining the size

(Continued on Page 8)

Aural (Continued from Page 5)

This last item is perhaps the biggest of all, and underscores the strange, non-technical factors that are so important in the fitting of aids and the satisfaction of the elderly. I am reluctantly becoming convinced that an audiologist can do more with effective counseling skills which focus on communication, and with a good dremel drill and a few filters, than I can if I focus only on my knowledge of comparative hearing aid procedures, prescription formulas, and speech audiometry. Maybe many audiologists don't know enough about what matters most. I shudder when I think how many are out there dictating to the dealer exactly which brand and model to fit, as our 1980 survey shows that 88% of them are doing (Whitcomb, 1982). Unless these audiologists are heavily involved in the follow-up process, this may be a gross abuse of power.

In short, I suspect that despite tremendous advances we still have a number of problems with both the product and the delivery system. I don't think audiologists have all the answers to the delivery problems either. In other words, doing away with all the dealers would not solve our delivery woes.

Now that we have learned firsthand that we can't instantly solve all the problems that the dealers and manufacturers have been struggling with for several decades, I suggest we should be more open to considering the efforts dealers are making to increase the use of hearing aids. Table 6 shows they are doing a lot more advertising than we are (Cranmer, 1983).

Table 6. Percentage Using Various Types of Promotion in Hearing Aid Sales*

	Dispensing Audiologists	Hearing Aid Specialists
Newspaper	43%	75%
Radio	4%	9%
TV	0%	8%
Direct Mail	33%	66%
Phone Directory	65%	63%

*(Cranmer, 1983)

I recommend that we, as rehabilitation audiologists, need to lend vigorous effort to the amplification area. We need to learn to use whatever we can — like assistive devices or perhaps advertising. But we must be careful that our efforts are motivated by a true professional attitude with emphasis on communication improvement, not sales. If not, we may end up lacking the professionalism we pride ourselves on having.

If audiologists were to turn to vigorous promotional techniques, like indirect mail and heavy advertising, which are time honored tools being used to promote many products, including hearing aids, could we fit and help more persons with hearing loss? Or would we only become unprofessional and lose some of the confidence we now enjoy with clients and the elderly? What would be the ethical and professional problems with using more vigorous advertising efforts in promoting hearing aid use? How does this relate to all ethical problems associated with dispensing? Our next presentation and panel discussion will focus on these issues.

Support Needed For Congressional Legislation

Various subcommittees in the House of Representatives are currently considering passage of a bill (H.R. 1403) which will guarantee continuing financial assistance to the aged and disabled who need audiological services and auditory rehabilitation. Funding for the bill has already been arranged through an excise tax on cigarettes.

Unfortunately, the bill is in danger of dying in the subcommittees listed below. Your help is needed to save this legislation. We strongly encourage you to write to committee chairmen and to committee members from your state, urging them to request a prompt hearing for the bill, to provide their support, and to sign the bill as a co-sponsor.

Engstrom Awarded the 1985 Amplifon Research & Studies Center Int'l Prize

On Friday, March 21, at 9 p.m., at the Milan Press Club, Swedish professor Hans Engstrom was awarded a prize of ten million lire by A. Charles Holland, president and founder of the Amplifon Research and Studies Center. Engstrom was granted the CRS award for having devised an investigation methodology using the electron microscope. This new methodology represents a powerful diagnostic tool in auditory pathology.

During the award ceremony, Tedo Madonia, Professor of Audiology at the University of Catania, presented Hans Engstrom and his works; introduced Ettore Pirodda, Head of the Otorhinolaryngology Clinic at the University of Bologna; and coordinated the round table discussion on the cochlear ultrastructural and physiopathological bases of sensorineural hearing disorders. Speakers were Massimo Del Bo, Head of the Institute of Audiology at the University of Milan; Salvatore Iurato, Head Professor of Bioacoustics at the University of Bari, and Paolo Menzio, Head of the Otorhinolaryngology Clinic at the University of Turin.

Who is Hans Engstrom?

Head of the Biomedical Center and Department of Otorhinolaryngology at the University of Uppsala since 1979, Hans Engstrom started his career in medicine at the Karolinska Institute in Stockholm. Here the more important steps in his career were taken.

This Swedish scientist, a prolific author, published, among other works, two important monographs and wrote many articles on clinical research and basic science. For his research work, he was granted international recognition and prizes in various countries, including the "Shambaugh Prize" in the United States and the "Swedish Medical Association Prize" in his own country.

As a member of this medical association he achieved significant results in collaboration with a team of American specialists. This cooperation often extended to cholera coming from other countries; it has produced important studies and innovative hypotheses to stimulate new research.

A member of the leading otorhinolaryngology societies throughout the world, Hans Engstrom often attends the most important meetings, presenting the results ob-

tained through his original studies using the electron microscope.

"Surface Preparation": The Electron Microscopy Research Method devised by Hans Engstrom

Professor Engstrom devised an innovative electron microscopic method of "surface preparation" for studying cochlear cells. These cells are normally seen wound spirally around the cochlea. Engstrom's procedure provides a method of unwinding the spiral and of spreading out the nervous cells as on a keyboard. Thus, his surface preparation allows numerical counting of healthy and diseased cell, and provides a basis for a more scientific understanding of the origins of auditory disorders.

The Amplifon Research and Studies Center International Prize

This recognition, which has now been bestowed fifteen times and is known as the "Nobel Prize for Audiology", is given by the Amplifon Research and Studies Center according to the votes of a commission representing the major national and international scientific societies in the field of otolaryngology and audiology.

This International Prize is part of a wider educational and research program covering both the organization of conventions and meetings, and extensive didactic and publishing activities.

In previous years, the Amplifon Prize was awarded to two scientists from Italy (Ettore Bocca and Michele Arslan), two from France (S. Borel Maissonny and Jean Marie Aran), two from West Germany (Horst L. Wullstein and Wolf D. Keidel), two from Sweden (Erik Wedemberg and Nils G. Henriksson), one from Israel (Heim Sohmer), one from Japan (Tokuro Suzuki), and five from the U.S.A. (Hallowel Davis, James Jerger, Jozef J. Zwislowski, Aram Florig, and Peter Dallos).

Prof. Engstrom's Visit to Italy

During his stay in Italy Prof. Engstrom also visited Catania. On March 24, in the public hall of the Catania University, he presented the tutorial lecture, "The Normal and Pathological Organ of Corti".

His studies and the significant steps in his career were illustrated by Giovan Battista Catalano, Head of the Otorhinolaryngology Clinic at the University of Catania.

Equipment (Continued from Page 6)

of the emitter. However, interactions between rooms with reflective surfaces, obstacles, emitter placement, and high intensity sun light will require empirical verification.

Applications: The categories of application are broad, ranging from the ability to communicate from one speaker to a group of listeners in large room situations to those where individual communicative enhancement needs may be obtained from a personal system. Examples of the former include the following: 1) classrooms for the hearing impaired, 2) business and industrial conference rooms, 3) courtrooms, 4) houses of worship, 5) theaters and concert halls, 6) university and medical lecture halls and, 7) hotel and other conference centers. An advantage for the individual wearing hearing aids is that the infrared receiver can be coupled to his aid through either an induction or a direct line input.

Advantages: Two major advantages of this system when compared to other large room assistive devices are the ease of installation and the reasonable cost for the diversity of use and quality of signal derived. Additional benefits involve the minimal safeguards required to eliminate outside interference from other infrared

systems. One large room may be easily designed to incorporate two infrared systems without concern for signal interaction. Also, there is never interference from AM and FM transmissions. Individual portable systems have been successfully used to 1) amplify telephone signals, 2) enhance communication in hospitals and nursing homes where restricted listening is preferred, 3) sharpen communication during travel where the elimination of unwanted noise is desired, and 4) facilitate the reception of radio and TV signals. Another benefit to the consumer is the compatibility of infrared receivers between manufacturers due to the present use of a common carrier frequency.

Disadvantages: Although manufacturers may claim success with outdoor usage in sunlight conditions, signal integrity is diminished as the intensity of the interfering light increases. The general rule requires that when an interfering light source creates transmission difficulties, it is necessary to intensify the generating capability of the transmitter through additional emitters. A minor disadvantage occurs when considering installation where obstacles may minimize the homogeneity of infrared illumination. In these conditions, it is recommended that the transmitter be located high above the floor of reception or, when necessary, that the signal strength be augmented through additional emitters.

Large Area Systems-Information:

Transmitter:
 No. of light emitting diodes 90-143
 Power requirement 120V/60 Hz
 Audio signal input 30mV-3mV
 Frequency response 40-15K Hz
 Infrared output 4k-4.5k sq. ft.*
 Carrier frequency 95k or 250k Hz
 Cost \$900-\$1300
**Greater output is available through slave or additional emitter/transmitter units.*

Receiver:
 Type diotic-dichotic
 Frequency response 50-8K Hz
 MPO 112 dB SPL
 S/N 50dB
 Battery AAA/recharge
 Operating time 5-10 hr
 Cost \$90-\$150

Large room assistive listening devices are produced by the following manufacturers: Controlonics (Sound Plus) and Sennheiser (Siemens).

Note:
 There is a conspicuous lack of information regarding standardized assessment for comparative purposes. Until standards are developed, the consumer must rely on subjective appraisal.

Subjects Editor: Frank Brister

1985 AAS MEETING AVAILABLE ON VIDEOTAPE

The 1985 meeting of the American Auditory Society is now available on videotape.

The videotape is approximately 6 hours in duration. It includes the Carhart Memorial Lecture by Sam Lybarger, B.S., entitled

"COUPLER TO INSERTION RESPONSE FACTORS"

The videotape is available in VHS format only. To order, send the specified amount after checking one of the below:

I am sending a T-120 blank videotape. Please duplicate the 1985 convention tape and return it to me. Cost=\$25.00

I am not sending a blank videotape. Please send me a copy of the convention tape. Cost = \$35.00.

Make check payable to the American Auditory Society.

Send order to: Michael F. Seidemann
 Jo Achim Eye, Ear, Nose
 and Throat Hospital
 145 Elk Place
 New Orleans, LA 70112

The videotape should be mailed to:

Please allow 4-6 weeks for delivery.

AUDITEC (Continued from Page 6)

same parts, the metallic ones, should be demagnetized periodically, probably at the same time one cleans the heads. Demagnetizers for this purpose are available at the same source. Again, just follow directions. About once a year or oftener if used a lot, the heads must be re-aligned. It can be done "in-house" with a good alignment tape and a pure-tone oscillator, but professional help is the better bet. If anyone wants to know more, call me. I'll be happy to tell the hows and wherefores.

Do you have an 800 number?

No, but we accept collect calls.

Do you have much problem with people copying your tapes?

That's hard to tell. I know that our tapes are being copied, but I can't tell how many or how much. I get a little peeved when it comes to pirating of my tapes. I know that each individual copier believes that he or she is not hurting Auditec when they copy one or two tapes. This is just not realistic. I had on audiologist call with a complaint, noting that she was in the process of copying one of our tapes (a copyrighted one at that)! When I attempted to chastize her, she said, "Well, everybody does it." Thank goodness everybody doesn't, because if everybody did, I would be out of business. This market is very small, and each copy represents a small but significant part of my yearly output.

What about the size of your market?

The number of potential customers out there is extremely small relative to the general population. Record companies make a big deal out of selling a million copies of a recording, I get excited if we sell a hundred of one tape in a year! Some of our recordings are so popular that we may sell one in a year! Anyone with any sense looks at the size of this market and says "no way!" But I have no sense, so here I am.

What do you see coming in the future?

Well, the future is here. It is digitized recordings, of which compact disks are an example. Computers have the capacity to take analog signals and digitize them, store them on some medium in digital form which can be "read" and translated into analog form for "consumption."

What are the advantages of digitized recordings?

Well, the signal to noise ratio is extremely good, there is no tape hiss, there is no print-through, there is a very large dynamic range available and the digitizing process allows almost unlimited manipulation of the signal, far beyond the capabilities of an analog system.

Has Auditec gone to compact disks?

No. There are two primary reasons why we haven't taken that step. First, the demand is not there yet. Second, the cost is relatively high when related to the size of our market, which, as I stated earlier, is extremely small. Also, there are other media which are either available now or should be available soon which may suit our market better.

Are your customers limited to the United States?

No, we have a comparatively large export market. We have a large number of Canadian customers, and we also serve Australia and New Zealand. Some of our

tapes are being used in England and a few of our Spanish and French tapes and non-verbal tapes have gone to other countries as well.

What has been most rewarding about Auditec to you?

Yes, "rewarding" is a good word. I have derived a great deal of satisfaction from Auditec. It has been suggested by some that Auditec is performing a needed and valuable service for the audiological community. I had no altruistic motives in mind when I began this business. I saw a void and have tried to fill it. I have found that Auditec seems to have become syn-

onymous with recorded auditory tests, and this gives me a warm glow. And I still get a thrill out of seeing our name in print, when our tapes have been employed in a research project, for instance.

What are your plans for the future?

Continued growth. Business will not grow on its own, however, I have several projects "in the fire" and I am always on the lookout for new product ideas. If there are any readers who have ideas which they think might be marketable, I would like to talk with them. We have a number of tests in our line which have been developed by others and there is always room for more.

Dr. Carver, one final question. If you had it to do over, would you?

No question about it. I would have started earlier, however. Auditec has been the best thing that has happened to me. Beyond what I just said about personal satisfaction, I also have found that being my own boss is "the only way to fly." I would find it extremely difficult, if not impossible, to go to work for someone else again.

Thank you, Dr. Carver.

On the contrary, thank you.

Last year's "Run for Better Hearing" participants included both marathoners and joggers running a three-mile "fun run" along Lake Superior the day before the marathon. Fun run finishers (above) represented all hearing help disciplines.

8th Annual Run for Better Hearing...

Health Care Providers Running 26 Miles for Hearing Awareness

A 1986 "Run for Better Hearing" team of doctors, audiologists, hearing aid specialists, manufacturers, suppliers and researchers will each run a marathon to focus public attention on available hearing help. They personify the interdisciplinary support generated for the cost-effective public education program of the Better Hearing Institute.

Now in its eighth year, the Run is a fund-raising effort to strengthen BHI hearing awareness projects. Broadcasters and print media have donated the equivalent of more than \$118 million in commercial time and space to BHI hearing help messages. More than \$16 million was generated in the past 12 months alone. BHI's program has been spearheaded by famous Americans who overcame hearing loss. They include Art Carney, Norm Crosby, Phyllis Diller, Nanette Fabray, Lou Ferrigno, Henry Fonda, Lorne Greene, Florence Henderson, Bob Hope, Richard Thomas, Charlene Tilton, Keenan Wynn, and many others.

1986's Run doubleheader features BHI executive director Joe Rizzo in his seventh Boston Marathon on April 14. Then on June 21, in Duluth, MN, Joe will be joined in Grandma's Marathon by hearing help providers from across the U.S. and Canada. As in past years, *Hearing Instruments* magazine will promote and host Duluth Run activities, and the *Hearing Journal*, Ayer, MA, will extend its special support at the Boston Marathon.

Steering Committee

Organizing and coordinating this year's campaign is a steering committee that includes Al Bruce, chairman, Starkey; Jim Anderson, Qualitone; Pat Koepke, Dahlberg; Bud Raas, Earmold Design; Bob Tischbein, Starkey; and Cindy Werner, Duracell/Activair.

"BHI's program runs strong because of financial support from hearing help providers," said Bruce. "We therefore urge everyone to pledge to this year's campaign. Your tax-deductible contribution will reach far beyond the 26 miles, 385 yards that our runners will tackle this year."

Supporting Companies

Supporting members to date: Activair, Argosy, Audio-Aid, Beltone, Bernafon, Best Labs/Fidelity of Florida, Bosch, Dahlberg, Danavox, Emtech, Eveready, Fidelity Hearing Instruments, Finetone, Hal-Hen/Widex, Hearing Services Inc., Hearing Technology Inc., Knowles Electronics, Lang Hearing Instruments, Magnatone, Maico, National Hearing Aid Labs, Oticon, Phonic Ear, Qualitone, Ray-O-Vac, RCI, Resistance Technology, Rexton, Rion, Siemens, Starkey, and Unitron.

Beltone Opened '86 BDTAA Nominations

The 1986 search for an outstanding audiology instructor began with the opening of nominations for this year's Beltone Distinguished Teaching Award in Audiology (BDTAA).

The BDTAA is the only teaching award bestowed in the field of audiology. To be eligible, instructors must be nominated by a current or former student and have five

Foundation

(Continued from Page 3)

auspices of the International Hearing Symposium. Activities on this day will include an admirable cast of faculty participants and will delve further into topics of current audiology and technological interest, as well as into dispensing and marketing strategies, practices, and trends for the future.

Some hands-on experience for ITE and earmold modification will also be available in the International Hearing Foundation's Temporal Bone Dissection Lab (numbers permitting), making this truly a well-rounded symposium/workshop.

Information and/or registration materials may be obtained by calling Anna Douglas at (612) 339-2120 or by writing to the International Hearing Foundation, 701-25th Avenue South, Minneapolis, Minnesota 55454.

New Hospital Program Created

Suburban Hospital in Bethesda has initiated an unusual support program for patients who are hearing impaired. The Hearing Impaired Program is designed to eliminate misunderstandings between patients and hospital staff and to relieve hearing impaired patients' anxiety and increased sense of isolation in the hospital environment.

Within its first 50 days, the program served 85 patients. Currently as many as four patients a day join the program.

Coordinated by the hospital's neurotology unit, the program is for patients with any degree of hearing impairment from minor difficulty to total deafness. There is no charge to patients who use this service.

People with hearing impairments often are faced with communication problems in the hospital setting—lack of their usual hearing aids (especially just prior to surgery and in the recovery room) and masks over the faces of nurses and physicians.

Upon admission to the hospital, all patients are asked if they have a hearing problem. The medical charts of patients who join the program are labeled with the international symbol for hearing impairment. Similar signs are placed in their rooms and on their beds.

Hospital staff have received extensive training in methods to clarify and simplify communications with hearing impaired patients—getting the patient's attention, speaking deliberately, not shouting, writing messages when necessary.

Listening devices, telephone receiver amplifiers and TDD (telecommunication devices for the deaf) are available for these patients, and sign interpreters for deaf patients are on call.

Other services of Suburban's neurotology unit include complete hearing evaluation; ENG (electronystagmography), which is a test of inner ear function and balance control centers of the brain; ABR (auditory brain stem response), which is a test of neural activity in the auditory brain stem; evaluation for selection of hearing aids; and monitoring of ototoxicity to drug therapy.

For further information about the Hearing Impaired Program, call Kathy Eccard, M.S., CCC-A 301/530-3165.

years', or more experience in teaching audiology.

About 10,000 brochures containing nomination forms were mailed by Beltone to audiologists, audiology instructors and department heads at universities across the country. Deadline for nominations was April 15, 1986.

The nomination form is one of seven factors weighed by the judges to determine a winner. The other six factors are a required essay, curriculum vitae, former and current student evaluations, contributions to audiology, audiology department head evaluation and faculty evaluations.

The 1986 judging panel is composed of 10 outstanding professionals from the field of audiology—including the 1984 and 1985 BDTAA recipients—plus one student representative selected by the National

Student Speech, Language, and Hearing Association. The judges are Charles Berlin, Ph.D. (1984 BDTAA recipient), Louisiana State University; Michael Chial, Ph.D., Michigan State University; Marion P. Downs, M.A., University of Colorado; Renee Engelstein (student), Queens College of City University of New York; David Lipscomb, Ph.D. (1985 BDTAA recipient), University of Tennessee; Frank Musiek, Ph.D., Dartmouth-Hitchcock Medical Center; Jerry Northern, Ph.D., University of Colorado; Njeri Nuru, Ph.D., Howard University; William Rintelmann, Ph.D., Wayne State University; Ralph Rupp, Ph.D., University of Michigan; and Roger Ruth, Ph.D., University of Virginia Medical Center.

Announcement of the 1986 BDTAA recipient will be made at the November

meeting of the American Auditory Society. Beltone will award the winner \$1000 cash and a commemorative plaque. The fir will also host a banquet in the winner honor at his or her university and will sponsor three lectures by the instructor leading universities around the country. The winning instructor will also be invited to sit on the 1987 judging panel.

In addition, the award package includes a \$2500 scholarship from Beltone to the audiology department at the recipient university, and a \$100 cash award to the person nominating the recipient.

The 1986 winner will be the sixth audiology instructor honored through the program. Beltone established the BDTAA program to recognize contributions by the teaching profession in the field of audiology.

FACT SHEET

INTERNATIONAL HEARING FOUNDATION

WHAT IS IHF?

The INTERNATIONAL HEARING FOUNDATION (IHF) is a charitable, nonprofit organization dedicated to improving the lives of the hearing impaired.

IHF is especially committed to increasing public awareness of hearing problems and to the financial support of hearing research and education.

Deafness, tinnitus (ear-noise), and vertigo (dizziness) are examples of IHF's special interests.

The foundation's activities are local, national and international in scope.

- The International Hearing Foundation was granted tax-exempt status by the State of Minnesota April 9, 1985.
- IHF conceived, produced and owns a telethon, "Sentimental Sounds", at the cost of \$200,000.
- The 1985 telethon, viewed in March in Minnesota and the neighboring states on Channel 5, resulted in gross income of \$110,000.
- Money from the telethon attributed to the work of the Lions Clubs of Minnesota totaled \$49,500. This amount went directly to the Lions Center at the University of Minnesota for research.
- IHF is the recipient of a grant for \$35,000 to support an IHF Research Scholar for research in Otitis Media.
- IHF is the recipient of a \$60,000 grant to help construct the IHF Teaching Laboratory in Minneapolis.
- IHF will annually sponsor the FIEESE PRIZE, a new award for advancements in biomedical and technological hearing research. The recipient, chosen by an international scientific committee, will receive a cash award plus a 3-ounce gold medal and a tax-exempt bond.
- An annual social fund-raising event will be held in downtown Minneapolis on the Monday of Aquatennial. The 1985 event resulted in over \$9,000 income and garnered tremendous publicity.
- An officer of IHF will accompany Miss Deaf Minnesota in the two annual Aquatennial parades which is viewed by a combined street and television audience of over one and one-half million people.
- The IHF Board of Directors, which includes prominent otolaryngologists, scholars and community leaders from all around the world, meets semi-annually in March and September.
- IHF supports and sponsors education and research in Minnesota and, through its programs (telethon) and Board members and colleagues elsewhere, encourages such activities in other states and countries.

International Hearing Foundation, 3100 W. Lake St., Minneapolis, MN 55416 • 612/927-9220

The 1984 Amplifon Research and Studies Center International Prize Awarded

Scientists are beginning to find out the secrets of the hearing system.

More than one hundred years have elapsed since the Italian scientist Alfonso Corti (1822-1876) discovered the spiral organ of the ear, but only recently have scientists begun to understand the many mechanisms of our highly complex hearing system.

Peter Dallos, professor of otolaryngology, neurobiology, and physiology at Northwestern University in Evanston, Illinois, U.S.A., was recently awarded the 14th CRS Amplifon International Prize amounting to ten million Italian liras.

Dallos has been, since the 60's, the coordinator of all basic research in this field, supported by several annual allocations totalling more than one million U.S. dollars. Through his studies and research he came to revolutionary conclusions, concentrating his efforts on the inner ear (the labyrinth, made up of the vestibule and the cochlea) and above all on the organ of Corti, which is the real sensorial organ of the hearing system.

This highly complex and extremely delicate structure is placed in a cave within the temporal bone, which is the hardest bone in the human body. This structure is filled with a water-like fluid, called endolymph, and with thousands of sensory receptor hair cells, which transmit sound

and nervous impulses along the auditory nerves up to the brain, where every acoustic message, even every minimum sound, is selected and interpreted.

The hair cells can be divided into "inner" hair cells (approximately thirty-five hundred) and "outer" hair cells (approximately fourteen thousand). It is on these intriguing structures that Dallos has concentrated his attention, regarding them as "marvelous information transmitters and likely motor devices."

Ingenious work by Dallos and his associates elucidated the effects of chemically induced outer hair cell destruction on hearing. In this work they used computers to analyze data obtained from both cadaver and animal (mainly chinchilla) ears.

Georg von Békésy, in his 1961 Nobel prize winning research, demonstrated that acoustic stimuli initiate "traveling waves" which, in turn, mechanically distort hair cells. This mechanical activity somehow triggers action potentials in the acoustic nerve. Dallos has emphasized that metabolic energy is the driving force behind the generation of nerve impulses.

The ear is a miniature masterpiece because it is enclosed within a space as small as a hazel nut. However, even in this tiny organ, electric, metabolic, and

biochemical processes take place. The mechanisms are in part still unknown, though experimental evidence shows, as Dallos put it, that "virtually any damage to the auditory system is first of all evidenced by the destruction of the outer hair cells. Drugs, noise, aging, and trauma, all affect outer hair cells before influencing other structures. The loss of outer hair cells begins at a very early age in humans and tends to progress inexorably in persons over age sixty-five."

All this implies an altered, abnormal processing of sounds by the inner hair cells, which opens new fields of research and probably new prospects for better diagnosis and treatment of such hearing disorders.

This means that scientists are now beginning to understand how the inner ear converts sound vibrations into nervous impulses. At the same time attempts are being made to interpret the meaning of the electric or potential signals emitted by the inner ear.

In this field there have so far been two major breakthroughs. One is represented by the tiny transistor hearing devices which can be hidden in the frame of glasses, behind, or even inside the ear, and are, therefore, hardly visible. The

second breakthrough was achieved through the development of biomedical techniques which enabled microsurgons to operate within very small cavities, thus allowing transplantation of one or more of the middle ear bones (hammer, incus and stirrup).

But it is, above all, through the study of the inner ear, carried out by Dallos and his collaborators, that ENT surgeons hope to develop new solutions to many fundamental problems regarding hearing loss and hearing disorders.

So far scientists have not been able to understand how an average grown-up person can store in his/her memory as many as 400,000 sounds, different from one another in frequency, quality and intensity. Another unsolved riddle is how a person with normal hearing can discern any sound ranging from 16 to 28,000 vibrations per second, whereas most animals have a much higher range (a cat, for example, can hear sounds with a frequency ranging between 60 and 65,000 vibrations per second).

Finally, scientists still have to better understand how calcium spreads through the most critical parts of the ear and what role proteins play in the cochlear mechanics at the base of the cilia of the hair cells.

A lecture delivered by the U.S. scientist Peter Dallos, who has been awarded the 1984 CRS Amplifon International Prize.

AAS Meeting
November 20th*

WE'RE FLEXIBLE!

The new Widex M1 enables you to customize its response with two standard internal adjustments for gain/output and tone.

Available in both a universal fit and custom versions, the M1 also features:

- 20dB fixed compression
- Removable wax guard
- Vertical volume control
- Low-profile faceplate

At Widex, our standard is excellence. So you can be assured that with every Widex M1 you dispense, excellence is standard. And you can be assured that you're dispensing the only truly flexible canal instrument available today.

The Widex Hearing Aid Company
Continuing to set the industry's standard for excellence.

1986 CONVENTION ISSUE

CORTI'S ORGAN

The Official House Organ of The American Auditory Society

Volume 11, No. 2

Fall 1986

*Dinner and
Entertainment
in Greektown*

**Mykonos Supper Club
454 East Lafayette
Detroit, Michigan**

Dr. Joseph E. Hawkins

Detroit To Host Annual 1986 AAS Convention

The 13th annual meeting of the American Auditory Society (AAS) will be held in Detroit on Thursday, November 20, 1986, in the auditorium of the Children's Hospital of Michigan. AAS President Don Worthington's introductory remarks at 8:30 A.M. will be followed by an exciting series of 20 scientific papers lasting until about 5:00 P.M. A highlight of the day will be Dr. Joseph E. Hawkins' Carhart Memorial Lecture entitled "Traces of Age in the Ear and the Eye."

Following the meeting there will be an evening of Greek food and entertainment at Mykonos Supper Club. It should be a rewarding day and night for AAS members, many of whom will subsequently attend the annual American Speech/Language/Hearing Association (ASHA) meeting, which will be held at Cobo Hall, November 21-24.

IVth International Symposium On Audiological Medicine

The International Association of Physicians in Audiology (I.A.P.A.) will have its Fourth Symposium in Tenerife, Canary Islands, Spain, November 8-13, 1987.

The scientific programme will include round table discussions with invited speakers together with free papers sessions on the two main themes: "The State of the Art of Audiological Diagnosis" and Imaging in Audiology: X-Ray and Other Techniques in the Diagnosis of Auditory Disorders."

For further information, please contact Dr. Jose Barajas, Perez de Rozas, 8, 38004 Santa Cruz de Tenerife, Spain.

AURAL REHABILITATION FORUM

Editor's note: In the last issue of Corti's Organ this new feature was begun. The article in that issue was presented by Ronald Schow as a part of a conference on aural rehabilitation held in 1983 at Winter Park, Colorado.

Initial articles in this series will investigate intervention services specific to elderly clients. In order for this forum to continue, other papers must be generated. Areas of interest for our readers would include pediatrics or cochlear implantation. Let the editors hear from you!

Motivating the Hard of Hearing: A Contrast in Techniques

Thayne C. Smedley
Nu Ear Electronics
Idaho State University

(Second in a series of three.)

Abstract

The enormous pool of hearing-impaired elderly who have \$500 billion in buying power represent a powerful marketing incentive for the hearing aid industry. A promotional technique used to reach and motivate potential hearing aid users is described and contrasted with traditional efforts by audiologists. The suggestion is made that clinical audiologists will need to achieve a higher visibility profile—and perhaps adopt certain promotional techniques—if they hope to replace the hearing aid dealer as the primary source of hearing aid help for the majority of impaired adults.

There are believed to be over 11 million people in the United States who are potential hearing aid users among an ever-growing senior citizen population with \$500 billion in buying power (Radcliffe & Mahon, 1983). This body of prospects represents a very powerful marketing incentive for hearing aid manufacturers.

In this presentation I will describe a direct mail marketing technique used in the hearing aid industry which has proved to be very effective in reaching and motivating hard of hearing adults. I am not pretending that what I am about to describe represents the ideal or even the best method for motivating the hard of hearing, or that it will be necessarily well received by clinical and rehabilitative audiologists in general. This approach, however, does achieve certain objectives, particularly those of the hearing aid industry, and it may have some implications for audiologists who wish to get more directly involved in hearing aid programs.

An independent hearing aid dispenser agrees to be a cooperating partner with a hearing aid manufacturer sponsoring a special, short-term sales promotion, lasting usually three days. Local residents are invited by personal letter to come into the dealer's office for a free hearing test and an opportunity to examine the latest hearing devices. The event is called a "Special Hearing Aid Consultation." The Special Consultation always features a factory representative, who, ostensibly, is a trained and experienced specialist in remediating hearing loss with amplification. This consultant usually has had extensive experience with hard-of-hearing persons, but is sent primarily because of skill in selling.

In this program, the manufacturer prints the letters, stuffs them into pre-labeled envelopes and ships them as a unit to the dealer, who in turn takes them to the local post office for mailing into the community. Names of local senior citizens, obtained from commercially available national registers, are supplied by the manufacturer.

Although the letter does not contain any false statements, it uses phrases such as "hearing tests at no charge," designed as enticements and intended to elicit a favorable response. Other incentives are also included, such as the availability of refreshments and free gifts for those who attend, plus special discounts on batteries. A final motivational device is the inclusion of an endorsement of the testing program and manufacturer's product by a national celebrity. This endorsement creates interest in the letter and lends credibility to the invitation, the examination, and the products as well.

In the program I am describing, the endorsement comes from Art Linkletter, a TV and radio personality well known to senior citizens. Linkletter's picture is printed on the heading of the letter, and his printed message promotes the value of the hearing tests and invites the readers to take advantage of the opportunity to have their hearing evaluated. The impact of the Linkletter endorsement is substantial. A recent report illustrates this point:

A woman in the Northwest walked into one of these Special Consultations with her elderly mother, letter in hand, and said, "I have been trying for years to get my mother to do something about her hearing. I'm tired of

New Feature Editor Joins Staff

Matt Smith, an audiologist from Albuquerque, New Mexico and long time member of AAS, has joined *Corti's* Editorial Staff as a Feature Editor. Matt will "take charge" of two new columns to appear in *Corti's*, beginning with our next issue.

One, entitled "Name That Lesion", will be included in each issue. Case history, clinical data, and other relevant information will be presented which describes a particular auditory disorder or lesion. The intent of this column is for readers to use all their professional expertise, intuition, or whatever thought process they wish to "diagnose" the lesion being described. Sounds like fun, but don't worry, the "answer" will be given in each issue.

Matt's second column will be one which will appear now and again. Entitled "Audiology Trivia", questions will be asked which really test our skills. Do you know what year the first hearing aid was manufactured? This column will answer this question and more!!

Matt Smith is certainly a well-rounded professional. In addition to having a private practice, he is President of Cyber-smith, an audiometric manufacturing and consulting firm. His wealth of experience, as well as his sharp wit and humor, make him the ideal creator for these two columns.

Welcome, Matt, to the Editorial Staff. We'll all be watching for great things to come.

Corti's Organ Celebrates Anniversary

According to some of our "old timer" members, this year marks the 10th Anniversary for *Corti's Organ*, plus or minus a year or two. This is certainly a landmark occasion worth celebrating and rising to. In tribute to *Corti's* first decade, the Editorial Staff has something special planned.

An upcoming issue of *Corti's* will be dedicated to our past. Historical facts about the Society, old pictures, past articles of contemporary relevance, *Corti's* nostalgia will all be included.

For our "seasoned" readers, the memories should be exciting. For our "junior" readers, the historical perspective should be educational.

If you have any old convention pictures or information from our past, please send it to one of *Corti's* Editors.

From The Editor

Let me begin by thanking those individuals who have responded to my request for contributions to *Corti's*. As Editor, I am pleased to find members who are willing to "pitch in." But we still have a long way to go to keep *Corti's* from being simply a calendar of events or directory listing. Contributions of all varieties are needed, particularly reports of case studies, light research, equipment review, etc. Don't be intimidated by the threat of "journal style." Develop a new way of thinking - "*Corti's* Style!!"

A new dimension that accidentally evolved in our last issue was a "Letter to the Editor" column. This is a segment the Editorial Board would like to continue. Maybe you have an issue important to you, a positive (or negative) reaction to AAS business, a "cause to preach", a request for information. *Corti's* can be your vehicle for communication.

As members, we all have a voice and a responsibility as professionals. Remember, the Editorial Board should represent the readers and their interests. That's you!! So keep those cards and letters coming (and other contributions, too)!!

Endowment Fund Named For M.P. Downs

The University of Colorado Health Sciences Center and the University of Colorado Foundation, Inc. have established an endowment fund in recognition and appreciation for the outstanding contributions of Marion Downs and her lifelong efforts on behalf of children with hearing impairment. This fund was created to assist in the development of the Marion Downs Children's Hearing Center.

Funds will support multidisciplinary clinical services for hearing impaired infants and children, including patient care, research in childhood deafness and educational activities. In addition, with the goal of \$350,000, the foundation will award an annual Pediatric Audiology Fellow selected from national applications. This endowment will provide a year of financial support to a practicing audiologist who desires additional clinical training and research opportunity in pediatric audiology.

Marion Downs, Professor Emerita of Otolaryngology at the University of Colorado Health Sciences Center is certainly an exemplary professional who has devoted her life to the hearing handicapped. She has pioneered, developed and evaluated techniques for her work in the area of early identification of hearing loss and in infant hearing screening. Her publications and teaching have brought worldwide attention to the importance of early habilitation for deafness and alerted the medical world to the developmental problems associated with childhood deafness.

Marion Downs is recognized as an outstanding educator, clinician, author and progressive advocate for the hearing impaired. Her professional colleagues have honored her with numerous awards and praises. The Marion Downs Children's Hearing Center Fund is just one more way of testifying to this professional's accomplishments. If you would like further information on the fund or would like to make a contribution you may contact Jerry Northern, Ph.D., Professor and Division Head of Audiology at (303) 394-7856, University of Colorado, Health Science Center, 4200 J. Ninth Ave., Box A-065, Denver, CO 80262.

Marion, AAS congratulates you!!!

Harmony Among Dispensers Urged

Numerous AAS members, including Deborah Price and Rick Pimentel (picture below), attended the Spring Conference of the Academy of Dispensing Audiologists (ADA) at Lake of the Ozarks, Missouri. A striking keynote address, entitled "What Was, What Is, and What May Be," was delivered by the Academy's president, Herbert F. McCollom, Jr. Mr. McCollom argued that the various kinds of professionals who fit and dispense hearing aids should stop denigrating each other and work together to provide optimal service to the hearing impaired public. He discussed a number of possible untoward consequences of the present "war." For example, if the dispensers are unable to work out solutions to their conflicts, the federal government may impose unacceptable solutions of its own. Another risk of continuing the battle is that disarray in the hearing aid market may attract new competitors to the scene. Mr. McCollom drew analogies between the infighting of hearing aid dispensers and similar warring among ophthalmologists, optometrists, and opticians, and among MD's, osteopaths, and chiropractors. His paper has been printed in the July, 1986 issue of *The Hearing Journal*.

Barbara Gount, Deborah Price, Rick Pimental attended ADA 1986 meeting.

Aural Rehabilitation

(continued from page 1)

yelling at her. When the letter arrived from Mr. Linkletter inviting us in for a hearing test, Mother said, 'If Art Linkletter's behind this, it must be OK. I guess I'll go and get my hearing fixed'."

For any given Special Consultation, typically 5,000 to 7,000 of these letters are mailed to senior citizens of a given community. While certain parts of the letter may violate our ethical or professional sensitivities, we must keep in mind that it tends to get results where other approaches have failed.

During the days of the promotion, respondents are seen on hourly appointments, or more frequently when the demand requires it. Each person receives a cursory otoscopic examination, a brief but intensive history is taken using a standard questionnaire, and then each person is tested for hearing loss. If significant hearing impairment is found, the prospect is introduced to the various hearing aids available from the sponsoring manufacturer and is encouraged to purchase one or two hearing instruments, depending on the loss.

Now, whether or not we agree entirely with the approach I have described, let me assure you that this type of promotional campaign is having great impact throughout the country. Currently, about 150 of these Special Consultations are being held every month by this manufacturer throughout the United States, totaling 750,000 pieces of mail monthly. This represents a rate of 9 million letters mailed to potential consumers annually, and this rate is double that of the previous year and still growing! Over the next few years it would appear that millions upon millions will receive letters from Art Linkletter encouraging them to think seriously about their hearing and to have it tested by the local dealer if they suspect a problem. And, this rather substantial campaign represents the efforts of one single company. Increasing numbers of hearing aid manufacturers, of which there are about 50, are using this or similar promotional formats to command a greater share of the market. If measured in terms of hearing aid sales, the mass mailing approach is clearly working. In the long run it may not be the best remedial service available, but such programs are going to continue to go forward at an ever-increasing tempo.

Hearing aid delivery systems in this country seem to fall generally into two categories: those which are "passive" in nature, and those which are more "active". Passive systems are those represented by agencies, clinics, and offices which have a trained staff dedicated to helping the hard of hearing, but which do very little advertising. These offices are primarily rehabilitative in intent, and their first priority

is to ameliorate the effects of hearing impairment. Most of the personnel in these agencies have received extensive technical training, including graduate degrees and special certificates awarded by national professional societies which attest to their qualifications to assist the hard of hearing better than anyone else.

The encouragement or motivation these offices are able to extend to the hard of hearing, however, is limited largely to the shingle that hangs above their office doors! It is considered improper to advertise their services to any great extent, and the term "promotion" is generally foreign to the common vernacular of the office. It seems paradoxical that this cadre of trained professionals who must sit patiently and wait for the hearing-impaired public to find the path to their door, represents, with some exceptions, a distribution system that is a mere eddy alongside the main stream of hearing aid delivery in our country. I believe it is still true today that traditional hearing aid dispensing offices, which take an active rather than passive approach to helping the hard of hearing, have the greatest influence among those with hearing loss and render the greatest assistance to the hearing impaired, if that assistance is measured by the number of units of hearing aids dispensed. Whether we like to admit it or not, a majority of the hearing impaired adults in the United States receive such assistance from hearing aid stores, staffed by personnel of varying degrees of qualifications whose background and work experience is typically in sales rather than in rehabilitative activities. In my opinion, they basically represent a business enterprise which just happens to involve hearing rehabilitation. Nevertheless, many of them are very skillful and have loyal customers who repeat purchases of hearing aids over and over again, sometimes extending to two or three generations in one family.

We must ask, "How do these offices, staffed with personnel who as a group have fewer degrees and credentials than we do, achieve such great success in reaching out to and motivating the hard of hearing?" Their formula, I believe, can be expressed rather simply in three words: promotion, promotion, and promotion! Their approach is far from passive. It is indeed active.

What do we as audiologists do about the situation? What do we do with the realization that some senior citizen in our town, whose hearing has finally dimmed to the point of awareness, will respond to some advertising impression solidly planted there over the years from hundreds of effective messages he has received from the hearing aid industry; and in all likelihood will eventually walk into the local dealer's office for assistance without even giving us a thought?

I don't have a solution, but my inclination after being associated directly with the hearing aid industry for the past three years is that we had better start using the word "promotion" in our daily communications. We need high level promotion that doesn't seriously violate our sense of ethics, but promotion nevertheless. If we ever hope to move out of the eddy into the main stream of hearing aid delivery, we must become much more visible in the public eye. We need greater direct involvement in hearing aid dispensing programs. We must not remain passive in our approach or we will forever remain in the dust of the aggressive promoters who many people think are the only source of help for their hearing problem.

Society Member Honored by State

Sharon Graham, an active member of AAS for several years, was selected as Arkansas' nominee for the Louis DiCarlo Clinical Achievement Award. For the last 3 years, the American Speech-Language-Hearing Foundation has recognized an individual whose recent accomplishments in the field have been landmark contributions. These contributions may be in clinical achievement or in research.

Each state is asked to select one individual who has shown outstanding achievements in recent years in a particular area. From the individual state nominees, the Foundation chooses one as the National DiCarlo Award designee. Each individual nominee is also recognized by the Foundation with a cash award and a Certificate of Achievement.

Sharon Graham was selected as Arkansas' DiCarlo Award nominee. Ms. Graham is the Research Audiologist for the Ear and Nose-Throat Clinic in Little Rock, Arkansas. In addition, she is Co-

ordinator of the Cochlear Implant Investigation Project.

Ms. Graham was chosen for her outstanding clinical achievement in the area of deafness research. Her recent contributions include numerous studies, papers, and presentations specific to cochlear implantation. She has examined varying aspects of this relatively new procedure, including the medical, clinical, and rehabilitative variables relating to the process. Her work has been the foundation of much of the recent advancements in the assessment and audiological management of this population.

Ms. Graham is truly the total professional. Arkansas' selection of her as the state's 1986 Louis DiCarlo Clinical Achievement Award nominee was an easy one. Ms. Graham is certainly one of the field's leading contributors. Congratulations, Sharon, on this deserved recognition!!

Cochlear Implants in Children: A Multidisciplinary Colloquium

A colloquium on cochlear implants in children, sponsored by the Cochlear Corporation, was held February 20-22, 1986, at Durango, Colorado. The colloquium's purpose was to establish guidelines for the implantation of children based on the ideas and experiences of the specialists, to discuss the many controversial issues surrounding cochlear implantation in children, and to summarize the philosophies surrounding these issues.

The meeting brought together more than 40 experts from diverse hearing health disciplines, including otology, hearing and speech sciences, audiology, speech pathology, linguistics, statistics, psychology, and psychoacoustics. The selection of the participants was based on their particular interest and expertise in dealing with the deaf child, rather than on their prior experience with cochlear implants.

Eight committees met to debate a variety of topics ranging from patient selection and pre-and postoperative evaluation procedures, to rehabilitation and the key underlying issue of the safety of implanting cochlear prostheses in children aged 2-17. Each chairperson developed a set of questions to guide discussions. Committees met independently for two days, and, on the third day, the individual committee summaries were presented to the entire group in a large plenary session. A consensus was reached based on position papers presented by the committee chairpersons.

According to colloquium participants, a team approach to cochlear implantations is of prime importance. The team should include other child specialists to enhance the well established teams already in place for adult programs. Appropriate specialists mentioned at the colloquium include school personnel, teachers, school psychologists, as well as child psychologists and social workers. Decisions would be made by the entire team.

Colloquium committees discussed speech-language considerations and many aspects of implantation: physical, audiological, intellectual, and developmental. It was agreed that two years should be the minimum age of potential implant candidates. According to colloquium surgeons, it is technically feasible to implant young children. The major limiting factor is skull maturation. The majority suggest that two years of age is the youngest age at which adequate and reliable audiologic evaluation and complete preoperative workup are possible. There was unanimous agreement that hearing loss for these young candidates should be sensorineural, bilateral, and either profound or total. Committee members also agreed that a potential surgical patient be one who has failed to benefit from appropriate conventional amplification and training. The committees worked to identify objective means for determining whether or not a child is making auditory progress. Lack of auditory development was defined as a child's inability to discriminate spectral information of the segmental aspects of speech following at least one year of effective training with appropriately fitted hearing aids. A child's inadequate progress in verbal language skill development is another hallmark of a lack of auditory development.

Colloquium participants determined that the child should have at least an average IQ through the initial stages of implant studies and be free of additional handicaps that might adversely affect potential success with the implant. The recurring theme was that children free of motor and intellectual disability are needed during the critical early stages of implant research in order to establish expectations and normative data. Other children should

be wait-listed until more is known.

Finally, strong evidence of family support for any candidate was determined to be a prime consideration. Some objective indicators that identify strong family support include: acceptance of the child's hearing loss, awareness of the child's hearing status and the child's hearing aid needs, and the existence of an effective communication system for the child and his family. In addition, family expectations should be realistic.

Most colloquium committees favored the use of standardized pre-and post-evaluation procedures. Three committees dealt with standardized test materials and made specific recommendations: consistent data collection, pre-surgical training of the child, extended post-surgical training, and the use of an oral training approach with standardized materials.

Participants suggested that the success of a cochlear implantation is influenced by three major factors: the age at which profound deafness occurred, the duration of deafness prior to implantation, and the type of educational program in which the child was placed prior to having implant surgery. The best candidates, that is, those who will perform the best on test measures with a cochlear implant, are children who lost their hearing after the development of speech and language, whose deafness is of short duration, and who are enrolled in an oral/auditory type of training program. Children at the other end of the continuum are those with congenital deafness who are enrolled in a total communication program. Colloquium participants stressed that these criteria should only serve as a guideline for professional teams who wish to evaluate a child's potential success. In general, the consensus of the colloquium was that early intervention provides a better prognosis for success with a cochlear implant and for the acquisition of speech and language skills.

The surgical-medical team considered the risks of cochlear implant surgery in children and the possibility of major side effects, and determined that the risks were minor and were no greater than for adults. Possible contraindications for children receiving multichannel cochlear implants include cochlear abnormalities, such as complete calcification, fibrosis, or congenital malformations. There were numerous comments about the role of otitis media in implanted children, and it was pointed out that, unless a child had severe recurrent otitis media, such pathology has not proven to be a significant detrimental factor to date. Because of significant differences in the electrode designs of cochlear implants, surgeons should undergo special training in the use of the device they select.

The committee on research and design weighed the relative merits of group studies

with matched control counterparts against single-subject control designs. The general consensus was that matched groups are very limiting and difficult to achieve even on a national basis because of the complexity of the variables involved for matching as well as the changing development of children over time. Thus, the committee recommended single-subject designs. Multi-center corroboration of results was considered both valuable and necessary to generate large data bases, with emphasis on data relating to speech perception.

In order to collect data, a national speech evaluation center was suggested. Speech tapes of pre- and post-implanted children could be sent to such a center and

analyzed by objective means and scored on the basis of computer-based speech analysis, automated analysis of suprasegmental sounds, objective analysis of phonology, analysis of linguistics, and other considerations related to measurement of intelligibility.

The multi-disciplinary discussions and debates at the colloquium resulted in a series of position papers which will be appearing in the September, 1986 monograph of *Seminars in Hearing*.

EFFECTS OF DELTA(t) ON THE "BI" POTENTIAL OF THE ABR

Jacob J.M. Semela
Ernest J. Moore
Brad S. Rakerd
Michigan State University
East Lansing, Michigan
Ayalur K. Ananthanarayan
Mercy Hospital
Chicago, Illinois

The human cochlea was investigated using a forward masking paradigm. Positive signal part S(N) of the ABR of 0.82 msec latency and of 70 nV can be identified. The peak occurs before Wave I, hence, "BI". A tone-on-tone forward masking paradigm repeated R times along the dimensions of Delta(t) reveals decreasing Delta(t) values. The BI values, thus, follow an essentially parallel course comparable to a peripheral neural process.

THE EFFECTS OF TINNITUS ON ABR MEASURES

C.L. Ikner
A.H. Hassen
West Virginia School of
Osteopathic Medicine
Lewisburg, West Virginia

The Auditory Brainstem Responses (ABR) of tinnitus patients differ morphologically from nontinnitus patients; the tinnitus ABR's are reported to have "increased" latencies which have not been statistically defined. In this study ABR latencies of tinnitus and nontinnitus patients were analyzed to determine if, (1) the ABR can be used to objectively identify tinnitus patients and, (2) the ABR can be used to monitor the efficacy of tinnitus treatment by observing latency shifts from tinnitus to nontinnitus "norms".

To control the effect of cochlear hearing loss, gender and age in the ABR latencies, the nontinnitus (n=33) and tinnitus (n=33) groups were matched for gender, age (20-55 years), and balanced for equal numbers of normal hearing and cochlear hearing loss subjects with comparable contralateral acoustic reflex thresholds at 1000 Hz, 2000 Hz, and 4000 Hz.

ABR data collected with a Nicolet CA 1000 and Compact IV clinical averagers was compared using Students' Unpaired t-test. The absolute latencies (msec) of tinnitus (T) patients were significantly longer than nontinnitus (NT) patients (Wave I: T=1.88 ± .02 msec; NT=1.76 ± .02 msec; Wave III: T=3.93 ± .03 msec; NT=3.84 ± .03 msec; Wave V: T=5.94 ± .03; NT=5.79 ± .04 msec), all values Mean ± S.E. The III-V interwave interval was significantly prolonged (T=2.01; NT=1.94) in the tinnitus group.

Comparisons between the latencies of males and females within each group

yielded significant latency differences only in the nontinnitus group:

	Wave I (msec)	Wave III (msec)	Wave V (msec)
Nontinnitus			
Male	1.83±.19	3.93±.17	5.96±.24
Female	1.69±.15	3.74±.17	5.63±.22
	p < .01	p < .01	p < .01

Tinnitus			
Male	1.86±.18	3.96±.28	6.00±.23
Female	1.90±.18	3.90±.20	5.85±.22
	ns	ns	ns

These data indicate that because of the prolonged latencies of tinnitus patients differential diagnosis of patients using ABR latency must be done with caution.

A NON-INVASIVE SYSTEM FOR CLINICAL ELECTROCOCHLEOGRAPHY

David J. Lilly
F. Owen Black
Susan M. Doucette
Billie S. Wortham
Good Samaritan Hospital and
Medical Center
Portland, Oregon

For almost two decades, electrocochleography (ECoG) measurements have held great promise for clinical audiometry. These early auditory-evoked potentials provide information about: 1) the amplitude of the D-C summing potential (SP), 2) the A-C cochlear microphonic (CM), and 3) the whole-nerve action potential (AP). Measurement of the AP can be especially useful for frequency-specific evaluation of auditory sensitivity, for estimating auditory tuning curves, and for replicating with human subjects a spectrum of experiments that originally were performed on animals. Comparison of SP and AP amplitude can be useful in the differential diagnosis of endolymphatic hydrops.

Unfortunately, the bulk of ECoG data and norms have been generated by investigators abroad using invasive (trans-tympanic) electrodes. The primary, commercial non-invasive (ear canal) electrode (Coats, 1974) is difficult and time-consuming to use. It has been judged painful by more than 60% of our patients.

This presentation will introduce a new system for generation of clinical ECoG waveforms. Specifically, our stimulus signals are transduced by a shielded, commercial, remote earphone unit (Etymotic Research TubePhone, Model ER3A) connected by its integral tubing to an aluminum coupler that was custom-designed to accept a foam ear canal electrode with a concentric sound tube (Axonics, 3M). This

Abstracts

(Continued from Page 4)

system has been used for ECoG measurements on one ear of 30 subjects with hearing normal for their age and no evidence of inner ear disease. It also has been used for ECoG measurements on 100 patients with a variety of inner ear disorders.

Following a description of the combined transducer and electrode system, we shall compare its frequency and transient response with that of a standard audiometric earphone. We also shall contrast the amplitude of ABR Wave I (AP) produced by this system relative to a standard earphone. Next, we shall compare ECoG data obtained with this system to those obtained using the traditional (trans-tympanic) electrode and the Coats (ear canal) electrode. Finally, we shall summarize amplitude and latency data for the SP and AP measured on normals and on our population of patients with inner ear disease.

INTRAOPERATIVE FACIAL ELECTROMYOGRAPHY: MECHANICAL AND ELECTRICAL RESPONSES

Paul Kileny
Jack Kartush
Constance Spak

Ann Arbor, Michigan

One of the most distressing complications of acoustic neuroma surgery is facial nerve paralysis. The loss of facial nerve function brings about disabling functional as well as emotionally destabilizing cosmetic consequences. In spite of neurotological surgical procedures designed to maximize the likelihood of the correct identification of the facial nerve, the appearance of the course of the facial nerve can be greatly distorted by the tumor. Early monitoring methods relied on the observation of the patient's face by an assistant whose responsibility was to alert the surgeon of facial twitching. More recent versions of this monitoring technique involved photo-electric and mechanical devices that indicated facial movements. One of the drawbacks of these techniques was that relatively vigorous manipulation of the facial nerve was needed to trigger a warning. Recent advances in electrophysiology have brought about the introduction of facial nerve electroneurography (electromyography) into the operating room. The purpose of this presentation is to share our experience in intraoperative electroneurography. In addition to the standard slides, this presentation will be accompanied by a brief videotape presentation that will illustrate intraoperative manipulations and corresponding activation patterns of the facial nerve.

The electronic (EMG) activity is recorded differentially with two subcutaneous needle electrodes placed at the forehead in the midline and the naso-labial fold ipsilateral to the operative site. A ground electrode is introduced contralaterally in front of the tragus. We found that with this montage we can monitor both ipsilateral facial nerve activation as well as contralateral ABR if desired. Facial EMG monitoring usually begins upon opening the internal auditory canal or posterior fossa dura. The EMG output is monitored continuously on the oscilloscope of the evoked potential instrumentation as well as acoustically via a built-in loudspeaker. We are interested in both "mechanical" stimulation as well as responses evoked by intracranial electrical stimulation. We have learned to correlate specific activation patterns related to various intraoperative events such as irrigation and suction,

mechanical stimulation during tumor dissection in the vicinity of the nerve and electrical stimulation using a bipolar constant current stimulator. As a rule, the surgeon is warned at the onset of response activation due to mechanical stimulation, indicating proximity to the facial nerve. This event is usually followed by intracranial electrical stimulation in an attempt to map the course of the facial nerve.

BINAURAL COCHLEAR IMPLANTS: AUDIOLOGICAL RESULTS

Laurie S. Eisenberg
House Ear Institute
Evelyn Gong
Otolitic Medical Group, Inc.
Los Angeles, California

This report presents audiological data on one patient using binaural cochlear implants. She had used a 3M/House single-electrode implant in one ear for five years and a Nucleus multichannel implant in the other ear for three months.

Audiological tests included warble-tone thresholds and live-voice testing of speech tracking, consonant and vowel confusion studies, and AB phoneme identification. Recorded discrimination tests included the Monosyllable-Trochee-Spondee (MTS) test, HEI Environmental Sounds test, the Minimal Auditory Capabilities (MAC) battery, and the Speech Pattern Contrast (SPAC) test. Each device was tested separately with this battery. Binaural testing was done only for consonant and vowel confusions, AB phonemes, speech tracking, and the SPAC.

Comparisons between each implant alone and both together revealed better scores with the Nucleus implant for the majority of tests. Binaural results were better than the Nucleus-only results for speech tracking and consonant confusions in the auditory-visual condition, and the auditory-only presentation of open-set phoneme recognition on the SPAC test.

We will be gathering data on a second patient with binaural implants who has been using a 3M/House for five years and who has just received the Nucleus device.

RESULTS OF CLINICAL TRIALS WITH MULTIPLE COCHLEAR IMPLANT SYSTEMS

Ian M. Windmill, Serge A. Martinez,
Michael B. Nolph, and Barbara A.
Eisenmenger

University of Louisville
Louisville, Kentucky

Investigations comparing the efficacy of various cochlear implant systems have focused on post-implant comparisons of auditory perceptual skills. While these studies demonstrate gross relative strengths and weaknesses of the devices under test, they are constrained by inherent subject differences that include age, length and etiology of deafness, and perhaps most importantly, residual neural population. Additionally, environmental aspects such as program procedures and protocols or business and political decisions regarding subject selection further serve to influence the results of these investigations. The cochlear implant clinical trials program at the University of Louisville has provided several unique opportunities to evaluate various implant systems unconstrained by these variables. First, the program has been approved to implant two multi-channel systems: the Symbion 4-channel device and the Nucleus 22-channel device. This permits comparison of strengths and weaknesses of the complete implant systems, including pre-implant procedures, surgical considerations, post-surgical protocols, and patient results. To date seven patients have received the Symbion system and, three patients, the Nucleus implant. Second, two

patients had single channel implant systems replaced with one of each of these multi-channel systems respectively. This has allowed direct intra-subject comparisons of auditory skills between single and multi-channel devices. Additionally, one of these subjects has experienced three speech processing schemes: 1) the single channel implant, 2) the Nucleus F0/F1 format, and 3) the Nucleus F0/F1/F2 format.

The purpose of this presentation will be to report the results of our experiences with two multi-channel implant systems and to offer insight into the relative merits of each system. Further, the surgical and audiological results of two patients receiving multi-channel cochlear implants as replacements for single channel implants will be reported. The single patient comparison of speech processing schemes will also be presented.

COMPARATIVE RESULTS OF SPEECH DISCRIMINATION TESTING IN QUIET AND NOISE USING TWO FEATURE EXTRACTION CODING STRATEGIES FOR A MULTICHANNEL COCHLEAR IMPLANT

R.C. Dowell
A.M. Brown
P.J. Blamey
G.M. Clark

University of Melbourne
Melbourne, Australia

J.F. Patrick
P.M. Seligman
Cochlear Pty. Ltd.
Sydney, Australia
D.J. Mecklenburg
J.A. Brimacombe
Cochlear Corporation
Englewood, Colorado

The speech discrimination scores obtained from two groups of Nucleus multichannel cochlear implant recipients using different feature extraction coding strategies (F0/F2 and F0/F1/F2) were compared. Both coding strategies extracted the fundamental frequency, second formant frequency, and overall amplitude of the acoustic signal to deliver rate, place, and amount of electrical stimulation, respectively. Additionally, one of the strategies extracted the first formant frequency from the acoustic signal, with its corresponding amplitude, to choose a second more apical electrode for stimulation. The two groups of subjects were administered the Minimal Auditory Capabilities (MAC) battery and a vowel and consonant recognition task. Additionally, word per minute scores for continuous discourse speech tracking were obtained in two conditions (speechreading only and speechreading plus one of the two coding strategies). A smaller group of subjects were given the Four-Choice Spondee subtest of the MAC battery at several different signal-to-noise ratios (SNR = +10, +5) and presentation levels (60, 70, and 80 dBA) to determine the effect of noise on speech discrimination. Results revealed that in quiet and noise the subjects using the F0/F1/F2 coding strategy performed significantly better on almost all measures, with the exception of the easiest prosodic subtests of the MAC battery where ceiling effects were evident. In quiet, the largest improvements were obtained on the open-set subtests of the MAC battery with scores for spondee recognition of 13.6% for F0/F2 and 26.0% for F0/F1/F2; CID sentences = 15.9% for F0/F2 and 35.4% for F0/F1/F2; and monosyllabic words = 4.9% for F0/F2 and 12.4% for F0/F1/F2. In noise, at a +10 SNR, performance on the Four-Choice Spondee subtest was minimally degraded using the F0/F1/F2 coding strategy. These results were compared to those obtained by Gantz, Tyler, McCabe, et al, 1985, which showed significant degradation on the same task with the F0/F2 coding

strategy. These preliminary results show that the addition of the first formant in a feature extraction coding strategy provided improvement in speech discrimination both in quiet and in noise for profoundly deafened individuals using a multichannel cochlear implant.

AUDIOLOGICAL EVALUATION WITH A NEW IMPLANTABLE HEARING DEVICE: THE XOMED-AUDIANT

Robert M. Johnson
Oregon Health Sciences University
Portland, Oregon

Jack Hough
Tom Himelick
Merle Phillips
Central Ear Research Institute
Oklahoma City, Oklahoma
Sharon Graham
Ear, Nose and Throat Clinic
Little Rock, Arkansas

Inherent problems associated with present-day bone conduction hearing aids have greatly limited their use. Yet, there is a definite need for a means of supplying amplification with good fidelity to patients with conductive hearing losses who cannot benefit from otologic surgery or conventional hearing aids. In an effort to provide better amplification to patients with external or middle ear pathologies, a new implantable hearing device has been designed and developed by two research groups, the Central Ear Research Institute in Oklahoma City and the Kresge Hearing Research Laboratory in Portland, Oregon, in conjunction with the Xomed Corporation in Jacksonville, Florida. This device, referred to as the Xomed-Audiant, utilizes an inductive coil to transmit bone-conducted sound directly to the cochlea.

The Xomed-Audiant consists of a small samarium cobalt magnet that is implanted subcutaneously in the temporal bone, an external coil wound around a second magnet, and a speech processor with a microphone to activate the coil. The external inductive coil is held firmly in place behind the patient's ear through the use of the two magnets. The coil produces an electromagnetic field that causes the internal magnet to vibrate. This vibrational pattern provides direct stimulation of both cochleae through the bone conduction pathways.

This device was initially implanted in one of the authors (RJ) who has normal hearing bilaterally, and the results were positive. To date, the device has been implanted in twenty patients with conductive hearing losses at three facilities in Oklahoma City; Portland, Oregon; and Little Rock, Arkansas. The initial results with these patients have been encouraging. Two generations of processors, both body units, have been evaluated and presently a behind-the-ear device is being developed.

Experimental data on these initial twenty patients will be discussed and compared to results obtained with conventional air conduction hearing aids and a bone conduction hearing aid.

INSERTION GAIN, HEARING AID PRESCRIPTION, AND INTELLIGIBILITY AMPLIFIED SPEECH

Chaslav V. Pavlovic
Ruth A. Bentler
University of Iowa
Iowa City, Iowa

Insertion gain measurements provide the means of accurately controlling the signal delivered to the hearing-impaired listener. The advantage over the functional gain measurements is that the effects of changes in hearing aid parameters can quickly and accurately be measured. The estimate of these effects requires only a passive participation of the patient. This potential ease of controlling the effects of

(Continued on Page 6)

Abstracts

(Continued from Page 5)

various adjustments should be matched by an equally flexible clinical evaluation tool. This tool should: (1) be simple enough so that the effects of various adjustments of the hearing aid's controls can be rapidly assessed; (2) provide adequate information to the clinician in regard to the effects of these adjustments on the spectrum of the amplified speech; (3) provide for rapid and simple calculation of the predicted speech intelligibility; (4) be adequate for patients who can make various judgments of the delivered signals (e.g. LDL measurements) as well as those who cannot.

We present in this paper a complete hearing aid prescription and evaluation strategy that satisfy these requirements. The paper is divided into five parts. In the first part we present an analysis of the everyday speech spectrum and suggest the values across frequency that best characterize it (speech peaks and speech minima as opposed to the long term average). Next, we derive the HTL of these parameters. This enables us to use an ordinary audiogram for both calculating and visualizing the effects of a hearing aid.

The second part of the paper deals with the amplification goals. We discuss various approaches used for this and suggest a procedure close to the one used by Cox (1983). We position the average speech peaks between the LDL level (the level that is too loud to be listened to for any period of time) and the threshold. The LDL levels in the ear canal are either determined by direct subject's judgments or by a formula if the subject is not able to give these judgments.

The third part of the paper deals with procedures of preselecting the aid based on the manufacturer's specification and our targets. Both a simple approximative procedure for a noncomputerized clinic as well as a more accurate procedure to be used in computerized facilities will be briefly discussed.

In the fourth part of the paper a clinically acceptable articulation index procedure will be explained. Its accuracy, interpretation and applications will be discussed. The relationship between the AI and the acceptability of the aid will be examined.

In the final part of the paper we will discuss our clinical experiences with the procedure.

VARIABILITY OF PROBE MICROPHONE MEASUREMENTS OF THE EAR CANAL

Allison Coleman

John Sedey

Otologic Medical Group, Inc., and
House Ear Institute
Los Angeles, California

The increasing interest in the use of ear canal probe tube microphone test systems for objective measurement of hearing aid gain is widespread. The professional literature to date has focused on the design rationale and advantages of this measurement approach, comparability of probe tube to canal microphone devices, effects of sound source azimuth, probe insertion depth, effect of room acoustics, and reliability in an anechoic chamber. There are also some reports indicating that these measurement systems have been useful for individuals in the clinical practice of fitting hearing aids.

Numerous questions remain unanswered about this measurement approach. When looking at these systems for possible clinical use, even the casual observer will note that measuring the same ear twice will often yield different curves. Additionally, some test systems measure with the probe in one ear ref-

erenced to the opposite ear. This assumes that there is no difference in resonant characteristics between ears on the same subject. Beyond the variability of measurements made on an individual subject, we had questions about the range of differences in external ear canal resonance effects across a number of individuals. Do they vary greatly, minimizing the clinical usefulness of median values?

The goal of this investigation was to look at the variability of ear canal measurements using a probe tube microphone system. Test/retest was performed on both ears of forty subjects, right ears were compared to left ears for each subject, and variability was examined across all subjects. The magnitude of variability is sufficiently large in some instances that the use of single-sweep unfiltered probe measurements, tests referenced to the contralateral ear, or tests using corrections for an "average" canal effect, should be viewed conservatively.

LOUDNESS DISCOMFORT LEVELS IN CHILDREN

Mary E. Kawell

Judy G. Hemenway

Patricia G. Stelmachowicz
Boys Town National Institute
for Communication Disorders
in Children
Omaha, Nebraska

Loudness discomfort levels (LDL's) traditionally have been used to set the saturation sound pressure level (SSPL) or maximum output of a hearing aid. Theoretically, these measures ensure that signals do not reach levels of intolerance for the aided listener. Since coupler measures (2-cm³ or Zwislocki) of SSPL90 do not adequately reflect levels developed in the ear canal, they must be used in conjunction with LDL's obtained for individual hearing aid users. Recently, Hawkins et al. (1985) described a procedure whereby SSPL90 2-cm³ coupler values corresponding to aided LDL's can be obtained. Preliminary data suggested that the procedure is both reliable and valid when used with adults.

Although it is believed that real-ear SPL values in children may be substantially higher than in adults, systematic and predictable differences could not be demonstrated by Nelson et al. (1986). However, they suggested that real-ear measures are necessary to define the SSPL90 of a hearing aid accurately. Although such measures do define the SSPL90 of a hearing aid more accurately, they do not ensure that the upper limit of tolerance has not been exceeded. To date, no systematic study has been conducted to determine if LDL's could be obtained in children. LDL procedures commonly used with adults are inappropriate for children due to the complexity of the listening task. In the absence of an LDL, the output of a child's hearing aid is typically set based on coupler or real-ear measures of SSPL90.

The present study measures LDL's on hearing-impaired children using a modification of the procedure described by Hawkins, et al. Data will be presented on the repeatability and validity of the procedure for children 7 to 14 years old. The LDL data obtained from this age group will be compared to similar data from hearing-impaired adults. Suggested 2-cm³ coupler values for SSPL90, derived from LDL measures as a function of frequency and hearing level, will be presented. It is anticipated that these values could be used as general guidelines for setting SSPL90 in children for whom empirical measures of LDL are not possible.

FIDELITY VS. AMPLIFICATION

Michael F. Seidemann

Eye, Ear, Nose & Throat Hospital
Roger P. Juneau

General Hearing Instruments
New Orleans, Louisiana

Electronic and acoustic advances in hearing instruments in the past few years

have provided clinicians with the ability to fit an expanding spectrum of the hearing impaired population.

Frequently, patients with hearing loss limited to the frequencies above 1500 Hz are not considered to be candidates for amplification. However, the introduction of the canal configuration of in-the-ear instruments (in-the-helix instruments) has changed our thinking as well as clinical approach to these patients.

This group of patients typically presents with a series of subtle symptoms of hearing loss by subjective report. Acoustic sensitivity is not often expressed as a primary complaint. Rather, these patients are extremely analytic relative to their acoustic difficulties and they describe indicators of more pronounced hearing loss. The patients usually complain of discrimination difficulties in poor listening conditions as well as a great deal of physical and emotional "strain" during occupational communicative situations. Most of these patients are involved in professional type occupations which require intense concentration and communicative accuracy.

The in-the-helix instruments in conjunction with a great deal of counseling have produced excellent patient acceptance and considerable improvement in subjective perceptions of hearing problems by our patients.

This paper will focus upon a compilation of patient data as well as details of the electronic and acoustic aspects of open canal ITE fittings. Counseling approaches for this group of patients will also be presented.

ACUSTIC AND PERCEIVED BENEFIT FROM PERSONAL ASSISTIVE LISTENING DEVICES

Margaret A. Wyld

Institute for Technology
Development

Florence E. Davenport
University of Mississippi
Oxford, Mississippi

A wide variety of personal assistive listening devices (PALD's) are available, yet we have not established routine recommendation of the devices to our clients because of the lack of information relative to the utility, desirability, and evaluation of PALD's. Additionally, the lack of standards to govern the construction of ALD's and the absence of regulations to enforce the provision of electroacoustic specifications for the devices further compounds the difficulty of knowing which device to recommend. The study completed by the authors has identified the acoustic and perceived qualitative benefit provided by several devices.

Thirty consecutive volunteers were solicited from clients receiving audiologic services at the Speech and Hearing Center. They satisfied the following criteria:

1. Pure tone average >25 dB HL <60 dB HL;
2. Age 45 to 75 years; and
3. Sensorineural loss of hearing sensitivity.

Each subject was evaluated with six different personal assistive listening devices. The order of presentation of the devices and the order of the evaluation measures were counterbalanced among subjects to avoid fatigue and order effects. The same device (supplied by the manufacturer) was used with all subjects. An electroacoustic analysis of the output of each device was completed at regular intervals during the course of the study to track variations in signal output.

The paper will present the results of the following measures completed with each subject without the use of the PALD and with each of the PALD's: Qualitative judgment of music and discourse in quiet and in noise (+6 dBS/N ratio) using a modification of the Adjective Rating Scale of Gabriellson and Sjorgren (1975); measures of the insertion gain; estimates of the identification of speech stimuli using the

California Consonant Test (Owens Schubert, 1976) in quiet and in noise, and an estimate of the perceived benefit of PALD's. The study was completed in a sound-treated test room with tape recorded test signals presented through a loudspeaker located at a distance of six feet from the subjects. Remote microphones were located at a distance of one foot from the loudspeaker transducing the test signals.

ACUTE AND LONGTERM AUDITORY DEFICITS IN SEVERELY BURNED CHILDREN TREATED WITH OTOTOXIC DRUGS

James W. Hall III

University of Texas Medical School
Houston, Texas

Cindy Gary

University of Texas Medical Branch
Galveston, Texas

James B. Winkler

David N. Herndon

Shriners Burns Institute
Galveston, Texas

The burn population often requires potentially ototoxic drugs in treatment of infection. Cochlear damage may be a unfortunate consequence of this life-saving medical therapy. Prediction of ototoxicity in the acute burn patient is extremely difficult as there are numerous factors that may influence the risk of cochlear damage. Yet, prompt identification and aggressive management of hearing impairment is especially important for burned children. The objectives of this investigation were: 1) to assess the usefulness of the auditory brainstem response (ABR) in early detection of auditory deficit in a pediatric population during the acute period following a severe burn, 2) to correlate ABR findings with physiologic parameters, drug profiles and hospital course and 3) to describe the longer term auditory deficits resulting from ototoxic medical therapy.

Over 250 separate ABR assessments were carried out for a series of 75 children (aged 3 months to 17 years) with greater than 40 total body surface area burned (mean 65%). None of the patients had a known history of hearing impairment or aminoglycoside therapy. All ABR testing was completed at bedside in an intensive care unit with commercially-available equipment. Drug data and details of the patients' hospital course were abstracted from medical records. Serial follow-up behavioral audiometry within the first year after hospital discharge was performed for over 75% of the survivors.

All patients yielded a normal ABR at baseline intensity levels down to 40 dB at the baseline assessment immediately after hospital admission. Upon final ABR assessment before discharge, however, one-out-of-ten patients had an absent or abnormal ABR at this intensity level. None showed brainstem transmission time abnormalities. Followup audiometry revealed pure tone hearing loss for 20% of the series. Fifteen patients with ABR evidence of auditory deficit were matched on the basis of percentage of burn with 15 patients with a normal ABR at discharge and normal followup audiometric findings. Although each group received multiple potentially ototoxic drugs (gentamicin, amikacin, vancomycin, amphotericin B, lasix), there were significant differences between groups in dosage and duration of medical therapy. Complex interactions were found among drug profiles and characteristics of hospital course (eg length of stay), which confounded the prediction of ototoxicity in individual patients.

The ABR test protocol used in the acute period, and the audiometric configuration revealed in followup testing, are of particular interest to the clinical audiologist. Delayed onset and progression of sensor-

(Continued on Page 7)

Abstracts

(Continued from Page 6)

neural impairment after discontinuance of ototoxic drugs was documented with pure tone, immittance and speech audiometry. Drug-related auditory impairment was characterized by unusually poor speech understanding. We conclude that the audiologist can play an important role in the acute and longterm management of severely burned children.

CLINICAL USE OF THE AUDITORY BEHAVIOR INDEX IN INFANTS:

A CAUTIONARY NOTE

Thomas E. Borton

University of Alabama

Birmingham, Alabama

William A. Cooper, Jr. &

Pamela L. W. Halligan

University of South Carolina

Columbia, South Carolina

The Auditory Behavior Index (ABI) developed by Northern and Downs (1978) as a model for estimating auditory threshold in infants is useful, but has limitations: it is based on behavioral observation audiometry (BOA) techniques; there is substantial response variability at each age level; and the methods used to collect the data are not reported. Although Northern and Downs cautioned clinicians to use the ABI only as a model, experience suggests that the Index is often used inappropriately in clinical settings. In this paper, we discuss the effects of methodology on hearing threshold estimates in infants, present data emphasizing some limitations of the ABI, and suggest some appropriate uses of this instrument.

METHODS

Audiometric data were obtained from a total of 16 normal infants ranging in age from 7 to 13 months, using speech and FM pure-tone stimuli. A visual reinforcement audiometry (VRA) paradigm was utilized under typical audiometric test conditions. The subject/observer room arrangement is presented in the paper.

RESULTS AND DISCUSSION

The audiometric findings were similar to those of Wilson and Moore (1978) for infants of similar age. Direct comparison of these data with those of Northern and Downs is difficult (their data were reported in hearing threshold levels, their warbled-tone frequencies are unknown, etc.). In general, however, threshold data for speech and pure-tone stimuli were nearly 30dB more sensitive than predicted by the ABI. Abuses of the ABI fall into three major categories, and these are discussed with reference to the present findings. We support the use of the ABI as a model but discourage its indiscriminate clinical use in profiling absolute hearing sensitivity in infants. The importance of methodological considerations in the interpretation of infant audiometric data for diagnostic as well as (re)habilitative planning is detailed.

CENTRAL AUDITORY PROCESSING DISORDER: DIAGNOSIS AND INTERVENTION

Louise H. Loiselle

Brad A. Stach

James F. Jerger

The Methodist Hospital and

Baylor College of Medicine,

Houston, Texas

Critics of the concept of central auditory processing disorder (CAPD) in children characteristically cite two major problems. First, opponents of the specifically auditory nature of the disorder cite a lack of "hard" evidence to support the diagnosis and often conclude that this lack of evidence denies the reality of the problem. Second, identification of CAPD has often been considered irrelevant due to the lack of a rational intervention strategy. In the present paper, we address these two issues based on our recent experience with a comprehensive identification strategy and

with intervention based primarily on enhancement of the auditory figure/ground relation.

Fourteen children, ranging in age from 3 to 12 years, were identified as having CAPD. Diagnosis was based on a test battery including pure-tone, immittance, speech, and auditory evoked potential audiometry. Speech audiometry included use of the Synthetic Sentence Identification (SSI) test or the Pediatric Speech Intelligibility (PSI) test. Auditory evoked potential audiometry included measurement of early latency (ABR), middle latency (MLR), and late V (LVR) responses.

Results showed an array of abnormalities. Of the 11 children from whom auditory evoked potentials were carried out, all had normal ABR's. However, 8 had abnormal MLR's and 7 had abnormal LVR's. Only 1 of the 11 children showed normal evoked potentials across the entire array of measures. Speech audiometry was abnormal in all but 2 of 13 children. All children showed abnormal results on speech audiometry, evoked potential audiometry, or both.

Since the major symptom of these children and complaints from their parents were inattentiveness and distractibility in difficult listening situations, rehabilitative management was directed toward improvement in signal-to-noise ratio (S/N). Intervention consisted of either the use of a personal FM assistive listening device, or classroom and household strategies for improving S/N ratio. As a result of these intervention strategies, both parents and teachers reported marked improvement in the children's performance.

Case studies will be presented showing that "hard" evidence of CAPD can be provided through a comprehensive audiological evaluation and that intervention to improve auditory figure/ground can be successful.

THE INFLUENCE OF CONCENTRATION ON VESTIBULAR INDUCED NYSTAGMIC ACTIVITY

Robert I. Davis

Plattsburgh State University College

Richard Mann

SUNY

Plattsburgh, New York

This study examined the effects of four mental alerting tasks on the slow phase velocity (SPV) and beat frequency (BF) of caloric-induced nystagmic activity to determine the effect of each task (i.e. concentration) on the degree of nystagmic suppression release. Forty subjects were randomly divided into four groups (10/group) and stimulated four times (2/ear) in a counterbalancing order according to test ear, stimulating temperature (30° and 44°C) and alerting task.

Nystagmic activity was induced by a closed loop caloric system (150cc/min) and monitored for 60 seconds following stimulation. Each of the two active participation tasks (AT-mathematical calculations and reflexive questioning) and two passive listening tasks (PT-classical music and a story) were presented separately for 60 seconds following stimulation with an eight minute rest interval employed between stimulations.

Results demonstrated a greater SPV composite mean value for the "mathematical calculations" (21.4°) followed in order by the "reflexive questioning" (19.9°), "story" (15.3°) and "music" (10.0°) task conditions. Approximately 65% of the subjects exposed to the AT stimulations yielded a greater average SPV than the same subjects did to the PT's. In addition, stimulations yielding mean SPV's of 5° and less occurred in 37.5% of the PT's and in only 2.5% of the AT's. Comparisons of the composite mean BF data also showed a decrease as the degree of concentrated effort decreased from an active to a more passive mental state (e.g. mathematical calculations (12.1), reflexive questioning (10.9), story (9.3) and music (8.6).

Analysis of variance and post hoc testing revealed that the AT's and PT's differed significantly with respect to both SPV and BF activity.

Our results suggest that the use of passive listening tasks result in a significant suppression of induced nystagmic activity which make them inadequate as alerting stimuli. We suggest that either one of the active participation tasks utilized in this study adequately controls the alertness factor and the subsequent release from nystagmic suppression during clinical electronystagmography testing.

BOBBING OSCILOPSIA AS A RESULT OF GENTAMICIN INDUCED VESTIBULAR TOXICITY

Patricia J. Webber

William E. Davis

James W. Thelin

University of Missouri

Columbia, Missouri

When the peripheral vestibular mechanisms are disabled or destroyed bilaterally, there is a disruption of sensory input to the cerebellum, the vestibulo-vegetative reflex arc, and the vestibulo-ocular reflex arc. The effects are loss of information to control muscles for body orientation, absence of nausea with changes in head position, and a shifting visual image of the environment with head movement. As a result, it is difficult to walk even with support, and rapid motion of visual images has a completely disorienting effect. The most prominent patient complaint with this condition is the illusion of movement of the horizon when walking. This phenomenon is called bobbing oscillopsia.

We are reporting on two cases of bobbing oscillopsia due to gentamicin ototoxicity (Case 1, 61 year old female; Case 2, 41 year old male). Both were treated for bacterial endocarditis with gentamicin. In the literature on gentamicin ototoxicity, the auditory system is affected less frequently than the vestibular system, and the vestibular damage is usually irreversible.

For both patients, the first complaints were of whirling vertigo, nausea, and vomiting 30 days after the initiation of gentamicin therapy. Neither complained of decreased hearing. From that time forward, the patients were monitored with electronystagmography and audiometry. Two days later the vertigo was replaced by bobbing oscillopsia.

In Case 1, the bobbing oscillopsia was markedly reduced after 5 months. Recovery of vestibular function was documented with the emergence of caloric responses bilaterally. Hearing remained stable throughout this time period.

In Case 2, there were no measurable caloric responses at 8 months and no recovery from bobbing oscillopsia at 19 months after the onset of the problem. The patient continues to use a walker. He is still disoriented by surroundings with complex patterns and is unable to look at the horizon when riding in an automobile. We will present a videotape illustrating his difficulties standing and walking. For this patient, there may have been some loss of hearing and slight recovery.

GLYCERIN TEST: METHOD FOR ANALYSIS OF PURE TONE THRESHOLD SHIFTS

William H. Slattery

Jack M. Snyder

University of Washington

Seattle, Washington

James W. Thelin

University of Missouri

Columbia, Missouri

A variety of pure tone threshold shift criteria have been used with the glycerin test. Typically, the investigators who recommended a particular method have not provided a rationale for using the method to the exclusion of other methods. We developed a rationale for selecting a shift criterion and used the rationale to develop a new method for specifying the

significance of threshold shifts in the glycerin test.

The experimental data were results from one author's (J.M.S.) first 173 glycerin test patients. The mean data indicated that glycerin systematically improves hearing at 250, 500, 1000, and 2000 Hz and has no significant effect at 4000 and 8000 Hz for Meniere's ears. For non-Meniere's ears, glycerin worsens the hearing slightly at 500 Hz and has no significant effect at other frequencies.

The method we used to measure threshold shift was the average shift at 250, 500, 1000, and 2000 Hz. A shift of 6.25 or more was considered significant (p < .01 based on non-Meniere's ears). This method includes sensitive frequencies, excludes non-contributory frequencies, and reduces variability with averaging. The method is capable of detecting small changes for ears with nearly normal hearing and for Meniere's ears that are nearly "burnt out." The method requires no special equipment, signals, or procedures.

We compared our method to other methods and found it to be slightly better than the second best method (15dB shift at any one frequency). For our method, the specificity was 1.00 and the sensitivity was 0.56. It is clear from our data that this test is not appropriate to diagnose Meniere's disease. It does, however, appear to separate reactive Meniere's ears from all others. The identification of the Meniere's reactive ear may be important in its own right.

RELATIONS BETWEEN PSYCHOPHYSICAL TUNING CURVES AND AGE, WORD RECOGNITION SCORES, AND DEGREE OF HEARING LOSS

Lisa Hunter Smolak

Gary P. Jacobson

Laura W. Kretschmer

The purpose of this study was to investigate relationships between frequency resolution as measured by Psychophysical Tuning Curves (PTC's) and age, degree of hearing loss, and word recognition scores for three groups of subjects. Fourteen elderly subjects with mild to moderately severe sloping sensorineural hearing loss, seven elderly subjects with normal hearing, and ten young subjects with normal hearing were used. The means and ranges of pure tone thresholds for the 3 groups are presented.

Psychophysical tuning curves were analyzed digitally for Q (10) and tip-to-tail distance. A simultaneous tone-on-tone sweep-frequency masking method (McDonald, 1983) which was subject-controlled was used to obtain PTC's. PTC's were measured at 500 and 2000 Hz, at both equal sensation levels, and equal sound pressure levels for all subjects.

Correlation coefficients were determined for relationships between frequency resolution data and maximum word recognition score in quiet (PB Max.), frequency resolution data and age, frequency resolution data and degree of hearing loss.

The results indicated that PB Max. was not significantly related to frequency resolution data. This finding is consistent with previous literature, which has not uncovered any consistent relation between word recognition scores measured in quiet and frequency resolution ability. A significant, negative relationship at the same frequency was found. This finding is consistent with that reported by Pick, Evans, and Wilson (1977) and suggests that frequency resolution of the peripheral auditory system may be affected by degree of hearing loss. A significant negative relationship was also found between frequency resolution ability and age. A conclusion of loss of frequency resolution as a function of age is premature, however. Differences in performance due to age on the psychophysical task required to measure frequency resolution must be investigated before such a conclusion may be reached.

Marion Downs and Jerry Northern enjoying her tribute.

Tribute to AAS Member

The famous Brown Palace Hotel in Denver, Colorado, was the scene of a fabulous gala fund raising event in tribute to Marion Downs. Attended by more than one hundred friends and associates, the Gala was the kick-off for the National Symposium on Hearing in Infants held September 25-26, 1986, honoring Marion Downs for her pioneering work in the early identification of hearing loss in children. All proceeds from the National Symposium were presented to the Marion Downs Children's Hearing Fund, and a check for \$10,000 was presented in her behalf at the Gala Tribute party.

During the Gala Tribute, a plaque was unveiled with the names of eighteen individual benefactors who contributed substantially to the Marion P. Downs Children's Hearing Fund. The plaque will be permanently mounted in the Otolaryngology-Audiology Clinic of University Hospital at the University of Colorado Health Sciences Center. The award cites Marion Downs as an outstanding clinician, teacher, and advocate.

The University of Colorado Health Sciences Center is collecting donations which will be put into endowment in appreciation for the excellent contributions of Marion Downs and her lifetime efforts on behalf of children with hearing impairment. The name of Marion Downs is, of course, synonymous with pediatric audiology, and the purpose of the endowment fund is to award an annual Pediatric Audiology Fellowship to a practicing audiologist who desires additional specialty training and research opportunity in some aspect of pediatric audiology.

During her outstanding career at the University of Colorado Health Sciences Center, Mar-

ion Downs pioneered, developed, and evaluated techniques for testing hearing in children. She is noted internationally for her work in the area of early identification of hearing loss and in infant hearing screening. Her publications and teaching have brought worldwide attention to the importance of early habilitation for deafness, and have alerted the medical world to the developmental problems associated with childhood deafness.

Mrs. Downs is an excellent teacher and prolific writer; no student of hearing disorders has passed through course work without being profoundly influenced by her. Thousands of patients, especially grateful for her concern and wisdom, have benefitted from her devoted effort to better their lives.

Dr. Downs is recognized as an important educator, clinician, author, and progressive advocate for the hearing-impaired. Her professional colleagues have honored her with numerous awards; among them are the Outstanding Achievement Award of the University of Minnesota, the Gold Medal from the University of Colorado, an Honorary Doctorate of Human Services from the University of Northern Colorado, the Honors of the American Speech-Language-Hearing Association, and the Service Recognition Award of the American Medical Association.

To date, nearly \$50,000 has been generated for the Marion Downs Children's Hearing Clinic on the way to a projected goal of \$300,000. All donations are tax exempt and may be sent to the University of Colorado Foundation, Campus Box A065, 4200 East Ninth Avenue, Denver, CO 80262.

Aural Rehabilitation Forum

Panel Discussion - Hearing Health Care for the Elderly

Editor's Note: This panel discussion represents the third article in a series of three that kicked off our Aural Rehabilitation Forum. These papers composed the proceedings of a conference on aural rehabilitation held in 1983 in Winter Park, Colorado. The discussion that follows was organized under the direction of Ronald L. Schow, with the general theme of AR concerns for aging adults.

Panel discussion members included Schow, moderator (Idaho State University), and Thayne Smedley (Nu Ear Electronics), along with the following: Miriam Henoeh (North Texas State University), Katherine Gerkin (Audiotone), John Cooper (University of Texas Health Science Center, San Antonio), Robert McLaughlin (Central Michigan University), Victor Garwood (University of Southern California), Robert Traynor (Colorado State University and private practice), Elmer Owens (University of California Medical Center), and Laura Wilber (Northwestern University). While all those participating in the discussion are audiologists, they represent a wide range of experiences and viewpoints. Some do and some do not dispense hearing aids. Some work for the hearing aid industry, while others work in university or private practice settings.

Panel Discussion

Ron Schow: I'd like to ask first for Miriam and Katherine to offer any responses that they may have at this point.

Miriam Henoeh: First I want to respond to the Art Linkletter thing. I agree that somehow or another audiologists, if we are to promote ourselves as better providers of hear-

ing health care than some other groups, have to become more visible. But, I'm not convinced that the approach that was discussed, a promotional approach, is the best way to go. Promotional techniques are to me questionable, especially if those who respond to the promotion are not treated ethically, which I have witnessed in my area.

Ron Schow: Dr. Smedley do you want to comment on that?

Thayne Smedley: Yes, if I were you, I would be just as concerned. I feel strongly that one reason there is room for audiologists in hearing aid promotions is because the right people aren't necessarily providing the follow-up. This letter does a good job in getting people into the office but some dealers have less than a completely ethical orientation, and this can be a problem. If a dispenser is primarily bent on selling numbers, without looking at the quality of the product, or the fitting, or the quality of the follow-up, then it represents abuse of a system that is effective in getting people in. The manufacturers might argue that there is apt to be some falling by the wayside, but if you get a hundred people in and lose five or ten, that's better than the ninety successful users who wouldn't have been reached with an ineffective method. The best combination is an effective tool for reaching hearing aid candidates, and responsible, qualified persons doing the fitting and follow-up. This is where the dispensing audiologists can get involved.

Ron Schow: Miriam, I'm wondering how you would feel about an audiologist lining up with this kind of a promotion?

Miriam Henoeh: Well, it's hard for me to even think like that because I come from an Ivory Tower background. So it's very difficult for

Over 230 Attend 1986 Annual Meeting

The 13th annual meeting of the American Auditory Society was held November 20, 1986, in Detroit, Michigan, prior to the American Speech-Language-Hearing Association meeting. Members of the Program Committee and its Chairman, Bill Rintelmann, are to be congratulated for a job well done! The meeting was the perfect blend of stimulating papers, outstanding professional interchange, and great fun!

More than 230 participants, representing the disciplines of audiology, otolaryngology, otology, research, and hearing and speech science, took part in this year's meeting. All in attendance agreed that this was one of the Society's best annual meetings ever!!

The one-day meeting, held in cooperation with Wayne State University School of Medicine and Children's Hospital of Michigan, assembled a faculty of presenters involved with state-of-the-art procedures and research. The topics of electro-physiologic measures, implantable hearing devices, amplification and rehabilitation, pediatrics, and vestibular testing filled the day's agenda. Each paper offered information critical to contemporary clinical perspectives.

The highlight of every AAS meeting is the

Carhart Memorial Lecture. This tradition is presented each year by an outstanding member, whose career has been distinguished by contributions to the field of human hearing. This year's Carhart Memorial Lecturer was Dr. Joseph E. Hawkins. His presentation, entitled "Traces of Age in the Ear and the Eye," is available on videotape.

A new feature of this year's program was the availability of continuing education credits from three different sources, illustrating the diversity of the disciplines that make up the Society. This year's meeting was accredited for continuing education units by the American Medical Association, ASHA, and the National Hearing Aid Society. Thanks goes to Deborah Hayes of the AAS Executive Committee for making this possible.

Special events in this year's meeting included presentation of the Beltone Distinguished Audiology Teacher of the Year award to Roger Kasten. Recognition was given by the Editors of *Ear and Hearing* to the authors of three outstanding articles in Volume 6 of this journal. A very special presentation was made to Susanne Kos, Assistant Secretary of the Society. Presi-

**Dear AAS Members
and Corti's readers,**

Share

You will be interested to hear that SHARE (Speech and Hearing Alliance for Resource Exchange) is making progress. I first introduced SHARE to AAS members at the 1985 annual meeting, and provided some updated information in the last issue of *Corti's Organ*. Individuals who are not familiar with the purposes of SHARE can find a description elsewhere in this issue of *Corti's Organ*. During the past 12 months we have received donations of many text books and journals. We have provided four different programs with materials, including the Speech Pathology and Audiology program at the Catholic University and the Department of Otolaryngology at the Escola Paulista de Medicina in Sao Paulo, Brazil; and to the Charles University Post-Graduate Medical Institute in Prague, Czechoslovakia. In addition, we have provided Dr. Aruegodore (John) Oyiborhoro of Port Harcourt University, Port Harcourt, Nigeria with 15 years of JSRR, JSHD, DSH Abstracts, and 40 or so text books. John will use those materials to help start up an Audiology training program at his university. I can assure you that individuals who have received materials are grateful for your contributions.

At the recent ASHA convention I met with the executive board of the National Student Speech Language Hearing Association (NSSLHA) to ask their support of SHARE. It appears that they will include SHARE as one of their service projects in the coming year. We will get more information from NSSLHA in the near future and communicate with AAS members through the next *Corti's Organ*. NSSLHA's help with SHARE is deeply appreciated.

In the meantime we are continuing to solicit text books in Audiology, Speech Pathology, Otolaryngology, and related fields. We would also appreciate some journals. It would be best to write and let me know what you have to donate before sending them on. Any cash donations that can be used to offset shipping costs are equally welcome. Finally, if you know of any training program or professional group in countries where resources and finances are limited that would benefit from SHARE materials please let me know.

From The Editor

As my first year as Editor for *Corti's Organ* comes to a close, I can't help but reflect on the changes that have taken place in my life since I accepted this "prestigious" post. I have learned what galley proofs are; how to compute column length; how to paste-up; and — how to beg. The begging part came easy.

With each issue of *Corti's*, it has been necessary for the Editorial Board to actively recruit papers and articles for inclusion. Rather than preach or beg for material to be printed, I'll simply remind you of subject areas that need your attention and input. Consider submitting to the Clinical Section (case studies, assessment overviews, etc.); the Equipment Review Section; the Aural Rehabilitation Forum; the Name That Lesion Column; the Audiology/AAS Trivia Column; or the Special Edition, "*Corti's* 10th Anniversary."

Now, if none of those spark your typewriter, I

have a new idea to get those creative juices flowing. A new column will be added to *Corti's Organ* that will allow you to "get it off your chest." The "What's Bugging You?" column can serve as your soap box. Do you have a pet issue, philosophy or concern that you want to discuss? Send it to *Corti's*. Controversies such as live voice vs. taped presentations for speech audiometry always prompt discussion. I'm sure each of you has his own thoughts on this issue as well as on others.

The Editorial Board would like to thank all who have assisted with articles over the past year. We couldn't have done it without you. And thanks also, in advance, to those who are now inspired to submit.

Virginia Berry
Editor

The President's Corner

Editor's Note: From time to time this special feature, contributed by the AAS President, will appear in *Corti's Organ*.

**Prelinguistic Deafness
vs. Prelingual Deafness**

Back when I was a resident, "congenital deafness" was used to describe children born deaf or hard of hearing. We soon learned that some babies had normal hearing at birth, followed by rapid degeneration of hearing before speech began. In an attempt to coin a term that encompassed both of these terms, "prelingual deafness" came into use. It is a semantic disaster. "Prelingual" does not appear in *Dorland's Illustrated Medical Dictionary* or in *Webster's New World Dictionary*. It does appear in the *Oxford Dictionary*, but it is an anomaly.

"Prelingual" is, in fact, a non-word, but if it were a word, it might mean "in front of the tongue," or "before the tongue (was formed)." This is nonsense as applied to hearing loss. However, Northern and Downs, in their first edition of *Hearing in Children*, refer to "auditory behavior as prelinguistic behavior." I quote

from that section: "The invariable presence of the babbling responses in both the deaf and the hearing infant seems to us to represent reflexive, pre-adaptive behavior unique to the human infant.... Its importance in the prelinguistic sequence of activities may be that it reinforces vocalizations by means of rewards.... The beginnings of language learning occur at birth and — who knows? — possibly before birth."

I urge members of the AAS to consider using the term "prelinguistic" deafness or hearing loss. Down with "prelingual"!

Over 230 Attend

Continued from Page 1

Dent Worthington surprised Susanne with a plaque, given as a tribute to all her years of service and dedication to AAS. Bill Rintelmann, 1986 Program Chair, and his Program Committee also received well-deserved recognition. (Members of this committee are listed elsewhere on this page. LaVonne Bergstrom, President for the coming term, presented outgoing chief, Don Worthington, with a plaque honoring his years of leadership.

The evening's entertainment planned by local arrangement liaisons, Frances Eldis and Sabina Schwan, was the biggest treat! Dinner and show were enjoyed by all at Mykonos Supper Club in Detroit's Greek Town. The food was exceptional, but as may be seen in the picture included in this issue, the entertainment was second to none. The night was the perfect conclusion to a full day!

Next year's meeting will be held in conjunction with AAO in Chicago. Lazlo Stein, Program Chair, has already begun his plans to insure that 1987's meeting is another hard act to follow. Bill Rintelmann and the 1986 Program Committee have made 1986's conference just that. See you in Chicago.

1986 AAS Meeting Available on Video Tape

The entire proceedings of the 1986 convention of the American Auditory Society are now available on video tape. The video tape is approximately six hours in duration. It includes the Carhart Memorial Lecture by Dr. Joseph Hawkins entitled:

"TRACES OF AGE IN THE EAR AND THE EYE"

This year the video tape is accompanied by a complete set of documents representing the visual aids used by the presenters. The video tape is available in VHS format only. The cost is \$35.00. Please allow 4-6 weeks for delivery.

Please make check payable to:

AMERICAN AUDITORY SOCIETY

Send order to:

Michael F. Seidemann, Ph.D.
Joachim Hearing & Speech Center
Eye, Ear, Nose & Throat Hospital
145 Elk Place
New Orleans, LA 70112

The video tape should be sent to:

1986 Editors' Awards Announced

Each year, the *Ear and Hearing* Editorial Board acknowledges outstanding contributions to this publication through the presentation of the Editors' Award. The purpose of this award is to recognize manuscripts that exemplify the standard of quality that the *Ear and Hearing* Editorial Board strives to achieve.

Manuscripts were selected on the basis of these criteria:

- the interest and timeliness of the research question.
- the appropriateness of the research design and methodology
- the appropriateness of the analysis
- the clarity of the writing
- the appropriateness to the purpose of the journal

Selection of the three most outstanding articles in a volume of *Ear and Hearing* is not easy, as there were many worthy papers among the

60 published. Nevertheless we were able to choose three articles which admirably represent the standards we wish to maintain.

In order of their appearance in the journal, the three articles chosen as outstanding contributions for Volume 6, 1986, are:

The Crib-O-Gram in the NICU: An Evaluation Based on Brain Stem Electric Response Audiometry; Andree Durieux-Smith, Terence Picton, Christopher Edwards, John T. Goodman, and Brock MacMurray; Vol. 6, No. 1.

Cochlear Summating Potential to Broadband Clicks Detected from the Human External Auditory Meatus: A Study of Subjects with Normal Hearing for Age; Gian-Emilio Chatrian, Adelina L. Wirch, Kyoko H. Edwards; Giorgio S. Turella, Mark A. Kaufman, and Jack M. Snyder; Vol. 6, No. 3.

Hearing Loss in the Elderly: An Epidemio-

logic Study of the Framingham Heart Study Cohort; Eve K. Moscicki, Earleen F. Elkins, Herbert M. Baum, and Patricia M. McNamara; Vol. 6, No. 4.

The awards were presented at this year's annual AAS meeting in Detroit. Plaques were given to the authors, honoring their significant contributions.

President Worthington makes presentation to Carhart speaker, Joseph E. Hawkins.

Eve Moscicki accepts award.

Rintelmann receives acknowledgement.

Fran Eldis accepts certificate of appreciation for local Arrangements Committee.

Editors' Award granted to Andree Durieux-Smith.

Corti's editors looking for news.

Bob Keith presents Editors' Award.

Society honors Susanne Kos.

Local Arrangements Committee - still smiling!

19th International Congress Scheduled

The International Society of Audiology will hold its 19th INTERNATIONAL CONGRESS OF AUDIOLOGY in Jerusalem, Israel, June 5-9, 1988. Topics of the Round Tables are: Hearing Dysfunction Associated with Systemic Diseases, Methods for Evaluation of Benefits of Hearing Aids, and Auditory Deprivation from Middle Ear Disease (in children). Free paper sessions on a variety of topics in audiology will be held throughout the four-day congress. For further information please contact: 19th International Congress of Audiology, P.O. Box 50006, Tel-Aviv 61500, Israel.

Continued from Page 1

me to say "stick an audiologist in there, and that makes it ethical." I have former students who have now gone into dispensing hearing aids. I have friends who are audiologists that have gone into dispensing hearing aids. If you start looking at their sales practices versus the hearing aid dealer sales practices, you begin to see that there's not much difference. By putting an audiologist in that system, I don't know that that's going to satisfy me as to the ethical approach to dispensing hearing aids that is violated by this kind of promotion.

Ron Schow: I agree with you. One of my concerns is that I see audiologists going out saying "Well, it would be nice to have a little extra money; let's sell some hearing aids." And they do. Then next year they've changed jobs, or they've moved to another university

and they've put their shingle out to sell hearing aids there. What happened to their clients to whom they have an ethical responsibility in the place where they formerly practiced. I believe audiologists are coming into these ethical problems maybe in a little different way, but they are, and we in training programs have an obligation to begin raising their consciousness, their awareness of their ethical responsibilities. But, at the same time, if we have promotional techniques that can be linked with good, appropriate follow-through, that seems to me perhaps to be the best of both worlds.

John Cooper: You know, there is a mentality that says "more is better, and hustle-hustle-hustle; and let's all go out and sell jewelry, or cosmetics, and get a pink Cadillac." Detroit and the auto industry used that craziness, if

I may call it that, and Detroit is in deep trouble. For a concrete example, the Japanese came over here and had a decent product, and people bought Japanese cars because they were really better. And macho ads of a Ford Mustang racing along down the road are not going to help Ford products. What'll help Ford products is an automobile that stays together, was fit properly to begin with. I have some real problems with numbers for their own sake. I think the people who are bent on that, in the long run, will be in deep trouble.

Thayne Smedley: That, I think, is a good statement, and it reflects your orientation. However, if you were president of some hearing aid corporation, the matter of numbers would be a critical issue.

John Cooper: That's not so, and the Japanese have proved it, and Detroit lost their hide on it.

Ron Schow: But, you see, the quality brought the numbers. It's just a different way of going after the numbers.

Thayne Smedley: That, I think, is a good statement, and it reflects your orientation. Granted they must have the quality, but they are tied very closely together. If you get involved in retailing, get involved in the hearing aid industry, the mentality may be crazy, but it reflects the fact that what they eat and what they wear and what they drive, and how they house themselves are

all tied to income. And if they don't make the income, they don't have a certain standard of living. Sales units and money are tied just that closely. We're very much aware that hearing aid offices are first businesses, and if they don't succeed businesswise, they can't think of helping the hard-of-hearing. But, if you're in a university setting where your income isn't necessarily determined by the growth of the product you turn out, sitting in some other office where it's not tied directly to sales, then it's easier to think in a more broad context of rehabilitation and quality as opposed to quantity. It's a major conflict, and I honestly don't know how you get around that.

Ron Schow: I apologize in a way for bringing the numbers up. But, I heard Gwen Vaughn the other day talk about 900 letters from persons who need help with assistive listening devices and saying that they weighed on her conscience. It seems to me that we have some appropriate concerns in aural rehabilitation about small groups of people: the multiply handicapped, the blind hearing impaired, for example, and the cochlear implant group, the elderly in nursing homes. And while I wholeheartedly support our concern with these small individual groups, I'm amazed that we don't have the seven million elderly hearing impaired out there.

See Aural Rehabilitation, Page 3

Executive Committee at Work and Play

The 1986 Executive Committee had their work cut out for them as they attempted to "beat the clock" and address 20 agenda items in a record four hours. As veteran committee members know, their hard day's efforts are rewarded by a splendid evening of wining and dining. This year was no exception. (Proceedings of the Executive Committee meeting are included so that you can be aware of the work

accomplished.)

The evening at the Lands Down Restaurant on the Detroit River began with a delightful array of tempting hors d'oeuvres and cocktails. A fine dinner followed, complete with prime rib, wine, and a sparkling view of Canada. The entire evening was just the relaxation needed by the Executive Committee after a long and productive day.

weighing on our conscience. It seems to me that there is a big group that we ought to be doing something about, and I don't hear us talking about that very much.

John Cooper: The issue is not if they're there. The issue is what is the best, long-term strategy for attracting them. And hustling them, I submit, is going to burn this group of audiologists and eventually this group of hearing aid manufacturers.

Katherin Gerkin: To address the whole point of professional ethics and dispensing, some may say it's a dilemma. Really, I don't think it's a dilemma. I don't see that. I think it's very naive of you to think that you don't deal with numbers from a manufacturing point of view. My company does not promote sales in the way that Thayne's company does; but the bottom line is that we certainly look at numbers. If we didn't sell hearing aids we wouldn't be in business. I think to get these people in we need public awareness, but I don't think we do a very good job of that. You look around and you see spots for hearing impaired people on television or whatever. First maybe they can't hear them, and if it doesn't hurt the person you're not going to get them in. I don't care how many of those hearing impaired elderly people are out there, if it doesn't in some way impinge upon their functioning, it's not going to get them in.

Other things come into play, whether we like it or not. Things like in-the-ear hearing aids. Those are the aids that draw people from a marketing standpoint. When you see ads for eyeglasses do they tell you how great they're going to correct your vision? No, they tell you how sexy and wonderful and beautiful you're going to look. These are not things that I as an audiologist like to look at,

but certainly as a marketing or manufacturing representative you have to look at it. Now, once you get that person in, certainly as a professional you fit him the best way that you can. But, I think what Ron Schow is concerned about is how you get the awareness out to the people.

Ron Schow: The question of ethics, it seems to me, does not really hinge on whether you advertise or don't. It's how you advertise, and it's how you follow through. And to John and those who feel as he does, I would say "What is unethical about advertising?" It's interesting to me to look and see that audiologists are now advertising just as much in phone directories as the hearing aid dispensers are. Five years ago we were not. It may be that we can stand back on our principles and say we won't go after those seven million people, but I am saying to you, because of our principles that require us to help the hearing impaired, we ought to be concerned and trying to do something about the plight of these people. And maybe promotion of this sort, followed with good, responsible, audiological help is what we need.

Bob McLauchlin: Two issues came up today that I'd like to address. First of all, I'd like to preface my remarks by saying I'm a strong advocate of audiologists who are involved in dispensing hearing aids. By dispensing I mean purchasing aids from manufacturers and selling them to clients. By selling I mean something more than just hanging them on ears. The first issue is offering free audiological service in promotional advertising; and the other issue is tying audiologists to selling a single manufacturer's hearing aid. I feel very strongly as an audiologist, in terms of the Justice Department's deci-

sion in relation to fair practices, that manufacturers should concentrate on promotions which would not minimize the services provided by audiologists. I think that the provision of free services isn't consistent with our principles. I would like to see manufacturers moving in the direction of promoting the need for amplification, referral for professional services, and a de-emphasis on high-pressure sales.

The second issue that has existed for many years is the concept of a dealer selling a single manufacturer's aids. As you know, the Justice Department said a long time ago that manufacturers can't own the dealers. The dealer is an independent practicing business person who can sell any product he or she wants to sell. Obviously, manufacturers are going to try to sell their own products. I think that when audiologists sell for a single manufacturer, it does pose some real problems in terms of how they make decisions for their clients, and raises ethical problems. So I would urge manufacturers who understandably attempt to sell their aids through dispensing audiologists to be sensitive to these two issues.

Thayne Smedley: I would like to respond to that. I agree with both points. However, the latter point is not a problem throughout the country. In my experience there is virtually no dispensing office now that feels committed particularly to any one manufacturer.

Victor Garwood: I certainly agree with John's remarks about quality and so on, but the present number of hearing aids being used is nothing but a drop in the bucket compared with all of these millions of people who are not getting hearing aids. What will happen to the cost of hearing aids for the consumer public if we go high volume and

reach greater numbers of the hard of hearing? Will the price go down?

Thayne Smedley: I think all of us here are aware that the manufacturing costs of hearing aids have gradually crept up, but substantially.

Victor Garwood: No, I mean the economic has been going down, hasn't it?

Thayne Smedley: That's correct, and a lot of the people we work with say how come are more expensive this year than last year because things are more stable and the economy of some things is reversing like real estate and so on. The thing that makes the business viable is the bottom line on profit and loss statement. And he is going to be selling hearing aids cheaper next year than he did last year. The manufacturing cost may actually ease up, although a significant reduction is not likely. Further, since the actual wholesale cost of a hearing aid represents a relatively small proportion of the retail cost of the aid, I don't anticipate that if the volume picks up, the price will be reduced. Let me cite an example. You are aware that you can buy hearing aids at various levels, at different prices, and so retailers will sell them at a different price. I am aware of a dispenser who sells hearing aids for \$269.00, and he advertises them regularly. Those who compete against him don't know how he can stay in business. It happens to know he doesn't depend entirely on his hearing aid business to support his family. One of his competitors approached him as a member of the industry with this question: "How do I combat that? I'm selling them \$495.00, and how do I combat him \$269.00?" You'd be amazed at the answer.

"Raise your price \$100.00." And that's exactly what he did. The philosophy being, my product and my service is worth every dime that I charge. If you want to charge half the price, that must indicate what you think yours is worth. The public tends to respond to the kind of thinking, whether it's right or wrong.

The whole matter of the pricing structure of hearing aids has always been a curious thing to me. When I was with the VA I was aware of what the government paid for hearing aids, and it used to grate on me considerably when I heard what they were charging downtown. I don't feel that way about it now. I believe quite strongly like a friend of mine who dispenses hearing aids and has for 25 years. I asked him, "What do you charge for your hearing aids?" I charge \$600.00, period." This was about a year ago. I said, "It seems a little high. Don't you think that's excessive? Why do your people pay it?" He said, "They pay it for one reason: I look them right in the eye and I say, I am worth \$600.00. You're not buying a piece of plastic with electronics. You're buying services, you're buying me for as long as you use the hearing aid, and I will be there when you need help." If that means driving two or three hours from where he lives to give this client service, that's what he does. He feels like he's worth it.

In answer to your question, I don't think the price is going down, I think it's going to be commensurate generally, with the cost of living, and will continue to move up proportionately.

Ron Schow: I think that's what several have been saying, that people need to charge appropriately for their services.

Thayne Smedley: The price of hearing aids is a very tough issue. There is a segment of our population that cannot afford better hearing because of the price. We need to make a provision for them. But, there is another major segment of senior citizens who have expendable cash, and the price of hearing aids doesn't seem to bother them. To cite an example, I was involved in a promotion in a small community recently; we promoted the sale of 24 hearing aids at a total cost of something like \$14,000.00 I collected \$12,000.00 of that amount up front! The money's right there.

Bob Traynor: I just want to respond to a couple of things. As to the idea of someone going out and selling hearing aids and leaving: I think that's a bit far fetched, simply because most audiologists don't do that. I have had somewhat of a schizophrenic orientation towards the field for about five years now, sitting under one hat at the university, and then the other hat in private practice in the late afternoon and evenings, and Saturdays and summers. The interesting part of that is if I were to leave, I would sell my practice as a physician would sell a family practice or as another type of dealer would sell a business of some kind. I think most of us who deal in this way would tend to do that, and very much consider our clients who are out there using our devices, who have paid us their fees, and so on.

Another concern is, I also think that we as a group deal from two extreme ends of a continuum. In other words, we have one side with the manufacturers telling us that we have to promote, promote, promote, selling numbers, numbers, numbers, and then we have our own conscience based on our training and so on that says, "Oh, you can't do that, you have to be ethical and professional, and all these things. As I see it, we're training our students with one side of this, and they go out in the world and find they're way on this side. What's really coming out of this is something in between. The way I make it in my practice is not high visibility promotional materials, but I do use quite a bit of print media with a professional announcement type ad. I also do columns in things like *The Senior Voice*, which is paper for marketing things for senior citizens. I see us moving toward this, but until we get to the point where there are more of us living in the real world and living in the academic world at the same time, we're not going to have the kind of experience that's necessary to train students to live in a private practice situation.

Elmer Owens: To get back to Miriam, it seems

to me that as audiologists we are not practicing our right to making a good living. Our clinic is always in the red. Audiologists are out of work. I'm wondering what your actual communication is with those dealers in town who are making more than you are. You're doing all the work, and you're doing the follow-up, and you're listening to all these grievance. I can see that the wave of the future that Thayne has described so well is coming. How can we work together in the marketplace and still provide professional experience. I'm wondering how you go about it in your small town?

Miriam Henoeh: I wish I could answer your question. I wish there was a way that we could do something like you are alluding to. When I first came to Denton about five years ago there was only one other dealer there. I make an effort to work with dealers in a number of ways. For example, in terms of referrals. Also, possibly sending students to them for practicum experience. But I could not continue to do that because this dealer wanted me to refer all the patients that we see for hearing aid evaluations back to him. I would not do that. So, communication between us broke down. I really don't know how to bridge the gap.

Katherine Gerkin: After having gone into it from industry's side of the profession, I see more and more audiologists who want to go out and dispense; and their biggest thing is to undercut the dealer in price. I always sit back in amazement when they've said, "I'm professional, and I have a master's degree or a Ph.D. degree, and I'm better, and I'm going to do a better job. So I'm going to charge less!" It's always such a dilemma to me. If we are willing to offer patients better service, better fittings, rehabilitation, why are we cutting our throats? What is wrong with making a dollar as an audiologist? I just have problems with that.

Miriam Henoeh: I don't think there is anything wrong with that.

Ron Schow: I'd like to report something Thayne told me that is really interesting. The complaints we hear often depend on what office we're sitting in. We as audiologists have been sitting in the audiology offices and having the unhappy clients come in and complain about what's been happening to them in the hearing aid dealer's office. But the reverse is true also, and we just haven't been hearing the other side of it.

Katherine Gerkin: There are good dealers and bad dealers. There are good audiologists and bad audiologists.

Thayne Smedley: I worked recently with an audiologist who wears two hats: he does some clinical testing, but primarily he dispenses hearing aids. The comment he made to me was, and I hear it a lot, "the biggest problem I have as a dispenser is working with naive audiologists who don't know straight up about amplification systems. And some of the biggest fiascos are those that are recommended by the university audiologists." I think this statement relates a little bit to Ron's comment earlier that sometimes we can abuse the power we may have as audiologists if we really attract the people because of some professional image, but lack the specific skills to properly fit the aids. We may say that we think this client should have "thus and so," but perhaps we haven't had the experience with different instruments that may be available at the moment, or with filters and dremel tools, and all of the physical and acoustic modifications that the dealer has learned to use over 10 or 15 years of experience. The successful dealer really does help hearing problems, and he does it very well; if didn't he would not continue to be successful. The word gets around very rapidly.

I would like to make a further comment about cost. If the hard-of-hearing person would be more inclined to step forward, say, like the visually impaired, the price of aids could be cheaper. It's a real quandary to me why people with hearing loss behave so differently from those with visual problems. The visually impaired are not nearly so promoted and exploited. They seem to go and take care of their problems. The hearing impaired, for a variety of reasons, do not. If they would step forward, the cost of hearing aids would easily be one-third less because

we would not be involved in the great advertising and promotional schemes which are expensive. But having said that, it doesn't change the matter. We can sit back in our office and say we're the professionals. We need to get these people coming in, but they don't come, and they get picked up in the mainstream of these other people who promote.

One final comment related to John's concern about "promoters." I was in a western community not too long ago, a town of 12 to 14 thousand people near two larger metropolitan areas; there were five traditional dealers in that town, and, incidentally, no audiologists. I asked one lady who came in response to our invitation, "How many times does the mail bring some advertisement about hearing aids?" She said "once or twice a month." I asked her what she did with those ads. She said, "I just throw them away." Did you ever study them? "No, I hardly ever read them." I asked why she didn't do that with the Linkletter letter. I was curious. "Well," she said, "I really don't know why, it's just after you get hit so many times you feel like, well, maybe this is the time." Some people in the hearing aid industry say there is a five year lapse between the time a person becomes aware of a hearing problem and the time he does something about it, and that in the meantime, they have received some twelve different advertising impressions. These are tendencies in human behavior we have to deal with.

Laura Wilbur: A couple of things. One, we started dispensing at Northwestern, and one of the reasons we did, was so we could hang on to our clients. We realized for years that people who were unhappy with their hearing aids do not come back to our clinic no matter how many free services we gave them. We always told them that they could

have a free clinic visit after they got their hearing aids and all those wonderful things. It didn't work. If we think of it, we can understand why they never come back. They went to the hearing aid dispensers. So we started dispensing. We've been with it less than two years, and we've learned a great deal about hearing aids. Number one, we're fitting more in-the-ear aids than we thought we ever would, because we found the elderly had less trouble manipulating them. And they don't like behind-the-ears, which doesn't make any logical sense to me. But it's the truth. The second thing we found out is that we do charge, and we charge an equivalent price to our local dispensers, which shocked them because they were sure we were out to put them all out of business. The reason we charge more for the product is that we put a dispenser fee on it, and put it out front. We say "This is what we're charging for our dispensing fee, and we charge that to you because we're good, and we know what we're doing. We're also going to give you additional services, and we have rehabilitation possibilities, and some counseling." They don't seem to complain. The only time we've had a problem was recently when a patient said, "Look, this is going to cost us \$350, and I was told by an audiologist who came out to our senior citizen's center that we should never pay more than \$300 for a hearing aid." So we did ourselves in. We have not promoted, because we get all kinds of referrals coming in, but we have no problem with the idea of promotion. The problem is what's said in direct mailing. If the thing that's said is true, I see no problem with direct mailing. I think it's the wording and what follow-up services we can provide afterward; that's really the issue, and we have to individually, ethically deal with it.

Ron Schow: I thank you all very much for your comments.

Richard Thomas accepts BHI Achievement Award from Executive Director, Joe Rizzo.

Richard Thomas Honored for Hearing Information Efforts

Better Hearing Institute has presented its 1986 Better Hearing Achievement Award to actor Richard Thomas for his "outstanding public education efforts on behalf of Americans with hearing problems."

The award was presented by BHI executive director, Joe Rizzo, who said: "Richard Thomas' efforts for the cause of better hearing have been extraordinary and much appreciated by those who serve people with hearing loss. His television and magazine public service messages have been especially effective in spreading encouragement about available hearing help."

Thomas corrects his own hearing loss with canal hearing aids. Magazines donating space to his BHI public service advertisement in 1986 included *Time*, *People*, *Family Circle*, *U.S. News and World Report*, *Money*, and *New York*. His television public service announcement for BHI has been granted generous time by hundreds of stations promoted by the Delta Zeta Sorority, a national sorority with 121,000 members committed to better hearing. Thomas

recently joined other famous Americans in the latest edition of BHI's *We Overcame Hearing Loss* celebrity booklet, made possible by a Delta Zeta grant.

Thomas, known to many for his Emmy Award-winning role as "John Boy" in the popular television series, "The Waltons," will lead the Council for Better Hearing and Speech Month's 1987 campaign on behalf of 22 million Americans with communicative disorders. He was elected National Chairman of the May campaign at the consortium's recent annual meeting in Washington, D.C.

Thomas will act as chief media spokesman for the Council's national public information effort. He personally overcame a mild hearing loss caused by cochlear otosclerosis. Thomas will launch the Council campaign during early May kickoff ceremonies in Washington, D.C., where he will release a special message from President Reagan, introduce the 1987 poster child, and make a series of national media appearances.

AAS

MEETING

GREEK TOWN WE

LCOMES SOCIETY

Incoming President LaVonne Bergstrom expresses Society's appreciation to Worthington.

Society Says Thank You to President

Don Worthington, Past-President of AAS, was honored in style at this year's annual meeting held in Detroit in November. For the past two years, Don has given to the Society his time and energy. He has consistently worked "above and beyond the call of duty." As President, Don has led AAS to its highest membership and helped in the development of many new Society projects. The Society has been lucky to have his leadership.

In attempts to show Don how much AAS appreciated his dedication and blood, sweat, and tears, Ross Roeser, Secretary/Treasurer, presented Don with a special award at the conclusion of the annual meeting. This award was certainly a symbol of the Society's gratitude, but the "piece de resistance" was the tribute read by Ross. Entitled "Ode to Worthington," this masterpiece of verse was written by Steve Blum, husband of Susanne Kos. Although not an "official" AAS member, Steve has assisted and supported the Society in various ways.

Just so *Coda's* readers can have the sense of being present at this tribute to Past-President Worthington, the Ode follows. All that's left to say is - Thank you, Don, for a great two years!!!

Retired Hearing Professional Offers "Hearing Loss Basics"

Alec Combs, former owner of Allied Hearing Aid Service of Santa Monica, California, puts his years of experience to good use. Mr. Combs has dealt with hearing health care from both sides. Not only is Mr. Combs a hearing impaired adult who has used amplification for many years, he also has been an active hearing professional serving the needs of this population.

Following these years of experience, Mr. Combs recognized the frustrations of hearing impaired persons and realized that the answer to many problems could be found in educating people. Such education can produce changes in speech and listening skills which can prompt dramatic improvements in relationships troubled by hearing loss.

In his attempts to address the concerns of public education, Mr. Combs has developed a series of pamphlets entitled "Hearing Loss Basics." Each pamphlet presents basic information on selected topics, ranging from signs of beginning hearing loss to communication methods. One primary focus of the series is to develop an effective means of helping those with mild losses whom Mr. Combs feels are often by-passed in today's hearing care system.

The information contained in these pamphlets may be of use to you, the professional, or to your patients. For more information contact: Alec Combs, P.O. Box 1841, Santa Monica, California 93456.

An Ode to Worthington

With candor and, I hope, with tact
I'll tell you this surprising fact:
Don's many gifts to me and you
Relate to things he likes to do.

With rich and tender morsels he
Has nourished our Society.
Perhaps this gastronomic feat
Relates to how Don loves to eat.

Look carefully around this room
And you'll not find a hint of gloom.
This happy state reflects the style
Of Don, a man who likes to smile.

The AAS has moved ahead
With speed and energy. It's said
Our honored president is one
Who stays in shape and likes to run.

With clever steps and grace galore
He's waltzed around the legal floor,
Our chosen causes to advance.
And don't we know — Don loves to dance.

Concerning membership, I've heard
Proliferation is the word.
Again Don's likes come into play:
With all those kids, what can I say?

My premise, which I hope is true,
Is that in serving me and you,
Don's liked his work and had some fun.
We thank you, Doctor Worthington!

— S. Blum

Infant Workshop Scheduled

On March 27, 1987, Lutheran General Hospital, Neonatology Section, will sponsor a medical symposium entitled "Continuing Care of the High Risk Infant." This one-day seminar will cover topics relevant to the total management of the high risk infants. Early intervention strategies, parent involvement, augmentative communication, and orthopedic management are just a few of the areas to be covered. Guest faculty include: T. Berry Brazelton, M.D. of Children's Hospital of Boston; David Yoder, Ph.D. of the University of North Carolina; and Beverly Sills, Chairman of the March of Dimes Media Council.

This conference will certainly offer those in attendance an outstanding educational experience. For additional information contact: Kim Walkup, Newborn ICU office, Lutheran General Hospital, 1775 W. Dempster, Park Ridge, IL 60068, (312) 696-5313.

Speech and Hearing Alliance For Resource Exchange

Share

The primary purpose of SHARE is to assist in the international development of Audiology and Speech/Language Pathology training programs and services through the sharing of surplus textbooks, journals, reprints, or other materials and resources.

A secondary purpose is to share experiences and information among persons with a common interest in helping the communicatively impaired.

The primary recipients of these resources will be training or clinical programs in developing nations which do not have the means to purchase journals and textbooks necessary for the development of professionals, and which will serve the communicatively handicapped in their countries.

Books, journals, and other materials will be obtained through donations from individuals and libraries. Although more recent editions of textbooks are most useful, any edition can provide background information for beginning scholars or serve as a reference for more advanced professionals. In addition, all volumes of professional journals would serve as valuable resources.

The conduit for distributing these materials will be the Communicative Disorders Founda-

tion, a non-profit tax-exempt foundation. The president of this foundation is Donald A. Shumrick, M.D., and the vice president is Robert W. Keith, Ph.D. The Communicative Disorders Foundation has obtained a start-up donation to cover the expense of forwarding materials to recipients. Additional grants and donations will be solicited.

Tax deductible gifts of books, journals, materials, or cash will be acknowledged in writing by the Communication Disorders Foundation. The acknowledgment will contain an itemized listing of books, journals, or materials donated for distribution.

Suitable recipients will be forwarded materials appropriate to their needs. A stipulation of the exchange is that materials will be placed in libraries where they will be generally available to scholars.

Any donations of resources or letters of inquiry should be addressed to:

Robert W. Keith, Ph.D.
Div. of Audiology and Speech Center
Dept. of Otolaryngology

Minutes of the American Auditory Society Executive Committee Meeting

Date: November 19, 1986

Place: The Children's Hospital, Detroit, MI
Time: 1:30 p.m.

Members Present: Virginia Berry, LaVonne Bergstrom, Patrick E. Brookhouser, Alison M. Grimes, Deborah Hayes, Robert W. Keith, Susanne Kos, David J. Lilly, David M. Lipscomb, David Preves, William F. Rintelmann, Ross J. Roeser, Michael F. Seidemann, Wayne J. Staab, Laszlo K. Stein, Don W. Worthington.

Members Absent: F. Owen Black, Richard T. Miyamoto, James J. Pappas.

Guests: Steve Blum, Irvin Gerling, Susan Jerger, Ralph Naunton (Chair, long-range planning), Ken Startt.

1. President Worthington opened the meeting at 1:37 p.m. He thanked the members of the Executive Committee for their attendance and recognized the guests that were present. He then read a memorial to George Lynn, an AAS member of long standing who had recently passed away.
2. The minutes of the 1985 AAS Executive Committee meeting were reviewed and approved.
3. The treasurer's report for the period 1/86 through 10/86 was reviewed by Ross Roeser. The overall financial status of the American Auditory Society was reported to be in excellent condition. Based on this, no increase in dues was recommended.
4. Ross Roeser gave a report on membership. As of 11-1-86, there were 1903 members. This represents 217 more members than in 1985. Of the 1903 members, 1537 (82%) are audiologists, 6 are engineers/industry representatives, 46 (2%) are hearing aid specialists, 192 (10%) are physicians, 28 (1%) are associates, and 58 (3%) are student members.
5. Ross Roeser was appointed as Secretary/Treasurer for 1987/88. President Worthington discussed the Secretary/Treasurer's allowance and indicated that an increase had been requested. He recommended that the compensation be set at \$300.00 per month (\$3,600.00 per year). After discussion a motion was made to increase the Secretary/Treasurer's allowance to this amount beginning in 1987, and the motion was passed.
6. Susanne Kos was appointed as Assistant Secretary/Treasurer for 1987/88.

7. Bill Rintelmann reported on the 1986 meeting. He indicated that the program committee had functioned effectively throughout the year, and all indications were that the 1987 meeting would be well attended. He gave special thanks to Sabina Schwann and Francis Eldis, who served as the local arrangements committee.

8. Laszlo Stein gave a report on the 1987 meeting. He indicated that he has been in contact with the Academy of Otolaryngology-Head and Neck Surgery, and has received a favorable response. Our meeting will be held in either the Hyatt - Chicago or the Marriott - Chicago hotel. The committee members have not been selected, although David Hill has accepted the position as local arrangements chairman.

Considerable discussion was held on how to expand the meeting. Two possibilities included having concurrent sessions and/or extending the meeting beyond one day. In addition, the possibility of having the American Auditory Society meet separately from other organizations was discussed. No specific motions were made, but it was concluded that the members be surveyed informally to attempt to find out their preferences.

President Worthington discussed a letter he had received from Derald E. Brackmann, Chairman of the Hearing and Equilibrium Committee of AAO-HNS. In the letter, Dr. Brackmann discussed the "possibility of a cross-registration for the American Academy of Otolaryngology, the American Auditory Society, and the Association for Research in Otolaryngology (ARO) when the three meet together." This would have the advantage of not requiring an extra registration fee for the members of each group to attend the other two meetings. This was discussed by the board and will be pursued further with both AAO-HNS and ARO. The task of investigating these issues was assigned to the Long Range Planning Committee.

The names of several individuals were discussed as 1988 Carhart speakers. LaVonne Bergstrom, as Chairman of the Nominations Committee, was charged with developing a slate of individuals. At a later point in the meeting four individuals were presented and voted upon. One individual was identified, and Dr. Bergstrom will be in con-

See Executive Committee Minutes, Page 14

International Symposium Exhibits Tennessee Hospitality

International Symposium Huge Success

July 28-30, 1986, marked the Third International Symposium on Childhood Deafness, sponsored by the Bill Wilkerson Hearing and Speech Center and by the Division of Hearing and Speech Sciences, Vanderbilt University School of Medicine. For the last three decades this event has become a landmark in continuing education. Hosted once every ten years, this Symposium brings together a faculty of distinguished speakers in the fields of audiology and deafness.

This year's conference, held in Nashville, dealt with the hearing impaired child and with the etiology, identification, and management of auditory disorders. Presentations on genetics, syndromes that deafen, ototoxic hazards, viral/bacterial agents, and epidemiology of otitis media were among the Symposium's interesting topics. Papers discussing high risk infant assessment, behavioral evaluation techniques, acoustic immittance measurement, cochlear implant evaluation techniques, hearing aids and assistive devices, and neuromaturational considerations in electro-physiologic audiometry each enhanced the conference's exploration of contemporary assessment. Discussions on communication development, cognitive training, psychosocial issues, parent involvement, and language intervention strategies were only some of the topics presented which were related to management of the hearing impaired child.

The Symposium was "kicked-off" with the W.W. Wilkerson Memorial Lecture given by Feature Speaker, Dr. Bettye Caldwell of the University of Arkansas at Little Rock. Dr. Caldwell's papers "You've Come a Long Way, Baby" traced changes that have occurred in the field of early childhood growth and development.

Marion Downs, a professional who needs no introduction, served as the Banquet Speaker. Her presentation, entitled "Stalking the Hearing Guru," was an entertaining, light look at our profession and some of its elite. No description of the impact of this address could do it justice.

The three days in Nashville brought together over 300 participants who left enlightened, inspired, and exhausted. The 3rd International Symposium on Childhood Deafness was the perfect mixture of intellectual stimulation and social interaction, such as only the Bill Wilkerson Hearing and Speech Center and Vanderbilt University can provide. The Symposium was one of this decade's most impressive events and will long be remembered by those who attended. The Planning and Steering Committee is to be congratulated on a job well done!

(The proceedings of the Symposium will be published in text form in the near future. For information on this excellent culmination of papers contact Fred Bess, Director of Bill Wilkerson.)

A Professional Celebration

On July 26, 1986, prior to the start of the 3rd International Symposium on Childhood Deafness, a very special event took place in Nashville. A professional tribute honoring Jay W. Sanders, Ph.D., was sponsored by the Bill Wilkerson Hearing and Speech Center and by Vanderbilt University. In celebration of Dr. Sanders' completion of his 25th year of formidable contributions to diagnostic audiology, a one-day conference was hosted, entitled "Diagnostic Audiology: A Golden Anniversary." This event was a series of lectures focusing on state-of-the-art practices in the field of audiology.

The faculty of notable contributors to our

field, who were both colleagues and friends of Dr. Sanders, presented papers covering such topics as neurodiagnostic audiometry, audiologic manifestations of acoustic tumors, acoustic reflex measurement, central auditory assessment, medical audiology controversies, and many more.

The day was topped off with a gala banquet and tribute to Dr. Sanders. Letters video-taped presentations, and personal commentaries provided the opportunity to honor this respected mentor, colleague, and friend. It was truly a special day for a very special man.

Executive Committee Minutes

Continued from Page 12

- tact with this person to verify his acceptance of the award.
9. Boston was chosen as the site of the 1988 meeting. Frank Musiak was selected as program Chairman for that meeting.
 10. Robert Keith gave a report on *Ear and Hearing*. He indicated that Deborah Hayes was resigning from the Editorial Board, and that Susan Jerger will be her replacement. Based on 1986 figures, he estimated that 100 manuscripts would be submitted to the journal in 1987. The average time for acceptance of manuscripts for the past six years ranged between 4 to 6 months, and the average time

for publication ranged from 9 to 13 months; he indicated that he has encouraged the Editorial Board to review manuscripts as expeditiously as possible, in order to keep the review time within these limits.

The selection process for the editorial award was reviewed. For 1986 (Volume VII) editors will be asked to recommend manuscripts only from the sections they review. This list will then be sent to all Editorial Board members for voting.

Future plans include publication late in 1987 of a supplement on the Vanderbilt symposium. A second supplement will be

guest edited by Dr. Lu Beck on current hearing aid fitting techniques.

Mr. Ken Startt, Vice President for Periodicals at The Williams and Wilkins Co., the publisher of *Ear and Hearing*, reported that there are currently 3500 subscribers to the journal. This represents an increase of 400 subscribers from 1985. He indicated that the profits for 1986 will be approximately \$8,000-10,000. He anticipates that for 1987 the profits will be between \$18,000-20,000. Overall, he indicated that the publisher was pleased with the progress *Ear and Hearing* has made.

The Executive Committee discussed an honorarium for the Editor of *Ear and Hearing*. After discussion, it was agreed that \$1,000.00 per year should be provided, beginning in 1987.

11. Virginia Berry reported on *Corti's Organ*. She reviewed the new features that had been added to the publication in the past year. In addition, she outlined several new activities that would be covered in forthcoming issues. She indicated that with her co-editor, Susanne Kos, the flow of material is now established and is smooth.

12. Ralph Naunton gave a report on the Long Range Planning Committee. Dr. Naunton had requested a mail response to three questions that were sent to the Long Range Planning Committee members. Included in these questions were: 1) are we adequately serving the needs of our fields and our membership; 2) how should we plan to use additional monies; 3) do we need to strengthen our audiological representation and/or representation of other components. The responses to each of these three questions were reviewed and discussed. Two specific recommendations came from these discussions. The first was to establish an ad hoc committee on otolaryngological relations. The second was to poll the membership through *Corti's Organ* to ask questions about how the Society should function. In addition, it was suggested that the membership of each committee be listed in *Corti's Organ*, along with a brief statement on the purpose and scope of each committee.

13. Michael Seidemann reported on the Membership/Promotion Committee. He indicated that two promotional activities had taken place during 1986. First, a letter was sent to each audiology Program Director encouraging student membership. Second, letters were sent to manufacturers to encourage their membership. In an effort to promote otolaryngology membership, a letter campaign was suggested to selected Academy of Otolaryngology groups. The letters would be written and signed by the AAS Otolaryngology Executive Committee members and sent out as directed. Dr. Seidemann indicated that he would follow up on this activity.

A suggestion was made that the American Auditory Society develop a comprehensive membership directory. Ross Roeser indicated that he would prepare sample information and obtain an estimate on costs to be presented to the Executive Committee.

14. Deborah Hayes reported on the Continuing Education Committee. In her report she reviewed the steps that were followed to obtain continuing education from the American Speech-Language & Hearing Association, the National Hearing Aid Society's National Institute for Hearing Instrument Studies, and the American Medical Association. She recommended that AAS review critically membership needs/desires for these credits before committing to a policy of continuing education.

Accreditation will be available from all three organizations at the next two meetings; then a decision will be made as to the importance of each.

15. Susanne Kos presented the names of 396 individuals who had applied for membership since the last Executive Committee meeting. A number of these individuals still required sponsorship, and members of the Executive Committee were asked to sponsor those whom they knew. After reviewing the list, all 396 were approved for membership.
16. Michael Seidemann reviewed the videotaping activities. He indicated that he had between 30 to 35 requests for videotapes from the 1985 meeting. Several procedures

were changed this year to make the videotaping more effective, and he anticipated that there would be additional requests for the tape of the 1986 meeting. He estimated that the videotaping activities would generate a profit for the Society.

17. Seven members of the Executive Committee were up for election during 1987. Bill Stemann was asked to be the new Chairman of the Nominations Committee. Other members on this Committee are Pat Brookhoff, E. Robert Libby, Wayne Staab, and Worthington. They were asked to submit nominations for the Executive Committee within the next 2-3 weeks, prior to January 1, 1987. Two positions will represent audiology, two otolaryngology, two manufacturing, and one hearing science.

18. Wayne Staab was appointed as Vice President/President elect 1987-89.

19. A report was given by President Worthington on the council for Better Hearing Speech Month. In 1985, the American Auditory Society voted to join the Council. Lloyd Bowling was appointed as the American Auditory Society representative. Formal reports were received from him, Dr. Worthington indicated that he would contact Bowling to find out what had occurred up to this point. It was decided that AAS should rejoin the Council for 1988.

20. President Worthington reported on the International Congress of Audiology. In 1985 AAS had received a communication from Moe Bergman requesting that the annual meeting be held with the International Congress in Jerusalem, Israel. Worthington contacted Bergman to indicate that we would not meet with them formally but would help promote their meeting. In addition, Dr. Worthington requested that a special session be held at the International Congress devoted to papers presented by members of the American Auditory Society. No reply from Dr. Bergman has been received to date.

21. President Worthington indicated that the Better Hearing Institute had requested that the American Auditory Society help sponsor an informational pamphlet. For \$3,000 the American Auditory Society could be listed on the back page as a co-sponsor of such BHI brochures. After discussion, a motion was made that the American Auditory Society not fund this activity, and the motion passed.

22. President Worthington requested direct action on having the American Auditory Society contribute to other non-profit organizations. Specifically, a request was received to contribute to the KAM fund. In reviewing by-laws, President Worthington did not see contributions of any type could be given without specific authorization by the Executive Committee. After discussion, it was unanimously decided that the American Auditory Society not contribute to other non-profit organizations unless the contribution is approved by the Executive Committee first.

23. President Worthington suggested that the Society continue to present the Beltone Distinguished Teaching Award in Audiology at its meeting. In the future, Beltone's presentation to the recipient will receive pre-approval by the AAS, and will be presented by AAS President or by his delegate.

24. President Worthington read a letter dated June 30, 1986, which he had received from Dr. Nancy G. Becker, Vice President of Professional and Governmental Affairs of ASHA concerning AAS's request for membership on the Joint Committee on Information Hearing. According to the letter, AAS, along with several other organizations, was given consulting, non-voting membership. To date no notification or invitation has been received by the AAS.

25. Ross Roeser indicated that plans were being made to incorporate the American Auditory Society. This is a high priority at the present time and will occur within the near future.
26. There being no further business, the meeting was adjourned at 6:12 p.m.

Professor Roger N. Kasten Receives Teaching Award

The fifth annual Beltone Distinguished Teaching Award in Audiology was presented to Roger N. Kasten of Wichita State University. This award was established by Beltone Electronics Corporation in 1981 to recognize exceptional teaching in audiology. This is the only teaching award given in our field. It is significant because, by its nature, it recognizes the future of our profession — honoring, as it does, those among us who excel in educating and guiding the next generation of audiologists.

To be eligible for this award, an educator must be nominated by a student and must have at least five years' experience in teaching audiology. Judging is done by a panel of ten professionals from major research and educational institutions and by one student, representing the National Student Speech-Language-Hearing Association. These eleven judges have a difficult task evaluating the nominations and making the final selection.

It was obvious from the list of nominees that the quality of educators nominated this year, as in past years, is outstanding.

Roger Kasten has been affiliated with the Wichita State University since 1971. He is currently organizing and developing the V. Jerry Blue Hearing Aid Research Laboratory at the University. He has also served as visiting Research Fellow at the Western Australian Institute of Technology, as President of the Academy of Rehabilitative Audiology, and as Director of Speech and Hearing Services for the

Institute of Logopedics. Dr. Kasten has taught at Howard and Purdue Universities, and has spent several years with the Veterans Administration's Central Auditory Research Laboratory. He received his bachelor's and master's degrees in speech and hearing therapy from Bowling Green State University, Ohio, and his doctorate in audiology from Northwestern University, Chicago. Since 1982, he has been Chairman of the National Council on Communicative Disorders.

Dr. Kasten is known for the many workshops and seminars he has conducted across the country. His teaching has been described by his students as creative, stimulating, rigorous, and human.

But perhaps the best summation of both the award and the recipient comes from J. Keith Graham, Chairman of the department of Communicative Disorders and Sciences at The Wichita State University. In Dr. Graham's words: "Distinguished teaching encompasses more than what transpires in the classroom: It is the enthusiasm, scholarship, professional leadership, humor, judgment, and sensitivity that pervade all of one's personal and professional life; that become distilled in the classroom, the clinic, the hallways, and the byways; that influence students... often for a lifetime."

The Distinguished Teaching Award in audiology was presented to Dr. Kasten at the AAS annual meeting in Detroit by Society President Don Worthington. Congratulations, Roger, for such a well-deserved honor.

Editorial Board Minutes

of November 30, 1986
Continued from Page 14

Board Transition:

Deborah Hayes recently announced her resignation from the board. Deborah has served as section editor for four years. The board thanks her for her contributions to the development of our journal. As editor I want to especially thank her for her help, and to acknowledge Deborah's high standards of editorial excellence.

Susan Jerger was introduced as the newest member of the editorial board. She will assume the role of section editor of Speech Audiometry beginning with Volume 8. We are fortunate to find a replacement for Deborah who has such outstanding credentials. Beginning with the next issue the section "Speech Audiometry" will be retitled "Behavioral Techniques in Audiology and Otology." In the late 80's the title "Speech Audiometry" does not recognize

the broad possibilities that exist for this section, and we hope that this expanded title acknowledges those possibilities.

Editor's Report

We expect to receive approximately 100 manuscripts this year. Our acceptance/rejection rate is approximately 60/40. We are currently scheduling manuscripts for publication in Number 3 (May/June) of Volume 8, 1987.

For your information I have tallied the average time between receipt of manuscripts and acceptance, and also the average time between receipt and publication of those accepted for the first 7 volumes of the journal. That summary information is shown on the figure, and the breakdown of manuscripts by general subject category is shown on the table.

Figure 1. Average time in months between receipt of manuscripts by the Editor-in-Chief and (a) acceptance and (b) publication.

Lorne Greene takes PSA filming break with AAO's Dr. Jerome Goldstein and BHI's Joe Rizzo.

AAO-HNS and BHI Jointly Produce TV Messages Based on Marketing Studies

Actor Lorne Greene and his wife, Nancy, co-star in a new television public service announcement — jointly produced by the American Academy of Otolaryngology-Head and Neck Surgery and the better Hearing Institute — which will be targeted to spouses of hard-of-hearing persons.

"Our messages are based on the results of recent BHI focus group studies and the Hearing Industries Association marketing survey showing the spouse as the major motivating force behind the hard-of-hearing person," said Richard T. Burger, BHI president. "Surveyed hard-of-hearing persons also ranked Lorne Greene among the highest in sincerity and popularity of the many celebrities in BHI's award-winning program."

Jerome C. Goldstein, M.D., executive vice president of the Academy and a member of BHI's advisory board, noted that this was the second Greene PSA co-sponsored by AAO and BHI, the first having been produced in 1980. "We believe this new PSA is a wonderful way to cooperatively further the hearing field's public information and marketing goals," he said.

Based on the real-life experience of Lorne Greene, who was persuaded by Nancy to do something about his hearing problem, the PSA features a situation that spouses of hard-of-hearing persons can identify with, and one that might encourage them to persuade their spouses to similarly seek hearing help. Videotaped in 60-second and 30-second segments, the PSA is set on the Greene's home tennis court, where Nancy broke her racquet in frustration when Lorne had trouble hearing her. "She urged me to get my hearing checked," said Lorne. "Fortunately, I did. My hearing problem was corrected with hearing aids. Others might be helped medically or surgically. The important thing is that most people with hearing problems can now be helped."

Another new BHI PSA starring Arnold Palmer, made possible by a grant from Knowles Electronics, was the first to benefit from the recent marketing studies. Designed to appeal both to the family doctor and the hearing impaired person, the Palmer PSA is scheduled for November release, followed by the Greene PSA in February.

In Volume 7 No. 6 (December) 1986 issue of *Ear and Hearing* we will acknowledge the approximately 135 individuals who served as reviewers of manuscripts during 1986. We are grateful for their efforts. The peer review process is critical to the success of *Ear and Hearing*. The editorial board is continually seeking other persons who are interested in serving as peer reviewers. In order to qualify as a reviewer, individuals are required to have the highest professional ethics. They serve in a privileged status, in a position of trust. They must be willing to render thoughtful, objective judgements of other professionals' work. Their opinions guide what eventually appears in the refereed literature. In addition they must be willing to return their reviews in three weeks, in order to minimize review time to contributors. If you are interested in contributing to the journal in this important way, please fill in the "Reviewer's Form" found below and return it to the office of the Editor-in-Chief.

Editor's Award for Outstanding Articles

The executive committee of AAS has approved the issue of an Editors' award for outstanding articles that appear in *Ear and Hearing*. The purpose of the Editor's award is to acknowledge manuscripts that exemplify the standard of quality that the *Ear and Hearing* editorial board strives to achieve. The scientific standard to which we subscribe, and the basis on which manuscripts are evaluated include:

- an interesting and well thought out research question
- appropriateness of research design and methodology used in gathering data
- appropriate analysis
- clarity of writing
- timeliness of the subject
- appropriateness to the purpose of the journal

The editorial board recognizes that the decision to award a particular manuscript is a difficult one. In fact, how do you determine THE outstanding article among 60 published in a given volume? Nevertheless we feel that the three articles selected this year represent a high

level of excellence. They represent the quality of article that sets the standard that we are attempting to maintain.

In order of their appearance in the journal, the three articles chosen as outstanding contributions for Volume 6, 1986 are:

The Crib-O-Gram in the NICU: An Evaluation Based on Brain Stem Electric Response Audiometry; Andree Durieux-Smith, Terence Picton, Christopher Edwards, John T. Goodman, and Brock MacMurray; Vol. 6, No. 1.

Cochlear Summating Potential to Broadband Clicks Detected from the Human External Auditory Meatus: A Study of Subjects with Normal Hearing for Age; Gian-Emilio Chatrian, Adelina L. Wirch, Kyoko H. Edwards, Giorgio S. Turella, Mark A. Kaufman, and Jack M. Snyder; Vol. 6, No. 3.

Hearing Loss in the Elderly: An Epidemiologic Study of the Framingham Heart Study Cohort; Eve K. Mosnicki, Earleen F. Elkins, Herbert M. Baum, and Patricia M. McNamara; Vol. 6, No. 4.

Future Plans

Late in '87, *Ear and Hearing* will publish a paid supplement called "Diagnostic Audiology: A Golden Anniversary." This supplement is published in recognition of Jay Sanders' contribution to the audiology profession. It is the proceedings of a symposium held at the Bill Wilkerson Speech and Hearing Center, Vanderbilt University, held during the summer of 1986.

A second supplement in 1987 will be edited by Lu Beck. It will be on the subject of current hearing aid fitting techniques, and will include information on real ear measurements. This timely issue is made possible by a willingness on the part of the publisher to increase our page allowance. This will be the first supplement "on our own" without external funding.

As this year ends I would like to thank the membership for their support of the journal. I also want to thank the editorial board for their help with the editorial process. It is fun to work with the best.

REVIEWER'S FORM

I am interested in serving as a peer reviewer for the journal, *Ear and Hearing*. I understand the need to render thoughtful, objective reviews in a timely fashion.

Probe Microphones

Continued from Page 16

The IGO-1000 is recommended as the system of choice for clinical usage.

Acoustimed HA-2000
\$6350 including Epson printer, one disk drive, color CRT; word proc. software; Impedance probe option \$2500; distributed by And/Or Corp.

This is one of the most flexible of the systems discussed, as it is built around a general purpose computer (BBC Acorn). Unlike the dedicated ROM-based probe microphone systems discussed previously, the Acorn system comes with its own word processor, waveform synthesizer, and speech synthesizer software, and one or two disk drives. The disk drives allow patient data storage and retrieval, and upgrades are made by replacing floppy disks with new software rather than by replacing internal ROMs. Unfortunately, the disk format of the Acorn micro-computer is not compatible with other commonly used personal computers and it appears that the large base of software developed for CP/M and MSDOS type computers will not run on the Acorn. The Acorn computer utilizes a standard alphanumeric type-writer keyboard and special function keys. Commands are initiated with menus and with the special function keys. Applications are limited only by the amount of software provided, and the company is upgrading programs frequently. Speech rehabilitation software has been added, as well as the company's own hearing aid prescription program. Hard copy is produced on a standard dot matrix printer. Liberal comments may be added on the CRT and printed for each set of data in the patient record.

The probe-tube of the HA-2000 is quite soft, so repeated testing of the same patient is possible without much discomfort. Unlike the other systems, the HA-2000 uses only one microphone (with probe-tube) for both reference and measurement purposes. Electroacoustic tests with the HA-2000 are based on a fast Fourier transform (FFT) in which time domain data are displayed and converted to frequency response data. Virtually any input waveform may be synthesized, but the standard stimulus is a click. The spectrum of the click is similar to that of speech-weighted noise but differs in phase. Proponents of this system are quick to point out that, compared to pure tones, clicks are much more like the stimuli hearing aids encounter in real world usage. Only a few repeated clicks are needed to almost totally average out noise in the test environment. With the click stimulus and time domain response, the operator can assess the temporal processing capability of a hearing aid fitting, an area of considerable importance that has previously been almost ignored because of the difficulties of measurement. The operator must be aware that too high a level of click input can easily overdrive the hearing aid circuitry and create nonlinearities. All of the raw time domain data, as well as their associated frequency responses, may be stored for a patient on disk for later analysis, recall, and updating.

In spite of the user-friendly features included, the HA-2000 has been surprisingly lacking in a few basic features. Initially the HA-2000 had no means of hanging the probe tube assembly, so tape was recommended to hold it to the patient's head. The tape method was recently replaced with an ear-hanger wire to hold the probe-tube microphone assembly. Initially, the 250 Hz resolution of frequency responses was inadequate, resulting in jagged curves, especially in the low frequencies. With an FFT-based system, both the lowest measurement frequency and low frequency resolution are inversely proportional to test time. Later software versions have resolved this problem, although longer FFT conversion time still goes hand-in-hand with acceptable frequency resolution. Possibly the greatest drawback of the HA-2000 is that there is no input level autoranging, so the operator has to manually set the preamp gain for the level of unaided or aided signals sensed by the probe-tube microphone. The system then asks the operator to enter this gain setting manually via the key board. This procedure must be repeated each time the signal level changes.

A most powerful feature of the HA-2000 system is the acoustic impedance option. If one knows the acoustic impedance over frequency of a middle ear, given an adequate electroacoustic model of hearing aid circuitry and transducers, the SPL delivered by a hearing aid

in an individual ear canal across the frequency range may be predicted. Thus, when ordering a custom ITE hearing aid, if a dispenser supplies this acoustic impedance data with the normally provided audiogram and patient history data, the hearing aid manufacturer essentially will be better able to predict what frequency response the aid will produce in the patient's ear.

The HA-2000 is recommended as the system of choice for research applications.

Frye 6500

\$8750 complete with ANSI, IEC, multi-curve, plus \$1695 for probe system.

The 6500 is an FFT-based hearing aid analyzer with an optional real ear testing package. The probe-tube microphone system utilized is from Etymotic Research, which incorporates the twin stub tube resonance elimination approach of Elmer Carlson. Actually, the complete 6500 system essentially includes the pure tone testing capability of the popular Frye Fonix 5500Z hearing aid analyzer. Added for testing signal processing hearing aids is a CRT and a pseudo-random noise input signal with either a flat spectrum or a high frequency rolloff like that of speech. For real time observation of the effect of adjusting hearing aid trimmer potentiometers *in situ*, when using the noise input mode, the frequency response is updated every one-half second on the CRT. Hard copy is available on a built-in strip chart recorder. The 6500 uses one microphone for both reference and measurement functions. Required values of speaker drive voltage are stored during the leveling sequence by the computer for later use, resulting in the substitution method of equalization. Although the niceties of data storage on disk, and patient labeling with an alphanumeric typewriter keyboard are absent in the initial 6500 system, this instrument is a pleasure to use.

Bruel and Kjaer 2118/WH 1823

\$9995 complete

This device is basically a modified 2118 hearing aid analyzer, having a Bruel and Kjaer 1/4" microphone with a probe-tube fitting set up on an ear-hanger. It utilizes a warble or pure tone for input stimulus. A built-in X-Y recorder plots in five colors. This is a one microphone system with stored correction curve (substitution equalization method). In fact, the correction curve is stored with battery backup, and thus is retained even after power to the machine is turned off. Computer subtraction of curves allows display of either *in situ* response or insertion gain. Unlike the other systems mentioned in this article, an adaptor (DP 0181) is available to interface the probe microphone to a 4230 sound level calibrator, or to a 4220 pistonphone for calibration. A switch permits the operator to use 1/2" or 1" Bruel and Kjaer microphones for traditional 2cc coupler or ear simulator hearing aid analysis in a test chamber. As with many of the other systems, an output monitor is available for the hearing aid fitter to listen to the sound being delivered in the patient's ear canal. There is no CRT with which to view data as it is developed and no data storage capability.

Horag Earton Invivo

\$5600 Complete with HA-1, HA2 2cc couplers. Dist. by Robert Bosch Corp.

This system uses two microphones and has no computer subtraction of insertion gain. Consequently, a direct measurement of insertion gain is not possible without utilizing the reference microphone in real time to perform a pseudo-subtraction of unaided ear response. To accomplish this, Bosch recommends placing the reference microphone in the unaided ear during the measurement. The validity of this equalization approach is highly dependent on 1) physiological symmetry of the patient's two ear canals and middle ears; 2) symmetry of the loudspeaker radiation pattern at the two ears; 3) equal depth of insertion of the probe-tubes in each ear canal; and, 4) matching of the probe tube microphone frequency responses. It is likely that one or more of these criteria will not be met in everyday use of the device. If the reference microphone is not placed in the opposite ear, the unaided curve will not approximate a flat line. This substantial difference will have to be subtracted from an aided curve manually by the operator. There is no CRT monitor to observe the test data as it is developed. Other than these limitations, the machine contains a

George E. Lynn

In Memory of Dr. George Lynn

Dr. George E. Lynn, a long-time active member of the American Auditory Society, passed away on October 9, 1986, after a prolonged illness of nearly a year. He was a member of the Faculty of the Department of Audiology at Wayne State University School of Medicine for 21 years. Also, for the past 15 years he held an Associate's appointment in the Department of Neurology. Prior to joining the faculty at Wayne State University, he held faculty appointments at the University of Colorado in Boulder, at Colorado State University in Fort Collins, and at Duke University in the division of Otolaryngology. George Lynn received his Ph.D. in 1962 at Northwestern University where Raymond Carhart served as his mentor and major professor.

During George Lynn's academic career, which spanned nearly three decades, he made numerous contributions to the clinical audiology literature, and he published several tutorial chapters in various textbooks. His best known work was focused in the area of neuro-audiology. Along with John Gilroy, M.D., Chairman of the Department of Neurology, George Lynn published numerous articles concerning disorders of the central auditory pathways. His well-documented clinical case studies are regarded as pioneering research concerning central auditory disorders.

His final endeavor, which he initiated about the time of the beginning of his illness, was the establishment of a neonatal testing program

using auditory evoked potentials for newborns who are at high-risk. As a result of his thoughtful planning and dedicated efforts, this needed program was established at one of the hospitals in the Detroit Medical Center, and it has become an important service program for the Detroit Metropolitan community.

George Lynn was enthusiastic about both his work and his leisure activities. He was an active individual who enjoyed several different outdoor sports, especially skiing and horse-back riding. He was also a dedicated family man and is survived by his wife Jan and their four young-adult children — three sons and a daughter.

In recognition of George Lynn's contributions to the field of Audiology, the American Speech-Language-Hearing Foundation has established the George E. Lynn Memorial Research Award in Audiology. This fund will provide small research grants on a competitive basis to young investigators including graduate students. All gifts should be sent to the American Speech-Language-Hearing Foundation specifying the George Lynn Memorial fund. Gifts of \$100 or more qualify the donor to become a Foundation Founder. Mail contributions to: ASHF at 10801 Rockville Pike, Rockville, MD 20852-9979.

George Lynn will be long remembered by many people whose lives he touched, and especially by his friends, his students, and his colleagues.

Reger Conference Produces Text

The proceedings of the Scott N. Reger Memorial Conference have been organized into a text edited by M. J. Collins, T. J. Glatke, and L. A. Harker. This volume contains 22 papers presented at the Reger Conference held in Iowa City, Iowa.

The topics were chosen with a view toward Scott Reger's interest in hearing loss, and they included anatomy, physiology, and psychoacoustic correlates of hearing loss; innovative approaches to the medical and non-medical treatment of hearing loss; and some new looks at old data. It is anticipated that this book will be a valuable resource for advanced students and researchers, providing them with an

update in key areas of inquiry related to sensorineural hearing loss.

The proceeds from the sale of the book will go toward the Scott N. Reger Scholarship Fund for support of research by residents in Otolaryngology and graduate students in Speech Pathology and Audiology at the University of Iowa. Copies of the book are available at a price of \$25.00 (including shipping and handling charges) from:

Campus Stores

FANTASTIC OFFER FOR AAS MEMBERS

Academic Press is pleased to announce a special reduced subscription rate to all members of AAS for the *British Journal of Audiology*. This professional publication consists of four issues a year and is available to Society members at the rate of \$25.00, a significantly lower amount than for traditional subscriptions. This special reduction will apply to individuals who pay out of personal funds and enclose AAS member documentation.

The *British Journal of Audiology* is certainly one of our profession's most outstanding publications. Many landmark articles and research contributions have been included in this journal. This reduced rate provides a unique opportunity which each AAS member should take advantage of.

Payment should be in U.S. dollars by cash, check (payable to Academic Press, Inc. of London), bank draft, or international money order. Credit card payment can be accepted. For further information or to place an order, you may write:

Journals Marketing Department
Academic Press, Inc. of London
24-28 Oval Road
London NW1 7DX
U.K.

Probe Microphones

Continued from Page 17

headband assembly for retaining the microphones, tracking filters for eliminating noise in order to test in an open environment, a built-in strip chart recorder with four-color plots, a warble tone stimulus, and speech-weighted noise for biasing AGC and other signal processing aids during swept-frequency response measurements. Curves may be super-imposed on the strip chart recorder drawing one at a time. A battery simulator provides readings of hearing aid current drain. There is an electrical correction network for drawing a curve of the estimated insertion gain from the 2cc coupler response. It is not known how these correction values were derived or whether they apply to ITE, body, eyeglass, BTE or ITC types of hearing aids.

The following systems are in the process of being introduced during the writing of this article and only limited information is available:

Bio-logic Systems Corp.

Approx. \$2000 for probe mic add-on to evoked potential system.

Both an add-on and a stand-alone system will be available within six months. The add-on system incorporates the two channel traveler LT and Navigator evoked potential systems, which already have FFT capability. The stand-alone system will revolve around a lap-top IBM PC compatible computer with a wireless keyboard. Consequently, with either type of system data may be stored on floppy disk. The FFT algorithm will result in 125 Hz resolution, and there will be "zoom" capability to expand desired sections of the response curves. Two microphones will be used, but the reference microphone may be turned off optionally to permit the substitution method of equalization. Additionally, the reference microphone may be physically separated from the test microphone. Either a pseudo-random noise or a click is used for input stimuli, with external inputs being accepted as well. Hard copy will be available with either a color ink jet printer or with a four color plotter. Like most of the other systems except for the Acoustimed HA-2000, there will be automatic ranging for varying input levels from the probe-tube microphone. Computer subtraction of curves will produce either the in situ response or insertion gain.

Phonic Ear PE1800

\$1000-1200 add-on to the PE2800 hearing aid analyzer.

The PE1800 add-on probe-tube microphone module is now in field test and is expected to be available soon. The PE2800 analyzer utilizes a swept pure tone with 50, 60, 70, and 80 dB SPL input levels. Like the Bruel and Kjaer and Bosch systems, there is no CRT for displaying curves, but there is an X-Y plotter for hard copy. This is a two microphone system which cannot subtract two response curves to determine insertion gain. However, a mylar overlay will be provided for the operator to hand draw the insertion gain after manually subtracting the unaided response from the aided response. The probe microphone will be held in place by means of tape. There is no data storage capabilities.

Registrants check in at conference.

Society hosts 230 attendees at annual meeting.

President Worthington says good-bye.

LaVonne Bergstrom takes over as President.

S.A.S. Goes to Sea

The 1987 Southern Audiological Society Convention will be held aboard the cruise ship, "Mardi Gras," from September 10-13. The convention will offer ten (10) hours of continuing education presentations. Your participation in this convention can be a relevant professional update as well as a real travel bargain for you and your significant others.

The "Mardi Gras" is a 27,250 ton ship that is registered in Panama and has an international crew and service staff. She is air-conditioned throughout with private facilities in each state-room. Inclusions for this meeting will be a Welcome Aboard Party for SAS registrants; full range of entertainment, including nightclub-type show; duty free shopping; all meals and snacks, including sumptuous late nite buffets; gala Captain's Cocktail Party and Dinner; complimentary deck chairs; children's activities; Casino and full run of the ship's pools, spas, and deck sports. The ship will sail from Ft. Lauderdale, Florida, on Thursday, September 10 to Nassau, Bahamas, and return on Sunday, September 13, 1987.

The Southern Audiological Society's ship rate for the cruise will be \$260.00 per person/double occupancy for inside cabins with twin beds or \$295.00 per person/double occupancy for outside cabins. The customary "rack rates"

for this cruise are \$495.00 and \$545.00. A third or fourth person in the cabin will add \$190.00 per person. These rates do not include a \$22.00 port tax.

Special air fares have been negotiated for us with Eastern Airlines. Our official SAS travel agency, ABOUT TRAVEL, Inc., 1A South Semoran Blvd., Orlando, Florida, (305) 275-7494, gets credit for this. SAS attendees will receive a 65% discount off roundtrip "Y" fares or the lowest applicable fare with available seats. To receive the discount you must call Eastern's toll-free Convention Central Hotline and request EZ9P10 rates, and you must be ticketed by ABOUT TRAVEL. The Convention Central phone number is (800) 468-7022 (in Florida, (800) 282-0244).

Ernie Edwards is organizing a top-notch Professional/Technical Program to meet continuing education requirements for licensure and certification. Topics will include electrophysiological techniques for assessment of hearing and hearing aid fitting, and digital hearing aids.

For further cruise information, contact: Bob Harrison, University of Miami, P.O. Box 016960 (R56), Miami, Florida 33101. (305) 549-6451. One must be an SAS member in order to obtain these special rates.

Conference On Current Perspectives in Clinical Audiology - 1987

September 3-5, 1987
Carle Clinic Association
Urbana, IL

Topics: Cochlear Implant Candidacy, Assistive Listening Devices, Diagnosis, Rehabilitation, and Relations with the Medical Community.

Speakers: Robert Fifer, James Jerger, Susan Jerger, H. Gustav Mueller, Frank Musiek, Michael Novak.

1989 AAS Meets and Eats In New Orleans

The 1989 AAS Annual Meeting will be held on Sunday, September 24th, in New Orleans, Louisiana, in conjunction with the American Academy of Otolaryngology Head and Neck Surgery. The meeting site is a spacious and well equipped auditorium at Tulane School of Medicine, located several blocks from the major hotel district and the infamous Bourbon Street.

The scientific program will begin at 8:30 a.m. with a round table discussion entitled "Newborn Auditory Screening: Then What?". Jay Hall, Program Chairman, will moderate a panel discussion by well recognized clinicians and researchers in the area of early identification of infant hearing impairment. Each panelist will present viewpoints on the challenges and problems of implementing hearing screening and audiologic follow-up programs. Special emphasis will be given to the potential impact of federal mandates on early identification and management of hearing impaired children. Questions from the audience will be welcomed.

The remainder of the day will be amply filled with informative and stimulating papers presented by an international collection of hearing clinicians. A highlight of the program will be the Carhart Memorial Lecture delivered by Dr. Ira Hirsh of Central Institute for the Deaf. The Beltone Distinguished Teacher of the Year Award will also be presented.

To top off the meeting day, Chairman of Local Arrangements, Mike Seidemann, has planned an evening of eating, drinking, and dancing that could only take place in New Orleans! Since the site of this debauchery is in the center of the French quarter, there will be no curfew on festivities.

Hotels in the area include the New Orleans Hilton, Marriott, and Sheraton, which are hosting the AAO-HNS convention. You are encouraged to make reservations early to assure a room. And plan to travel to the Crescent City to take part in an exciting meeting and enjoy some real Southern hospitality.

1989 Program Committee members make plans for the New Orleans meeting. Left to right J. W. Hall (chair), Mike Seidemann, and John Rizzi.

Football Great Mike Singletary Stars in New Television PSA

Chicago Bears' football star Mike Singletary, selected to six straight National Football League Pro Bowls, stars in a new Better Hearing Institute television public service announcement made possible by a special grant from Knowles Electronics, Inc., international manufacturer of acoustic transducers.

Singletary, who personally overcame his hearing loss with hearing aids, appears in a scenario with his wife, Kim, who persuaded him to do something about his hearing problem.

"This PSA ties in with results of Institute focus group studies and the Hearing Industries Association marketing survey showing the spouse as the major motivating force behind the hard-of-hearing person," said Richard T. Burger, BHI president. "So our new message features a situation that spouses of hard-of-hearing persons can identify with, and one that may motivate them to encourage their spouses to similar corrective action. We sincerely appreciate Knowles' sponsorship of this important project."

Nancy Knowles, Knowles Electronics board chairman, described the new PSA as "a wonderful way to cooperatively further the hearing field's public information and marketing goals."

Videotaped in 60-second and 30-second segments, the PSA will be issued to the major television networks and 711 stations in all U.S. markets. It is scheduled for fall release, timed with the 1989 NFL football season.

Mike Singletary led the Bears with a career-high 170 tackles in 1988 enroute to his sixth straight Pro Bowl appearance. Singletary was voted AP NFL Defensive Player of the Year, the same honor he received following the 1985 season. Only Walter Payton (nine times) has been to more Pro Bowls in Bear history.

Knowles has funded many other BHI public information projects, including previous television PSAs—one starring Arnold Palmer and another in BHI's special PSA series featuring typical Americans who benefit from available hearing help.

Program Committee members arrange for the main dinner at Arnaud's. All agree that the dining arrangements this year will be spectacular.

Earleen Elkins Honored

Dr. Earleen Elkins was honored by the Association for Research in Otolaryngology at its annual meeting in St. Petersburg Beach in February. The ARO is a scientific organization whose members are scientists and scientist-clinicians dedicated to the study of the ear and the normal hearing process, and of deafness and related communication disorders. The interests of the membership and their scientific papers range widely from those dealing with the normal anatomy, biochemistry, and physiology of the hearing mechanism and the perception of sound, to those dealing with the causes of deafness, disorders of balance, and genetic, drug-induced, and noise-induced hearing loss. In recent years, since its inception, the study and further development of the bionic ear, or cochlear implant, has been an important research topic for discussion at these annual meetings. Much of the research funded at these meetings has been supported by the National Institute of Neurological Communicative Disorders and Stroke. Research funding for hearing science will now be assumed by the new Institute of Deafness and Communication Disorders, just founded by President Reagan in his last months in office, and devoted explicitly to the support of research in normal and impaired hearing.

Dr. Elkins, who has a Ph.D. in speech and hearing science from the University of Maryland,

served as head of the hearing program in the National Institute of Neurological and Communicative Disorders and Stroke. More recently, she was chief of the Neurosciences and Behavioral Research Branch at the National Institute of Alcohol Abuse and Alcoholism. She has now joined the new Institute of Deafness and Communication Disorders, and is expected to play a major role in the development of that Institute's program.

At the most recent meetings of the Association for Research in Otolaryngology, Dr. Elkins was honored with a ceremony and bronze plaque for her outstanding service to the scientific community, particularly in the field of hearing and communication. In the award presentation she was mentioned as someone who has been "especially helpful and supportive, not only to the members of the Association for Research in Otolaryngology, but to the broader scientific community in hearing and communication disorders, and in the process has enormously improved the bureaucratic image." The organization particularly applauded "her kindness, her support, and her advice," and honored her "for those special virtues and for her achievements, of which her new position is just the latest in a long, extended series."

Carhart Lecture To Feature Leader In Our Field

This year's Carhart memorial lecture will be one of the society's most outstanding. Ira Hirsh, Ph.D., has been selected as this year's distinguished speaker. He will address the topic of "The Audiogram and Speech Perception."

Dr. Hirsh is professor Emeritus at Washington University and Central Institute of the Deaf in St.

Louis. He has authored numerous articles and texts in the field of audiology and hearing science. Dr. Hirsh is internationally recognized for his research with the deaf and their acquisition of speech. His lecture will certainly be one of the highlights of this year's meeting.

The President's Corner

CHANGING TIMES

by
Wayne J. Staab

The AAS is in the process of completing its most extensive membership mailing ever. Under the guidance of Jim Curran, Membership Committee member, an impressive mailer has been generated and is being sent to an all-inclusive list of potential members from a variety of disciplines having an interest in the area of hearing. The enthusiasm within the Organization is very high, and membership rolls are expected to be the highest in the history of AAS.

Increased membership is also reflected in a wider diversity of interests. Consequently this must be reflected in the annual meeting scientific program content. Historically, AAS has held an independent one day meeting just prior to or concurrent with either the American Academy of Otolaryngology or with the American Speech-Language-Hearing Association. The program has been of the highest caliber, but has also, by necessity, been intensive and of short duration for each presenter. The papers selected for inclusion in the program are the best of those submitted. However, what happens when we have more good papers to list than the program time frame allows for? This is not necessarily the situation as it exists

now, but could become a reality with membership increasing and reflecting a wider range of interests. Additionally, will the papers offered be of the content areas to continue to attract the broad interests of this anticipated membership increase? The question therefore that must be addressed is: should a change in the format be considered?

AAS membership occupations tend to fall into two distinct areas; technical and clinical. Our Organization should provide presentations applicable to both - and this has been the history of AAS. However, with membership increases (and corresponding increases in attendance at the annual meeting), the demands on the Program Committee become greater. Will the accepted papers match the interest areas of the membership, or do the accepted papers dictate the type of members belonging to AAS? How can we meet the demands of the attendees? How do we resolve the issue of having to sit through two or three

papers to get to the one we have a real interest in? How do we find a facility large enough and equipped properly to seat the 300 plus attendees? How can we provide more extensive papers in certain areas of interest?

Perhaps AAS needs to provide concurrent presentations. Perhaps AAS should consider invited papers on selected topics to reflect the interest areas of its membership. A stand-alone meeting is a topic of conversation to suggest.

My purpose is not to yield a particular format, or even to insist that a change be made. However, with the AAS Long Range Plan about to be formulated, and with the strong possibility of AAS having its largest membership enrollment, this issue could have a significant impact on the future direction of AAS. As in my request in the last issue of *Corti's Organ*, let your Executive Board members know your thoughts. Remember, it's your Organization - you make AAS what it is and what it will be!

From The Editor

As can be seen from this issue, it's time once again to elect members to AAS' Executive Committee. Like our Annual Meeting, this election is a particularly important event for our membership.

As in previous years, some of our most outstanding members are nominees this year for Executive Committee positions. It was so exciting to me to read each nominee's statement regarding their affiliation with AAS and their impressions concerning the Society's accomplishments and role.

A consistent theme was evident throughout the nominees' statements. AAS is one of the most viable and respected professional organizations representing our field. The cross discipline make-up of our membership brings a complexion to the

Society that few other groups can offer. Our diversity allows for varying perspectives on the challenges and issues facing AAS.

If you've forgotten or begun to doubt the significance of your AAS membership, you will certainly want to read all nominees' statements. Our brief history can boast of many accomplishments, not the least of which is the development of one of the most respected journals in our field. What the Executive Committee candidates have written is a great reminder of our strength as an organization. Do what you can to insure that our strength continues: support the Society and the Executive Committee. Vote for the candidates of your choice and help make AAS the dynamic group of choice in the 1990's.

Letter to the Editor

I would like to bring to your attention a letter I recently received from John Oyiborhoro. John is a native Nigerian. He received his audiology training in the United States and returned to Nigeria in approximately 1983 to establish a training program at the University of Port Harcourt. He has problems that would seem overwhelming to those of us practicing in the United States. They have over 100 million people with few professionals to provide care for the hearing impaired. Perhaps one of your readers has equipment or books to assist John in establishing his training and service programs. If so, I would encourage them to write to him directly.

Robert W. Keith, Ph.D.
Professor
University of Cincinnati

Faculty of Education
Univ. of Port Harcourt
Port Harcourt
Nigeria

Dear Dr. Keith,

I delayed writing because I thought that I would be able to acknowledge (at the time of writing) the receipt of the donated books. It appears they may take a little longer before arriving this way. Thank you very much for your invaluable assistance

through SHARE. Please, help express our profound gratitude to all those who make SHARE work.

A major problem that is facing us currently is that of lack of instruments to conduct research. It may sound incredible but it is true that we lack a basic impedance bridge and a dependable clinical audiometer. There are, as you will expect, a lot of research areas to be explored. We are over one hundred million in my country. Much of the data often taken for granted in the U.S. are not available here. We do not have any hearing instrument manufacturers or distributors in Nigeria from whom we can readily request donations of hearing evaluation equipment. The field is relatively new. I have been unable to assist those who have come to receive my service here or conduct any meaningful research that can be shared with other professionals, principally due to lack of instrumentation. Even though you may not be in a position to do any more than the much valued and appreciated assistance that you have offered to us already, I am reporting all this to indicate the direction of our greatest need.

Once again, thank you very much for your time and efforts.

Sincerely,

John M. A. Oyiborhoro, Ed.D., CCC

Ake Flock Presented Award of Merit

Dr. Ake Flock, Professor and Chairman of the Department of Physiology, Karolinska Institute, Stockholm, Sweden, has been named the 1989 recipient of the Award of Merit, the highest award offered by the Association for Research in Otolaryngology for research and scholarly leadership in otolaryngology and the communication disorders. Honored for his contributions to knowledge about the way inner ear cells translate sound energy into encoded neural impulses in the brain, Professor Flock's past work has explored the mechanisms by which acoustic signals can be encoded by the nervous system's inner ear receptor. He has been largely responsible for describing the muscle-like proteins in the inner ear that give

the ear its remarkable sensitivity, dynamic range, and tuning characteristics. His work has advanced our theoretical understanding of the active processes of the inner ear which are capable of tuning and focusing energy in selected bands to permit us to understand complex signals like speech in noisy environments. These advances are the first steps leading to improved methods for helping the hearing handicapped.

Born in Gotenburg, Sweden, Professor Flock attended medical school and received his Ph.D. at the Karolinska Institute, Stockholm in 1965. He then studied at the Bell Laboratories in New Jersey in 1965-1967 before returning to Sweden to continue his research.

CLINICAL EXCHANGE

Editor's Note:

The following article is reprinted by permission of Gerson H. Aronovitz, M.D. of Atlanta and the *Southern Medical Journal*. This manuscript originally appeared in the *Southern Medical Journal*, Vol. 81, August, 1988, pages 978-980. It is the hope of *Corti's Editorial Board* that this article provides information of benefit to our readers in the management of their clients with otitis media.

Treatment of Otitis Media With Cefuroxime Axetil

GERSON H. ARONOVITZ, MD, Atlanta, Ga.

ABSTRACT: Cefuroxime axetil and cefaclor were compared for efficacy in the treatment of acute otitis media with effusion. Sixty-four pediatric outpatients had tympanocentesis for culture, and then were randomized to a ten-day course of treatment with cefuroxime axetil or cefaclor. *Streptococcus pneumoniae* and *Haemophilus influenzae* were isolated from 25 (39%) patients, respectively. Treatment was beneficial in 26 (90%) of the patients. Treatment failed in five (24%) of the cefaclor-treated patients, and in only three (10%) patients who received Cefuroxime axetil. *Haemophilus influenzae* was the initial causative pathogen in a disproportionate number of treatment failures. This study demonstrates the efficacy of cefuroxime axetil in the treatment of otitis media.

ACUTE OTITIS MEDIA with effusion (acute OME) is a very common illness among children. In a prospective study of 2,565 children followed up from birth until 3 years of age, 47% and 71% of children had their first episode of acute OME by 1 and 3 years of age, respectively.¹ Many children have multiple episodes of acute OME during the preschool years, a fact that warrants particular concern in view of the insidious complications of acute OME, ie, impaired development of language, learning disabilities, and speech impairment.^{2,4}

A variety of antibiotics are used in the treatment of acute OME,⁵ all directed toward coverage of the major pathogens *Streptococcus pneumoniae*, *Haemophilus influenzae*, and *Branhamella catarrhalis*. Since approximately 75% of *B. catarrhalis* isolates⁶ and 14% to 20% of *H. influenzae* isolates^{7,9} produce beta-lactamase, it is important that the antibiotic have relative stability toward betalactamases, as cefuroxime does. Cefuroxime axetil, an ester prodrug of cefuroxime used for oral administration,^{10,11} is rapidly de-esterified to release its parent antibacterial agent.

This study was designed to compare the safety and efficacy of cefuroxime axetil and cefaclor in the treatment of acute OME. Cefaclor was chosen because of its widely reported efficacy in patients with acute OME¹²⁻¹⁸ and its known safety profile.¹⁹

METHODS

Candidates for enrollment in the study were pediatric outpatients with acute OME, diagnosis of which was based on erythema or opacification of the tympanic membrane by pneumatic otoscopy, and the usual signs and symptoms, ie, fever, otalgia, and irritability. The presence of effusion was assessed by diminished mobility of the tympanic membrane on pneumatic otoscopy and indicative findings on tympanometry.

Patients were excluded from the study if they had a history of hypersensitivity to any cephalosporin, anaphylactic reaction to a penicillin, use of an antibacterial drug within the past 48 hours, or any gastrointestinal illness that could interfere with absorption of orally administered antibiotics.

Informed consent was obtained from the parents after discussing the purpose of the study and the potential benefits and risks of participation.

Procedures

After the auditory canal was debrided of cerumen and cleansed with aqueous benzalkonium chloride, tympanocentesis was done with an 18 gauge spinal needle connected to a DeLee suction catheter with a mucus trap. Aliquots of the effusion were removed from the trap with a sterile loop, streaked on 5% sheep blood agar and chocolate agar, and incubated in 5% CO₂ for a maximum of 48 hours. Susceptibilities of isolates to cefuroxime, cephalothin, and ampicillin were determined by the Kirby-Bauer method using NCCLS susceptibility criteria.²⁰

Patients were reevaluated between the third and fifth days of treatment, two to four days after treatment, and two weeks after treatment. Clinical laboratory tests before and after treatment consisted of a complete blood count with differential, determination of BUN and SGOT values, and urinalysis with microscopic examination.

Treatments

Patients were randomly allocated to treatment for ten days with cefuroxime axetil or cefaclor. Cefuroxime axetil (Ceftin) was administered as 125

Clinical Exchange (Continued from Page 2)

mg bid for patients less than 2 years old and as 250 mg bid for patients 2 or more years of age. These dosages were selected to achieve an average daily dose of 30 mg/kg. Parents were instructed to crush the tablets and mix the powder with a small amount of food for administration.

Cefaclor (Ceclor) was administered as 40 mg/kg/day (to a maximum of 1 gm per day) divided into three equal doses. This drug was dispensed as a suspension with a pediatric dosing spoon.

Assessment of Outcome

Response to treatment for each patient was assessed as cure, improvement, or failure. Cure was defined as resolution of symptoms during treatment, with absence of middle ear effusion two weeks after treatment. Improvement was defined as resolution of symptoms during treatment, but with persistence of middle ear effusion for two weeks after treatment. Failure was defined as inadequate response to a minimum of three days of treatment. Repeat tympanocentesis was considered only for patients in whom treatment failed.

Results

Sixty-four patients were enrolled in the study. The distribution of patients by treatment group according to age, sex, and location of infection is shown in Table 1. Composition of the two treatment groups was comparable, except that the cefaclor group had a greater proportion of infants between 6 and 11 months of age.

The profile of bacterial isolates from these patients was consistent with that of previous reports (Table 2). One or two types of bacteria were isolated from specimens of effusion from 52 patients (81%), while samples from the remaining 12 patients (19%) yielded no growth by aerobic culture procedures. The predominant isolates were *S pneumoniae* (25 patients; 39%) and *H influenzae* (23 patients; 36%). *Branhamella catarrhalis* and *Streptococcus pyogenes* were each isolated from three (approximately 5%) patients. Nine of the 23 isolates (39%) of *H influenzae* were resistant to ampicillin in vitro. Since the results from my practice in 1980 showed *S pneumoniae* in 43% of patients, *H influenzae* in 27% of patients, and

no growth in 20% of patients,¹⁴ there has been little change in the profile of pathogens of acute OME.

Of the 29 patients with bilateral acute OME, 19 patients had bilateral tympanocentesis before treatment. The same bacteria were isolated from both ears in 15 patients (79%); in the other four patients (21%), one organism was isolated from one ear and effusion from the opposite ear was sterile.

Beneficial response was achieved in 26 of 29 evaluable patients treated with cefuroxime axetil (90%) and in 16 of 21 evaluable cefaclor-treated patients (76%). Treatment failed in five (24%) of the cefaclor-treated patients, compared with three (10%) of those treated with cefuroxime axetil (Table 3). Each patient who had treatment failure was young, ie, 7 to 16 months old in the cefuroxime axetil group and 7 to 24 months old in the cefaclor group. In addition, *H influenzae* was the initial isolate from four of the five patients who had treatment failure with cefaclor. One of the three patients who had treatment failure with cefuroxime axetil had *H influenzae* infection, while the other two had both *H influenzae* and *S pneumoniae* isolated before treatment. Repeat tympanocentesis was done for three of the five patients with cefaclor treatment failure and two of the three patients with cefuroxime axetil treatment failure, and specimens from each confirmed persistent bacterial infection; therefore, although *H influenzae* was responsible for the infection in 23 patients (36%) at presentation, it contributed to seven of the eight failures (88%).

DISCUSSION

Cefuroxime axetil was at least as effective as cefaclor in treating acute OME. No adverse effects were noted with either drug.

The incidence of ampicillin-resistant *H influenzae* in acute OME continues to increase nationwide, as well as in my own area. In this study, nine (39%) isolates of *H influenzae* were resistant to ampicillin. Resistant *H influenzae* along with *B catarrhalis* accounted for 11 (11%) of the 64 cases of acute OME evaluated.

Given these observations, the availability of beta-lactamase-resistant antibiotics becomes increasingly important. This study has demonstrated the efficacy and safety of cefuroxime axetil in acute OME. The bid dosage schedule is advantageous in that it eliminates the need for a dose during day care or school attendance, thus enhancing the ease of use and compliance. Future studies are needed to explore the utility of cefuroxime axetil as an additional option for prophylaxis of recurrent otitis media with effusion.

ARO Meets in St. Petersburg Beach

The 12th Annual Midwinter Meeting of the Association for Research in Otolaryngology (ARO) was held February 5-9, 1989, in St. Petersburg Beach, Florida. The meeting was attended by more than 725 people who heard over 430 papers and viewed posters on a wide range of research topics. The meeting was highlighted by Symposia on the Cochlear Nucleus, Nasal Response to Illness and Animal Psychophysics. Invited papers were presented on a number of topics: Sound Localization, Auditory Processing of Complex Sounds, The Efferent Systems and Vestibular Function. Beautiful weather, exciting new research developments, and the excellent presentations made this one of the best ARO Midwinter Meetings ever.

A full report on the status of the new Institute on Deafness and Other Communication Disorders (NIDCD) at the National Institutes of Health (NIH) was presented by Dr. Jay Moskowitz, the interim director of NIDCD. The ARO continues to work with the NIH in establishing the NIDCD.

The ARO's Award of Merit went to Dr. Ake Flock of the Karolinska Institute of Stockholm, Sweden. Dr. Flock was honored for his pioneering research in several fields. In recent years Dr. Flock's research has revealed a number of fundamental facts concerning the function of many structures within the inner ear, especially structures of the hair cell. This work has paved the way for a new understanding of how the inner ear transduces the vibrations of sound. A certificate and the traditional gold tie clasp symbolizing the inner ear were presented to Dr. Flock on behalf of the ARO and its members.

In addition to honoring Dr. Flock, the ARO presented special awards to Mrs. Geraldine Dietz-Fox and Dr. Earlene Elkins. Mrs. Fox was honored for her efforts in initiating and sustaining the movement to establish a new NIH institute for deafness and other communication disorders. Dr. Elkins was recognized for her many years of

work at the NIH as the chief program officer for researchers in hearing. Mrs. Fox and Dr. Elkins were presented plaques from the ARO Council and Members.

Dr. William A. Yost of the Parmlly Hearing Institute of Loyola University of Chicago presided over the meeting as the fifteenth President of the ARO. Dr. Nadol of the Boston Ear and Eye Infirmary assumed the presidency of the ARO at the Business Meeting at which Dr. Ilsa Schwartz of Yale University was elected President-Elect and Dr. Robert Dobie of the University of Washington was voted in as the new ARO Council Member. The other members of the ARO Council for 1989-90 are: Dr. David Lim of Ohio State University, Dr. Charles Parkins of Louisiana State University, Dr. Allen Ryan of the University of California at San Diego, and Dr. James Saunders of the University of Pennsylvania.

Seventy-two new members were approved as Active, Associate, or Corresponding Members at the Business Meeting. The membership of the ARO is now approximately 1000 members. The members represent all areas of research in Otolaryngology from all over the world, including members from over twenty foreign countries. In addition to the Midwinter Meeting the ARO co-sponsors the Research Forum which will take place September 25th and 26th, 1989, in New Orleans as part of the Annual Meeting of the American Academy of Otolaryngology-Head and Neck Surgery. A newsletter and other informational publications are also provided to the members each year.

The 1990 Midwinter Meeting will take place February 4-8, 1990, in St. Petersburg Beach at the Tradewinds Hotel. For additional information about the ARO, please contact the ARO Office, 6525 N. Sheridan, Chicago, IL 60626, (312) 508-2706 [FAX - (312) 508-2719].

Nominees For Audiology

James W. Hall, III
Ph.D.

Dr. Hall holds his Ph.D. in Audiology from Baylor College of Medicine. He is currently Associate Professor and Director of Audiology, Division of Hearing and Speech Sciences and Department of Otolaryngology at the School of Medicine of Vanderbilt University.

According to Dr. Hall: "The American Auditory Society and *Ear and Hearing* provide valuable services to hearing health care professionals in general, and to audiologists in particular. *Ear and Hearing* is the primary scientific journal for clinical audiologists. The annual meeting of the Society regularly provides a forum for exchange of current clinical information on hearing, hearing impairment, and management of the hearing impaired. Finally, and uniquely, membership of the American Auditory Society and its executive committee consists of persons from varied hearing health care professions, including audiology, hearing science, industry, and otolaryngology. There are other organizations representing professional and political interests for each of these sectors, but the American Auditory Society alone attempts to unite them 'to increase knowledge of human hearing, to promote conservation of hearing, and to foster habilitation and rehabilitation of the hearing impaired.' While each of the three services just noted is important to American Auditory Society members, the final characteristic—ecumenical membership—sets it apart from other organizations and provides the foundation for an exciting future."

William F. Rintelmann,
Ph.D.

Dr. Rintelmann holds his Ph.D. from Indiana University. He completed a post-doctoral fellowship at Northwestern University. Dr. Rintelmann is currently Professor and Chairman of the Department of Audiology at Wayne State University School of Medicine in Detroit.

According to Dr. Rintelmann: "A unique feature and major strength of the American Auditory Society is that the membership is composed of a broad spectrum of individuals with varying backgrounds, interests, and activities related to hearing impairment, hearing conservation, and aural rehabilitation. The range of activities of the membership encompasses: (1) teaching; (2) research; (3) clinical evaluation/patient management; (4) aural rehabilitation including hearing aid selection, fitting, sales, and counseling; and (5) product (i.e., hearing aids, audiometers, etc.) development, engineering, manufacturing, and sales. No other organization has such a broad scope of activities related to serving the hearing impaired. Because the membership of the American Auditory Society deals with nearly every aspect of serving the needs of hearing handi-

capped persons, the Society has a unique opportunity to serve as a catalyst for technological development of amplification devices and also for advancement in patient evaluation/management skills. The leadership of the American Auditory Society should strive to find the best possible ways to maximize open communication among all of its members in order to foster "state-of-the-art" advances in education, research, patient care, and product development."

Jean H. Lovrinic,
Ph.D.

Dr. Lovrinic is currently a Professor in the Department of Speech, Language and Hearing at Temple University of Philadelphia. She holds her Ph.D. from the University of Pittsburgh in Audiology.

According to Dr. Lovrinic: "The interdisciplinary structure of the American Auditory Society and its focus on both normal and disordered hearing mark it as unique. In this era of a proliferating number of professional special interest groups, the lack of political focus or intent in the function of the Society constitutes still another of its novel features. Our journal, *Ear and Hearing*, has earned a reputation for excellence and serves a vital role. It is my opinion that if it isn't broken, you don't fix it. If you have something which works like a charm, you treat it with care and respect. Thus, the nature of the Society and its goals must not change. Our journal must be maintained and strengthened in any reasonable manner. In short, our Society merits our contributions to its continued viability."

Laszlo K. Stein,
Ph.D.

Dr. Stein holds his Ph.D. from Northwestern University. He is currently Director of the David T. Siegel Institute for Communicative Disorders, Michael Reese Hospital and Medical Center in Chicago and Associate Professor for the Department of Surgery (Otolaryngology) at the University of Chicago.

Dr. Stein states: "The American Auditory Society was founded to increase the knowledge and understanding of the auditory process, to

promote conservation of hearing, and to further habilitation and rehabilitation of persons with hearing impairments. For many years, the Society has been in the enviable position of advancing these aims principally through its publication, the journal *Ear and Hearing*, and the annual meeting. By design, the Society has concentrated its limited resources in these areas. That this strategy has been successful is evidenced by the fact that *Ear and Hearing* is now generally acknowledged as the leading journal in clinical audiology and that our annual meetings have assumed a life of their own. Whether the Society will choose to meet its stated aims solely through its journal and annual one-day meeting or use its steadily increasing resources to expand into other areas will be the principal question facing the membership and its elected Executive Committee to address such matters as relationships with other organizations, representation of special interest groups within the Society, a more visible stance on governmental policies affecting hearing disorders and hearing research and quite possibly, the very nature of the multi-disciplinary makeup of the Membership and Executive Committees. Paramount during all this will be the need to protect the integrity of the journal and, indeed, to do everything to enhance the stature and excellence it now enjoys. The next several years may well mark the transition from youthful growth to an era of maturation for the Society."

Don W. Worthington
Ph.D.

Don W. Worthington, Ph.D., received his B.S. and M.S. degrees from Utah State University, and his Ph.D. from Northwestern University. He is currently Director of Audiology and Vestibular Services and of Clinical Services at Boys Town National Institute for Communication Disorders in Children.

Dr. Worthington states: "The American Auditory Society was initially conceived and organized by a group of highly respected professionals representing audiology, otolaryngology, the hearing aid industry, education of the hearing impaired, and auditory neurophysiology. These professionals felt that there was a need for an organization which would provide a platform for the interchange of information among disciplines. Sixteen years have not passed, during which time the AAS has worked toward achieving this interaction of varied professions and professionals."

The AAS serves as a unique model for interdisciplinary or multidisciplinary interaction. While major conflicts have existed between organizations representing the interests of only one profession, the AAS has been able to set those differences aside and work for common goals and objectives. Members of the AAS can be proud of what they have accomplished. Through the outstanding journal, *Ear and Hearing*, and the annual meetings, AAS provides an exceptional forum to foster interaction among all disciplines interested in hearing and hearing disorders.

The future, like the past, rests on the ability of the AAS to continue to expand its membership and provide the forum for collegial interaction among all disciplines interested in hearing.

Territorialism or support of a single profession's interests would defeat the purpose of the AAS, and result in its eventual downfall. If selected to serve on the Executive Committee, I would work for the continued growth and development of this unique organization."

Allison M. Grimes,
M.A.

Ms. Grimes is Director of Audiology for the Hearing Society for the Bay Area in San Francisco, California. She holds her M.A. in Audiology from the University of Denver and her M.A. in Speech Pathology from Humboldt State University.

Ms. Grimes states: "The American Auditory Society is facing a crucial test in the next few years, one which will require strong and carefully directed leadership from its Executive Committee. With the advent of the American Academy of Audiology, there are those who question the need for two organizations. Such persons, I believe, fail to understand the fundamental differences between the American Auditory Society and the American Academy of Audiology. The American Auditory Society has a vital role to play in the professional lives of audiologists; it is the only non-partisan professional group where audiologists interact with their colleagues in industry and medicine for ONE purpose: to serve, through research, rehabilitation, and product development the needs of the hearing impaired population. We cannot allow ourselves to believe that the American Academy of Audiology will ever supplant the role and need for the American Auditory Society, and it is my hope to be able to continue the work which I have done over the past few years as an Executive Committee member and as a member of the Long-Range Planning and Membership Committees to strengthen and preserve the American Auditory Society as a vital, viable organization for the audiologic community and the larger professional community serving the hearing impaired."

Nominees For Otolaryngology

**Patrick E. Brookhouser,
M.D.**

Dr. Brookhouser completed his M.D. at Johns Hopkins University School of Medicine in Baltimore, Maryland. He served as Chief Resident of Otolaryngology at Johns Hopkins Hospital. He was named as Fellow in Surgery and Fellow in Otolaryngology at the University. Dr. Brookhouser is currently Director of The Boys Town National Institute for Communication Disorders in Children in Omaha, Nebraska. In addition, he is Father Flanagan Professor and Chairman of the Department of Otolaryngology and Human Communication, Creighton University School of Medicine.

He states: "During my service on the Executive Committee of the American Auditory Society, I have been impressed by the Society's record of achievement, as well as by its potential to make future contributions to our field. As intended from its inception, the Society's annual meeting serves as a major forum for exchange of ideas among otolaryngologists, audiologists, auditory scientists, and industry representatives interested in hearing disorders. Founding of the new National Institute for Deafness and Other Communication Disorders at NIH attaches even greater importance to such creative interdisciplinary interaction. Our journal, *Ear and Hearing*, has achieved acceptance as a respected and widely-read publication, but it must be provided with continuing support by our membership to maintain its present high level of quality. Particular emphasis must be given to encouraging participation by younger members of the Society as Executive Committee Members, as presenters at the annual meeting, and as authors of articles in *Ear and Hearing*. In short, I believe that the American Auditory Society should continue to serve its essential role as a *non-political* meeting ground for all of us interested in hearing and hearing disorders."

**Richard T. Miyamoto,
M.D.**

Dr. Miyamoto received his M.D. degree from the University of Michigan and an M.S. in Otolaryngology from the University of Southern California. He completed his residency in Otolaryngology-Head and Neck Surgery at Indiana University, and a fellowship in Otolaryngology and Neurotology at the Otologic Medical Group and House Ear Institute in Los Angeles, California. Currently, he is Professor and Chairman of the Department of Otolaryngology-Head and Neck Surgery at the Indiana University School of Medicine. Dr. Miyamoto was one of the original seven co-investigators in the national clinical trial of cochlear implants in children. He serves on the National Institutes of Health Communicative Disorders Review Committee and is the principal investigator on an NIH grant evaluating sensory aids in deaf children. He is the author and co-author of over 80 publications and abstracts.

Dr. Miyamoto states: "I am honored to share this candidacy for re-election to the Executive Committee of the American Auditory Society. The Society has taken a leading role in serving as a sounding board for a complex multidisciplinary approach focused on the hearing impaired population. The goal of bringing together professionals working in this complex, dynamic arena is one of ever-increasing importance, and I fully endorse the efforts of the Society to this end. I continue to support the concept of bringing together the inputs of academia, industry, and the broad clinical domain of our membership into a unified whole."

**Paul R. Lambert,
M.D.**

Dr. Lambert is currently Associate Professor of Otolaryngology-Head and Neck Surgery and Director of Otolaryngology at the University of Virginia Health Sciences Center in Charlottesville, Virginia. He completed his M.D. degree at Duke University and his Otolaryngology residency at UCLA. Dr. Lambert was a Fellow in Otolaryngology at the House Ear Institute and the Otologic Medical Group.

According to Dr. Lambert: "The establishment of the National Institute of Deafness and Other Communication Disorders represents one of the major achievements of our time for the areas of hearing science and management of the hearing impaired. It will now be important for the American Auditory Society to be a leader among the coalition of organizations that will bring together people and resources during these early critical years of the Institute. As a member of the Executive Committee, I would work toward that goal. The Society's expertise in diagnostic testing and rehabilitation should enable it to be an integral part of an effective lobby to increase Congressional appropriations for the Institute. I welcome the responsibility of helping the American Auditory Society have an important and continuing presence in the development and function of the Institute."

**Sean R. Althaus,
M.D.**

Dr. Althaus completed his M.D. at the University of Buffalo and his Otolaryngology residency at the Veterans Administration Hospital of San Francisco. He completed a clinical fellowship at the House Ear Institute in Los Angeles. Dr. Althaus is a member of the American Otological Society; the American Laryngological, Otological, and Rhinological Society; the American Neurotology Society, and the American Academy of Otolaryngology-Head & Neck Surgery, Inc. Dr. Althaus is currently a Clinical Associate in the Department of Otolaryngology-Head & Neck Surgery, University of California San Francisco Medical Center.

He states: "The American Auditory Society fills a vital role in linking the various disciplines involved in the acquisition and application of knowledge regarding the human auditory process. This should remain the Society's primary goal, as we strive to bring the latest developments in our knowledge of auditory physiology and applied technology and education to the attention of the hearing-impaired public and of the professionals who serve them."

Nominees For Hearing Science

**David J. Lilly,
Ph.D.**

Dr. Lilly completed his Ph.D. at the University of Pittsburgh. He is currently Director of Audiology at Good Samaritan Hospital and Medical Center in Portland, Oregon.

According to Dr. Lilly: "In fewer than 20 years, the American Auditory Society has emerged as a major association for many workers in audition. The success of our Society stems, in part, from the diverse backgrounds of our members. Indeed, the American Auditory Society has been unique in its ability to provide a common forum for audiologists, engineers, hearing aid specialists, otolaryngologists, neurophysiologists, physicists, and psychoacousticians. During

(Continued on Page 8)

**Margaret W. Skinner,
Ph.D.**

Dr. Skinner holds her Ph.D. from Washington University. She is currently Director of Audiology and Assistant Professor of Audiology in the Department of Otolaryngology-Head and Neck Surgery at Washington University School of Medicine.

Dr. Skinner states: "Since its inception 15 years ago, the American Auditory Society has become an extremely important, unique forum for those of us from different professional fields to exchange information and work together toward our common goals 'to increase knowledge of human hearing, to promote conservation of hearing, and to foster habilitation and rehabilita-

(Continued on Page 8)

Nominees For Industry

Harry Teder

Mr. Teder holds his degree from Dartmouth College. He is currently Chief Engineer of hearing instruments at Telex Communications, Inc.

According to Mr. Teder: "The growth of the American Auditory Society to its current prominent position in the hearing sciences field is convincing proof of the need for such an interdisciplinary, information-oriented organization. Our journal, *Ear and Hearing*, is, of course, our primary means for disseminating information in our fields, and it has done a superb job. It has occurred to me that if I were forced to reduce my professional reading list to two publications, *Ear and Hearing* would be one of the two (the other published Down Under). One concern I have is the danger of "burnout" among the busy professionals that help produce the magazine; comparing the names on the Editorial Board in Volume 1, Number 1 in 1980, to those in December, 1988, shows two of the original ten veterans still in harness. This, hopefully, indicates that we have both a healthy turnover of participants and continuity from the past. Let us hope this desirable balance continues."

**David A. Preves,
Ph.D.**

Dr. Preves is Vice President of Research and Development of Argosy Electronics in Eden Prairie, Minnesota. He has B.S. and M.S. degrees in Electrical Engineering from the University of Illinois and a doctorate in Biomedical Engineering from the University of Minnesota.

Dr. Preves states: "In the field of hearing health care, the challenges for developing a better understanding of the auditory system and for providing better aural rehabilitation are so great that a concerted effort is needed with all parties working together toward common goals from within their individual disciplines. Once we have obtained a better understanding of how both normal and pathological auditory systems function, it may be possible to design and fit more effective hearing prosthetics. Toward these goals, the American Auditory Society is a unique organization, bringing together members of such diverse disciplines as otolaryngology, psychoacoustics, audiology, and hearing aid design. The organization facilitates the germination of new ideas, identifies research needs, and examines possible new clinical practices. The frontiers of the hearing health care field are further advanced from interactions at annual meetings of the Society, as well as via papers published in its excellent journal, *Ear and Hearing*."

Health Care Providers Will Run 26 Miles For Hearing Help Awareness

A 1989 "Run for Better Hearing" team of hearing help providers and hearing field dignitaries will again run 26 miles on June 17th to focus public attention on available hearing help. The team will participate in the eleventh annual Grandma's Marathon Run in Duluth, MN, and personify the interdisciplinary support for cost-effective public information projects of the Better Hearing Institute, according to Richard T. Burger, BHI president.

The run is a fund-raising effort to strengthen BHI hearing awareness projects, which have generated the equivalent of more than \$178,000,000 in broadcast time and print media space since 1973. BHI's program has been spearheaded by famous Americans who overcame hearing loss. They include Art Carney, Norm Crosby, Phyllis Diller, Richard Dysart, Nanette Fabray, Lou Ferrigno, Florence Henderson, Bob Hope, Surgeon General C. Everett Koop, M.D., Arnold Palmer, Richard Thomas, Charlene Tilton, and many others.

Joining BHI executive director Joe Rizzo will be hearing help providers from across the U.S. and from around the world, including Michael Brocco, Starkey, Miami Lakes, FL; Duncan Clifton, Gennum, Burlington, ONT; Reg Garratt, Knowles Electronics, and BHI board member, Franklin Park, IL; Bruce Gliken, dispenser, Houston, TX; Bob Hanrahan, dispenser, Wilmington, DE; Dr. Gil Herer, American Speech-Language-Hearing Association president, Washington, DC; David Hilton, Rexton, Plymouth, MN; Dr. I. King Jordan, Gallaudet University president, Washington, DC; Dr. Mead Killion, Etymotic Research, Elk Grove, IL; Richard Marschinke, Dahlberg, St. Louis Park, MN; Marco Parodi, Gfeller AG president, Bernafon, Switzerland; Rae Reynolds, Cochlear Corp., Englewood, CO; Nita Rizzo, Joe's "better half," Springfield, VA; Dr. Ross Roeser, Callier Center director, audiologist, and BHI board member,

Dallas, TX; Sharon Roeser, Dr. Roeser's wife, Dallas, TX; Chuck Walton, Activair/Duracell, Bethel, CT; Ron West, Cochlear Corp. president, Englewood, CO; Wayne Whitney, dispenser, Strum, WI; and Michael Winship, Hearing Services president, Eden Prairie, MN.

Organizing and coordinating this year's campaign is a steering committee that includes Al Bruce, chairman, Starkey; Jim Anderson, Qualitone; Pat Koepke, Dahlberg Electronics; Bud Raas, Earmold Design Inc.; Bob Tischbein, Starkey; Mike Winship, Hearing Services; and Tom Yates, Rexton.

Key Run supporters to date include: Activair/Duracell, American Academy of Otolaryngology-Head and Neck Surgery, American Auditory Society, Argosy, Audiotone, Beltone Electronics, Bernafon, Best Labs/Fidelity of Florida, Cochlear Corp., Dahlberg Electronics, Eveready, Fine-tone, Frye Electronics, General Hearing Instruments, Gennum Corp., Goldentone, GN Danavox, Hal-Hen/Widex, *Hearing Instruments* magazine, *Hearing Journal*, Hearing Services Inc., Hearing Technology Inc., Knowles Electronics, Lang Hearing Instruments, 3M/Hearing Components and Disposables, 3M/Hearing Health, Magnatone, Maico, Marcon, National Hearing Aid Distributors, National Hearing Aid Society, Nicolet Audiodiagnosics, Omni Hearing Systems, Oticon, Phonic Ear, Qualitone, RAY-OVAC, Resistance Technology, Rexton, Siemens Hearing Instruments, Starkey, Telex, United Hearing Systems, Unitron, and Voroba Technology.

Supporting earmold laboratories include: All American Mold Labs, Anthony Earmold Labs, Earmold Design Inc., Emsee Labs, Emtech Labs, Microsonic, Mid States Labs, Pacific Coast Labs, Precision Mold Labs, and Westone. *Hearing Instruments* magazine will again host Run festivities in Duluth.

1989 Society Meeting

The 1989 Annual Convention of the American Auditory Society is scheduled for New Orleans on September 24.

The charge of the Local Arrangements Committee is always to surpass the arrangements of the previous year. This year there will be no exception to that rule.

Our convention this year will be in conjunction with AAO-HNS.

The meetings will be held at Tulane Medical Center, which is a very short cab ride from the convention hotels and French Quarter.

Following the meeting we will have a memorable evening of dining and entertainment. The Society banquet will be at the famous Arnaud's

Restaurant in the French Quarter. The newly renovated banquet facilities at Arnaud's include a unique Mardi Gras museum. Following the banquet, we will have '50's-'60's music and dancing by one of the outstanding bands of New Orleans.

For those AAS members who will not be registering for hotel rooms through AAO-HNS, we have made arrangements for rooms at the new Riverside Hilton. Reservation information will be forthcoming in the near future, along with other convention announcements.

The New Orleans weather is quite favorable in late September. There are many activities throughout the city for the entire family, so plan to bring the family along.

First Annual American Academy Of Audiology Meeting Is Overwhelming Success

by: Eric Reynolds

"AUDIOLOGY - A NEW BEGINNING," was the theme of the first annual meeting of the American Academy of Audiology (AAA) held April 21-24, at the beautiful Kiawah Island Resort near Charleston, South Carolina. The meeting, which was kicked off by an exceptional opening night party sponsored by Starkey Laboratories, Inc., offered attendees up to 18 hours of continuing education in a broad range of topics covered in a series of tutorial sessions, poster sessions, workshops, a "CROSS FIRE" luncheon, and a panel discussion. In addition, the meeting featured 45 commercial exhibitors displaying products such as hearing aids, instrumentation, and publications reflecting the state of the art and science of Audiology.

When planning the meeting, the executive committee and advisory board of the academy attempted to develop the kind of activity that would be of help to Audiologists in their professional lives. To achieve this goal, tutorial sessions lasting one to one and one-half hours each were conducted by a panel of invited participants having expertise in specific areas. These expert panels addressed major topics and issues that impact current as well as future aspects of the field of Audiology. Tutorial session topics, which were presented over a two day period, included: Issues in Private Practice; Decision Making in Rehabilitative Audiology; Current Issues in Pediatric Audiology; Adaptive Business Strategies for Future Profit; Update on Selection and Evaluation of Hearing Aids; Digital and Hybrid Hearing Aids; Audiologic Evaluation: Yesterday, Today, and Tomorrow; Current Trends in Educational Audiology; Recent Concepts in Auditory Evoked Responses; New Issues in Aging; Cochlear Implants in Children; and Central Auditory Processing Disorders. The format of these sessions reflected a departure from that of the "traditional" convention format in which specific research findings are reported in a series of lectures lasting a relatively limited amount of time. All sessions were conducive to active participation in discussion, and many attendees took advantage of the opportunity.

Thirty poster sessions were displayed for the purpose of presenting new research findings to the entire profession in areas such as auditory evoked responses from ECochG to the P300 response, hearing aids, vestibular evaluation, hearing impairment in the elderly, and the application of neural networks and computers to Audiology to name a few. The poster sessions were on display throughout the majority of the meeting, providing ample opportunity for all attendees to analyze them thoroughly.

Five intensive workshops designed to provide in-depth exposure to various topics and new techniques to a small number of people concluded Saturday's meeting agenda. The five workshop topics, which were presented simultaneously, included: Evoked Potential Monitoring in the Operating Room; Vestibular Evaluation; Brain Mapping; Calibration: Complying with the Standards; and Practical Aspects of Otoacoustic Emissions. Interestingly, three of the five workshops included topics that some feel do not belong in the realm of Audiology.

Perhaps the most thought provoking activities of the meeting were the six one and one-half hour informal "CROSS FIRE" luncheons occurring simultaneously on Saturday. The executive committee and advisory board intended for these luncheons "to foster small group discussion" and to "provide an opportunity for members to interact over professional areas of mutual interest". Controversial issues were discussed and, as it turned out, debated. Topics of discussion included: Audiology Needs a Professional Doctorate; Non-profit Corporations Should Not Dispense Hearing Aids; Central Auditory Dysfunction: Fact or fiction; Controversies Surrounding Implants in Children; The Role of the Audiologist in the General Practice of Neurophysiological Measurements; and Why You Should Work With but not for an Otolaryngologist in

Private Practice. Those attending the luncheon were free to select the topic of most interest to them. What a great concept!

Dr. James Jerger, distinguished co-founder and honorable president of the AAA, was unfortunately unable to attend the meeting. However, following a meal accompanied by musical entertainment courtesy of Drs. Chuck Berlin and Roy Sullivan, his presidential address, presented via videotape, was featured as the highlight of a banquet Sunday evening. In his presidential address, Dr. Jerger reviewed the history of Audiology in the United States and attributed the very existence of the profession to the "unrelenting efforts" of a relatively small number of individuals. These individuals, whom he referred to as "giants of the past," were C.C. Bunch; Raymond Carhart; Leo Doerfler; William O. Hardy; Grant Fairbanks; Hallowell Davis; Richard Silverman; Ira Hirsh; Wendell Johnson; Mack Steer; Hayes Newby; and Kenneth O. Johnson who, in Dr. Jerger's view, was "the single individual who has had the most influence on the profession as we know it." Undoubtedly, Dr. Jerger too stands among this group of eminent individuals.

Dr. Jerger went on to discuss the current trends in, and their effects on, Audiology as an independent profession. As the field has grown, audiologic activities, some of which are unconventional, have become much more diversified. And while this diversity is good in that it "strengthens our financial base" and "heightens the importance of our position in the health care system," it is bad in that it has spawned "a tendency for those who follow a particular path to want to redefine the entire profession in their own image". Thus, with all the great strides that the profession has made, Dr. Jerger said of the many battles still to be won, "the biggest battle is with ourselves". In concluding this discussion, Dr. Jerger stated, "We can, and should, argue these matters among ourselves, but there is an urgent need to close ranks, suspend our differences, and present a united front when we deal, as we must, with related professions, related professionals, government agencies, third party insurers, etc. We cannot afford the luxury of intra-professional warfare when the future of the entire profession is at stake." Dr. Jerger's professional address was characterized by his usual eloquence, and to have to quote from and paraphrase it truly serves as an iniquity.

A panel discussion focusing on the future of Audiology concluded the meeting on Monday morning. The panelists presented a number of issues deemed to be in need of resolution if Audiology is to prosper as an independent profession in years to come. Included among those issues discussed were: the need for a professional doctorate in Audiology (Au.D.); the expansion of the scope of Audiology to include the provision, performance, and interpretation of clinical procedures such as facial nerve ENOG, ENG, posturography, visual and somatosensory evoked responses, etc.; the need for federal recognition of and funding for research in Audiology; the need to apprise the consumer and the referring professions of the field of Audiology; the need to upgrade the clinical, as well as academic, education of Audiologists; and the need for board certification in areas of Audiology such as aural rehabilitation, evoked potentials, etc.

Of utmost importance, kudos to the program committee, chaired by president-elect Dr. Fred H. Bess, for a meeting which 570 attendees can attest was superbly formatted and conducted. Reportedly, the number of attendees more than doubled that initially expected. Thus, remarkably, while still less than one year old, it is apparent that the AAA is well on its way to becoming a force in the field of Audiology. Indeed a professional organization, "of, by, and for Audiologists" has arrived.

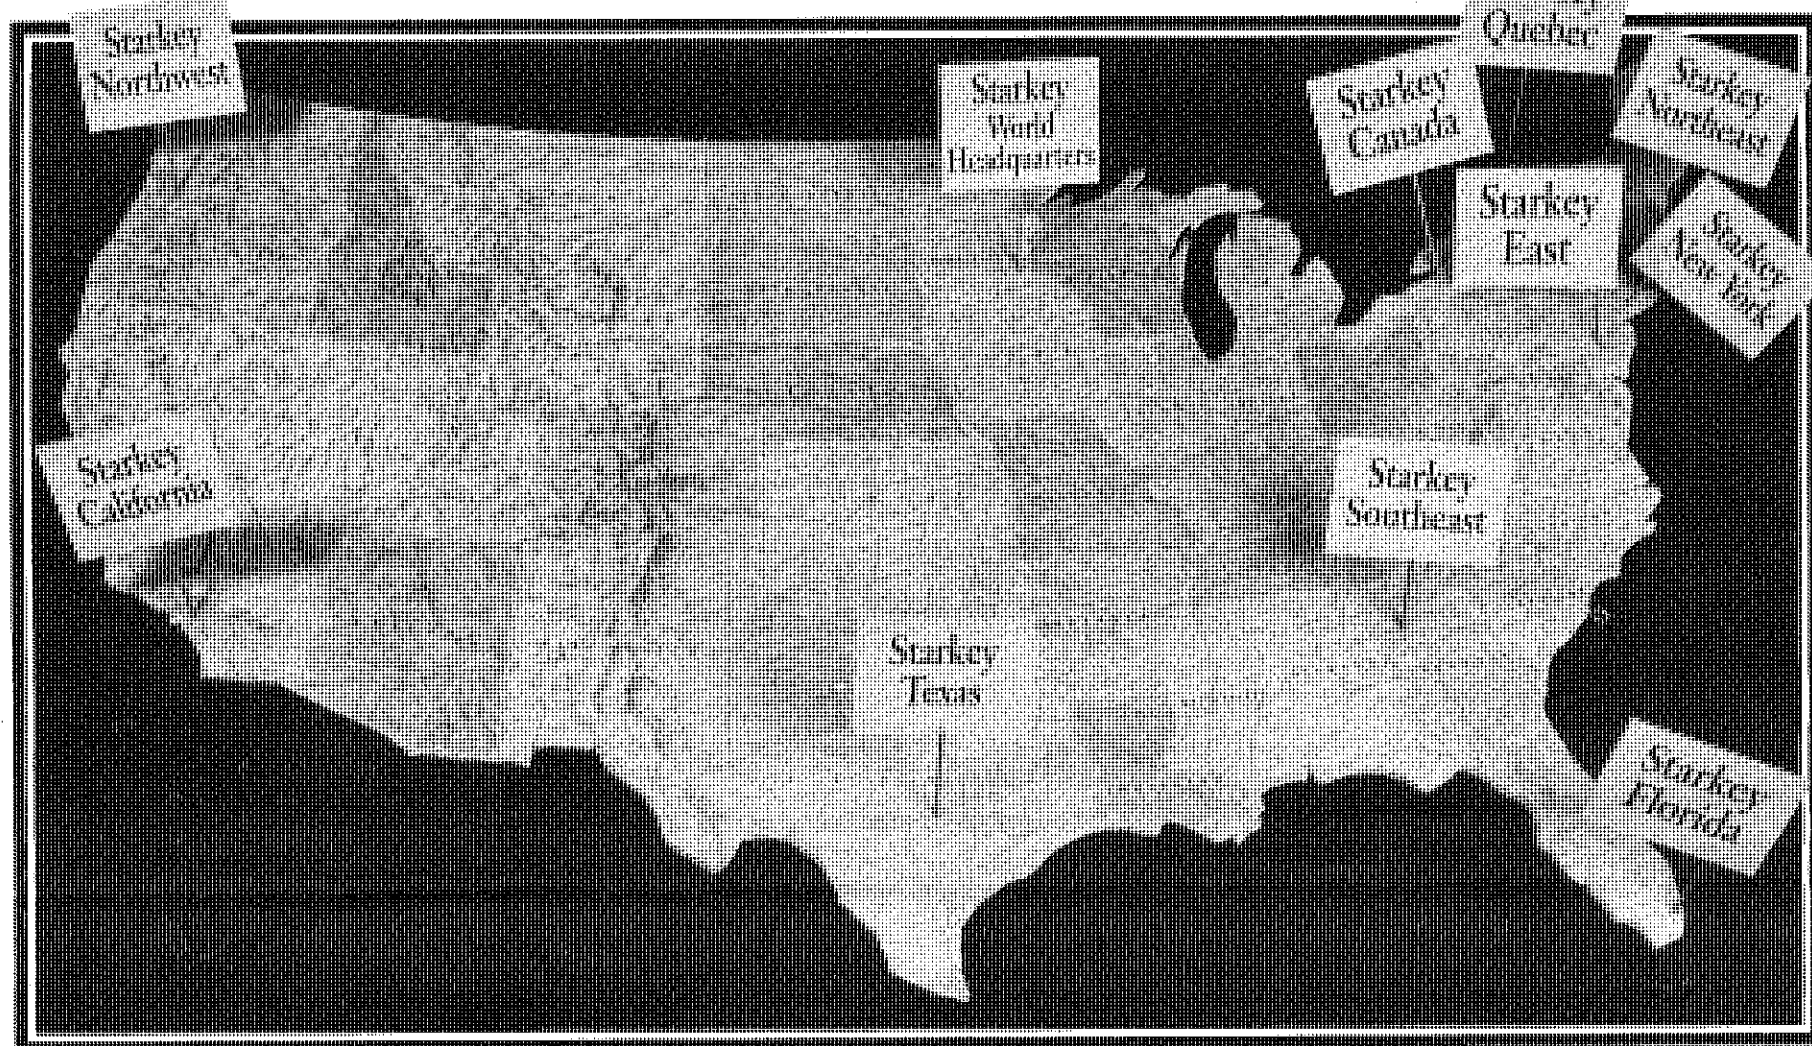

The second annual convention of the AAA, chaired by Dr. Linda J. Hood, will be held April 26-29, 1990 at the Fairmont Hotel in New Orleans, Louisiana. Drs. Chuck Berlin and Roy Sullivan, keep your musical instruments tuned!

Position Available

Auditory Physiologist: The department of Otolaryngology, University of Miami School of Medicine, has an opening for a full-time Research Scientist. This position is on the University's tenure track. The preferred areas of research interest and background include artificial hearing [43.63Mb, 43.66Ts], hearing physiology [43.63Hx, Kz, La, Nc, Pd, Qe, Sg, and Th], and assessment of hearing [43.63Rf, 43.66Ts, 43.66Yw]. Beyond developing an active research program of his/her own, the candidate will guide research activities of residents and clinical faculty. Some teaching is also required. The ideal candidate must have earned a terminal degree (Ph.D., Sc.D., etc.) and have demonstrated productivity through significant publications and grants. Academic rank and salary are commensurate with experience. Please send CV to: W. Jarrod Goodwin, Jr., M.D., Dept. Otolaryngology (D-48), University of Miami School of Medicine, PO Box 016960, Miami, FL 33101, or call (203) 785-2594.

The University of Miami is an
Equal Opportunity/Affirmative Action Employer

We've Got You Covered!

Starkey Offers The Best Repair Value In The Industry.

Sure, there're plenty of hearing aid repair services. But when it comes to giving you the best value for your repair dollar, nobody has you covered like **Starkey All Make Repair Service.**

Being the world's largest independent repair facility does have its advantages. With eleven locations throughout the US and Canada, we provide the unequalled convenience and turnaround others only wish they could offer. Plus, our size carries clout with original components manufacturers. If we replace a volume control, count on it being a new one from the original manufacturer.

Then again, what's better than big? Even though our 100 plus technicians have an average 15 years' repair experience, what really matters is that each specializes in a specific make and model to ensure optimal repair efficiency and performance.

And speaking of covered, Starkey's unconditional Full Service Warranty goes beyond just the work performed in repair, covering the complete instrument for the full warranty and grace period.

All this plus an image-enhancing delivery package that displays your true professionalism, and shows your client that they've made the best choice in coming to you for their service needs.

While a lot of people might repair hearing aids, **NOBODY** has you covered like Starkey All Make Repair Service. And if you've been letting someone else repair your aids, why pay more just to get less?

David J. Lilly, Ph.D.

this same period, our journal has become an important archival repository for manuscripts concerned with nearly every aspect of audition. The rapid and equitable review process instituted by *Ear and Hearing* and its minimal publication lag are attracting first-rate manuscripts. Moreover, the 'special issues' on selected topics have become required reading in many training programs. The growth and success of the American Auditory Society and *Ear and Hearing* could not have occurred without the dedication and efforts of its officers, editors, and Executive Committee. In consequence, I consider it an honor and a challenge to have been chosen by the Nominating Committee to serve as a candidate for election to the Executive Committee. If elected, I shall do my utmost to foster the continued growth of our Society in an environment that emphasizes scientific achievement and clinical excellence, while

avoiding the 'professional' and political issues that have attenuated the growth of so many other organizations.

(Continued from Page 5)

Margaret W. Skinner, Ph.D.

tion of aurally impaired individuals.' Through the well-planned scientific sessions of the Annual Meetings and the rigorous editorial policy of *Ear and Hearing*, the Society has promoted excellent clinical research, much of which has stimulated state-of-the-art delivery of clinical services in the United States, as well as in other countries. In this era of rapid technological development and an aging population, the Society has an opportunity to foster an even greater understanding of hearing impairment and of ways in which its impact on communication can be minimized. The continued growth and commitment of the Society's membership are essential for realizing these goals."

Fall 1985-Winter 1986

Carhart Memorial Lecturer

Samuel F. Lybarger

Introductory Remarks by President

Don W. Worthington

Samuel F. Lybarger is a native of Wilkensburg, Pennsylvania, a suburb of Pittsburgh. He is a graduate of Carnegie-Mellon University, with a B.S. degree in Physics. Entering the hearing aid field in February 1929 on a part time basis while still in school, he has continued in this area ever since. Most of his work has been in hearing aid engineering through the vacuum tube and transistor eras. He is the inventor or co-inventor in 22 U.S. patents relating to hearing aids and audiometers. A few of these patents include; the first master hearing aid fitting device, bone vibrators including the ones in extensive current use, wearable hearing aids with inductive telephone pickup, magnetic microphones, and one of the first directional hearing aid designs.

Since about 1935, Sam Lybarger has been active in standards work related to hearing aid measurements and audiometry. He has served as either a member or chairman of national and international working groups responsible for approximately 10 standards dealing with hearing aids, and 6-8 standards dealing with audiometer specifications and calibration. He has served capacities in organizations related to the hearing aid industry. He has been a contributor to various acoustical and audiological publications (22 published papers), numerous presentations, and has written chapters in nine books. In his long career at Radio Ear he worked as a Laboratory Assistant, Hearing Aid Engineer, Chief Engineer, Executive Vice-President and subsequently President. After retiring in 1973, he has continued his activities in the hearing aid field as an acoustical consultant.

He was one of the original members of our organization, served on the Executive Committee and was President in 1979. It is indeed a pleasure to introduce Samuel F. Lybarger, this year's Carhart Memorial Lecturer.

Samuel F. Lybarger

It is indeed an honor and a privilege to have been asked to give the Carhart Memorial Lecture this year. The fields of hearing measurement and prosthetics are greatly indebted to the pioneering work of Raymond Carhart.

I feel very fortunate to have been able to make the acquaintance of Dr. Carhart when he was working with hearing impaired U.S. Army personnel at the Deshon Army Hospital in Butler, Pennsylvania, near Pittsburgh, and to have been in touch with him on other occasions over the years when he was at Northwestern University. It was at Deshon, I believe, that Ray developed his well-known battery of tests for evaluating hearing aid fittings that is still widely used. At Deshon, each hearing aid candidate went through a prescribed series of listening experiences with three different makes of hearing aids, selected from a hearing aid "library" on the basis of the Carhart test battery. The candidate wore each aid for two weeks, partly at post and partly at home, before a final decision was arrived at jointly by the audiologist and the candidate. Aids were purchased by the Army from participating Pittsburgh hearing aid dealers. Patients then spent about eight weeks in an aural rehabilitation program at Deshon. At that time, (mid 1940's) all aids were of the vacuum-tube type and most of them had rather large "A" and "B" batteries separate from the microphone-amplifier unit.

In Dr. Liden's lecture last year, many of the important scientific contributions made by Raymond Carhart during his very active career were ably described. What has strongly impressed me is the great number of Dr. Carhart's students and associates who have also made outstanding contributions in the fields of audiology and hearing science. The training and inspiration passed along to a large group of

1985 Annual AAS Meeting Voted The Best

In 1985, reasserting our autonomy, the society convened at the Hyatt Regency Hotel in Atlanta, GA., concurrently with the American Academy of Otolaryngology. More than 140 audiologists, otolaryngologists, otologists, research scientists, students, and other affiliated professionals attended the diversely program of educational and technical sessions.

The day began with a Run for Better Hearing by the hale and hearty just after dawn led by our illustrious leader, Ross Roeser, and his wife, Sharon. The weather was made to order, and the runners arrived all fit for the president's opening remarks.

The highlight of every reunion of the society is the Carhart Memorial Lecture. This oration is presented each year by an outstanding member whose career has been distinguished by contributions to the field of human hearing. The executive committee invited Samuel Lybarger to make the 1985 address. Sam graciously accepted and enlightened us in his tempered engineering parlance, on the subject of "Coupler to Insertion Response Factors".

Special events included the awarding of plaques to departing executive committee members, to the Carhart lecturer, to the Beltone Distinguished Audiology Teacher of the Year, and to the secretary-treasurer of (AAS) for his enthusiastic and all-persasive activities within and on behalf of this multi-disciplinary organization. The recognition of Ross Roeser consisted of a mini-roast, partly in the form of a slide show of Ross as only an intimate could have told it. Fellow audiologist former classmate, Mike Seidemann, missed nary a fault nor an attribute in his commentary.

The day's meeting concluded with a professional and social call by Derald Brackman to open dialogue between AAS and AAO regarding dwindling numbers of physicians in the ranks of the academy. He made it clear that the academy would like to see an increase in the number of other workers in the hearing health field. Some of our society audiologists were concerned that they had paid their dues, only to be relegated to "second class citizens" lacking voting rights. Dr. Brackman expressed some surprise that such concerns exist. In the end it was decided that an AAO committee would study the issue of academy membership and draw up a resolution encouraging participation in that organization's annual congresses.

The evening's entertainment planned by Atlanta resident, Tad Zelski, perpetuated the society's reputation for light-heartedness. The historical Fox Theater provided an old world atmosphere for a cocktail buffet of tantalizing food and drink accompanied by the lively and danceable music of a three piece orchestra. Many of our friends really kicked up their heels. A fitting grand finale to a long but stimulating day.

With each passing year our attendance grows. The 1986 meeting will be held in Detroit in conjunction with ASHA. Bill Rintelmann is the chairman and everything is in readiness for a return engagement to this northern city. Moreover, the appointment of Lazlo Stein as 1987 coordinator guarantees that the tradition of exciting meetings will continue. In the year of his tenure we will convene in Chicago, continuing our policy of meeting on alternate years with the AAO. Larger attendance is anticipated each year as membership increases.

(See Pages 6 & 7 for Convention Pictures)

Student/Resident Membership Category Approved By Executive Committee

At the 1985 meeting of the American Auditory Society Executive Committee a student/resident membership category was approved beginning January 1986. This category of membership will allow students/residents in training to join the American Auditory Society at a significant reduction over the \$35.00 membership rate. The approval of this category will

allow students and residents to have full membership privileges, including subscriptions to *Ear and Hearing* and *Corti's Organ*. The dues for the student-resident membership were set at \$20.00 per year. Page 8 of this issue of *Corti's Organ* contains a membership application that can be submitted by students-residents for 1986 membership.

Virginia Berry & Susanne Kos

New Editors Take Reign Of Corti's

After 3 years as Editor-in-Chief, Suzanne Greening Brown is turning over Corti's to fellow AAS members Virginia Berry and Suzanne Kos. The AAS Executive Board approved this appointment at its meeting in October.

Virginia Berry has been an active member and supporter of AAS since 1978. She assisted with the planning and operation of the 2 Society Conventions held in New Orleans, her home town. Now living in Little Rock, Arkansas, Virginia is the State Consultant for Educational Audiology with the Arkansas Department of Education.

A graduate of Vanderbilt University, Virginia has held positions in medical audiology, supervision, university training, administration and much more. She has served on ASHA Committees and is currently the President of the Arkansas Speech, Language and Hearing Association. Virginia brings varied experience and interests with her to this new position as Editor.

Susanne Kos, assistant editor of *Corti's Organ*, has been an integral part of the AAS since its beginning in 1974. At that time she was working at the Callier Hearing & Speech Center in Dallas while completing her MA training at North Texas State University. She participated in

the founding of the AAS and has served as an executive committee member and as assistant secretary from the Society's inception to the present. At the November, 1985 meeting she took on another responsibility with the AAS of Assistant Editor of the *Organ*, primarily handling advertising.

Ms. Kos worked at Callier Center until 1980, at which time she left to enter private practice as a dispensing audiologist. For four years she managed a branch office of a metropolitan retail organization. In October, 1984, she became self-employed, opening her own office in Arlington, TX.

Thanks Suzanne Brown for a job well done. Welcome Virginia Berry and Suzanne Kos!!

Second International Otology Workshop Scheduled

On April 1-5, 1986, the Second International Otology Workshop will be held in Riva del Garda, Italy. Distinguished faculty from around the world will discuss current research and trends in hearing aid technology, cochlear implants, neurology of hearing, diseases of the ear, and much more. For full program details, contact:

CRS Amplifon
Via Ripamonti 129
20141 Milano, Italy

This sounds like one program not to miss!!

From The Editor...

When I was asked by the Executive Committee to become the Editor of *Corti's Organ*, I was both complimented and overwhelmed. My professional ego was thrilled that the officers of our Association would have this amount of confidence and faith in my abilities. But--my personal ego was scared! The thought of "following in the footsteps" of the series of experienced Editors who came before me was frightening.

Rather than letting the fear consume me, I looked on this position as my ultimate challenge. My goal is to have this publication become more than that "newspaper" that is delivered a few times a year. The American Auditory Society is an Association with two publications. Granted, *Ear and Hearing* is the professional journal of AAS. That does not mean that *Corti's Organ* can not also be a viable means of communication.

Corti's Organ can and should be our vehicle for a more relaxed exchange of clinical and scientific information. This publication is our opportunity to share research, express concerns, discuss issues and report findings without the usual intimidation of journal style. *Corti's Organ* is the voice of the Association and, typically, only a very few take advantage of it.

Corti's Organ can be **anything** we want it to be, and everything we want it to be. But, the "we" in that statement is not the royal we. For this publication to be the voice of the Association, every member must take responsibility. As Editor, I see my role as Team Captain. No Editor should have the right to dictate the total direction of a publication nor should the Editor have the responsibility of generating every issue. It's always easy to be critical of things we had no part in. Criticism usually takes less energy than creativity. But--we are an energetic group.. Channel that energy and your abilities in a positive direction.

I promise to commit myself to producing a quality publication AAS will be proud of. You, as members, need to commit yourselves to being a necessary part of the entire process. Do you want *Corti's Organ* to be used only to publish directory information, meeting abstracts and agendas, election results, etc? I don't! Share your experiences with the membership in whatever form you want. Any clinical or case management information you are excited about, the membership will be excited about.

As a national organization, our publication should reflect national input. As a member, I don't want to read issue after issue covering the concerns of a "select" few. I want to read about innovative procedures, changing trends, new technology, the better mouse trap, whatever. In addition, keep us posted on honors, awards, travels, and all news. Expose yourself!!!

An "official" publication doesn't have to mean inflexible, rigid data reporting. A wealth of information can be conveyed in an enjoyable manner. Let's all work together to make *Corti's Organ* a unique publication that makes the American Auditory Society a landmark in professional associations.

Speech for the Deaf

London, England
July 9 - August 15, 1986

East Texas State University is offering a six semester hour course in speech for the deaf at the University of London. The course is being offered through the Institute of Anglo-American Studies, an academic collegium co-sponsored by the University of Southern Mississippi, East Texas State University, the University of South Alabama and Phi Theta Kappa.

The course will be taught by British professors in the very heart of oralism and visits will be made to British oral schools for the deaf. The course can be taken for graduate or undergraduate credit and, if approved by your school district, will count toward career ladder requirements.

Although final plans are not yet complete if you are interested contact:

Frank L. Brister, Ph.D.
Director, Communication
Disorders Center
East Texas State University
Commerce, Texas 75428
Phone: 214-886-5910

The approximate cost is expected to be \$2000 which includes airfare, tuition and lodging.

This is the eighth year of the British Studies Program and many other courses are also offered as well as short term courses. If you have questions in general about this program contact:

Glenn P. Fournet, Ph.D.
Associate Director,
Institute of Anglo-American
Studies

Minutes of the Corti's Organ Editorial Board Meeting

Members present: Virginia (Anderson) Berry, Susanne Kos, Ross Roeser

Place:
Hot Springs, Arkansas

Date:
September 11, 1985

The meeting began by discussing the winter/Spring 1985-86 issue. The primary material for this issue will include Sam Lybarger's Carhart address, minutes from the 1985 Executive Committee and Editorial Board meetings, announcements of the Editorial Board changes, and highlights and photos of the 1985 meeting. It was agreed that the issue should be in the mail at least by the first few weeks in January. It was also agreed that the issue would be printed in Little Rock and shipped to Dallas for mailing.

Future issues will include advertisements. Susanne Kos agreed to have this as her primary responsibility as the Assistant Editor for *Corti's Organ*. She agreed to write a letter that would be sent to all potential advertisers before the end of the year. Ross Roeser indicated that he would generate a mailing list that would be used for sending the material. It was agreed that the rates would be \$250.00 for a full page, \$150.00 for a half page, and \$100.00 for a quarter page. All matters dealing with advertisement would be sent through Susanne Kos.

Of the revenues generated by advertisement, 25% would be split equally between the Editor and the Assistant Editor of *Corti's Organ*. Virginia Berry raised a question about the format of *Corti's Organ*. She indicated that she would like to explore changing the newspaper format to something more permanent. There was no objection, although the newspaper format was felt to be less expensive than any other format. She indicated that she would explore costs for changing the format.

It was stated that an active editorial board would benefit *Corti's Organ*. Each editor would be responsible for generating material that would be submitted to the editor. The Editorial Board in the past was based on regional representation and did not generate much information, since the board members were not contacted routinely to solicit information. It was suggested that the Editorial Board members be selected to generate material for feature columns in *Corti's*. The columns could be based on ideas that were featured in past issues, such as the interrogatory, "name that lesion", "AAS Trivial Pursuit", etc. Or, new features could be generated. Virginia Berry indicated that she would consider different individuals for each feature column and contact them.

The final issue discussed was the budget. There has been no specified annual budget for *Corti's*, primarily because the costs have been so reasonable. Virginia Berry indicated that she would look into costs of printing *Corti's* in Little Rock and then,

Roeser Roasted & Toasted by Exec

Editor's note: The following is an excerpt from a speech given by Don Worthington at the 1985 AAS Convention.

On September 22, 1972, a group of 20 highly respected professionals, representing the disciplines of audiology, otolaryngology, the hearing aid industry, education of the hearing impaired, and auditory neurophysiology, met to discuss the formation of an organization that would fill an existing need in the area of human hearing. While not all persons attending that inaugural meeting felt another organization was needed, the large majority did. They felt a need for an organization that would provide a platform for the interchange of information between disciplines. The group founded the American Auditory Society.

One year later, in 1973, the first formal meeting of the Society was held in Dallas, Texas, with 50 interested persons in attendance. At that meeting, the Executive Committee was elected. Aram Glorig was appointed President, Dix Ward was appointed Vice-President, President-Elect and Ross Roeser was appointed Secretary-Treasurer. During the years since 1973, there have been eight different Presidents of this Society, but only one Secretary-Treasurer.

Every President, myself included, are deeply indebted to Ross for his diligent, meticulous dedication to details, his unsurpassed ability to work with people, his total support of the President and most important, his vision of what the American Auditory Society could become.

In effect, he serves as an Executive Director of this organization, a position which is a highly visible, highly paid

position in most societies. Ross and his lovely wife Sharon have handled all of membership applications, renewals, all financial matters, most organizational follow-up including overseeing plans for annual meetings, Executive Committee meetings, as well as reminding the members of the Executive Committee of assignments and commitments that had made.

When the society organized, the members decided to publish a formal scientific publication. This effort was spearheaded by Dr. J. Donald Harris and appeared as the *Journal of the American Audiology Society* and changed to the *Journal of the American Auditory Society* in 1978 with the society name change.

In 1980, Ross Roeser took over from Dr. J. Donald Harris as the Society's Editor in Chief. Ross introduced a new name, *Ear and Hearing*, and a new philosophy and format that have resulted in a Journal that has assumed a place of national and international prominence. As Dr. Robert Keith states, "The success of our Journal is largely due to the vision and guidance of this talented man and his efforts are due to respect and gratitude of our clinical and scientific community who have benefited from his work."

Ross Roeser, for all your efforts in our behalf, Secretary-Treasurer for over 12 years, Associate Editor, *Corti's Organ* 1976-1984, member, Editorial Policy Board of the *Journal of the American Auditory Society* 1975-1979 and, last but certainly not least, as Editor in Chief, *Ear and Hearing*, 1979-1985, the membership of the American Auditory Society salute you and honor you.

Mike Seidemann presents award to Ross Roeser after roasting him with the aid of graphic slides.

Keith Asks AAS to SHARE Their Knowledge

The primary purpose of SHARE (Speech and Hearing Alliance for Resource Exchange) is to assist in the international development of Audiology and Speech Language Pathology training programs and services through the sharing of surplus textbooks, journals, reprints or other materials and resources.

based on this information, a budget would be generated.

There being no further business the meeting was adjourned.

Ross J. Roeser, Ph.D.
Secretary, Treasurer

A secondary purpose is to share experiences and information among persons with the common interest of helping the communicatively impaired.

The primary recipient of these resources will be training or clinical programs located in developing nations who do not have the means to purchase journals and textbooks necessary for the development of professionals who will serve the communicatively handicapped in their countries.

The method used for obtaining books, journals, and other materials will be through donations from individuals and libraries. Although more recent editions of textbooks are more useful, any edition can be helpful as background information for beginning scholars and as

Editorial Board Working Hard

Date: Sunday, October 20, 1985, 10:00 a.m., Atlanta, GA
Present: Robert W. Keith, Hiroshi Shimizu, Deborah Hayes, Eugene Sheeley, Don Worthington, J. Gail Neely, Laszlo Stein, and Ken Startt from Williams and Wilkins Publishing Co.

A continuing problem with scheduling is that there is not sufficient backlog of accepted manuscripts. Since May, 1984, approximately 53% of submitted manuscripts have been accepted, 39% rejected, and 13% returned to the author (s) for revision. Ken Startt from Williams and Wilkins stated that a rejection rate of 40 - 60% is appropriate for *Ear and Hearing*. At present, 24 manuscripts are out for review, 18 are awaiting revision, and 8 have been accepted for publication. Dr. Keith stated that manuscripts returned to author (s) for revision are held for 6 months and will not be sent for second peer review if the revisions are satisfactory. After 6 months, the manuscript will be considered new and will be subject to the entire editorial process.

In addition, *Ear and Hearing* was allotted additional pages, and the journal pages are underutilized. This adds to the problem of not having sufficient backlog.

Fred Bess is scheduled to have a special issue on unilateral hearing loss for Vol. 7, No. 1 (Jan/Feb), 1986. Dr. Bess is also scheduled to edit a supplement for the July/August issue, which will focus on the papers presented at meeting dedicated to Jay Sanders.

The March/April issue will feature eight manuscripts plus Dr. Sheeley's software directory and the Book Review Section.

The May/June issue will be a special issue on ENG, edited by Dr. Neely. Twelve authors include Dave Lilly, Tom Balkany, Alfred Coats, Kevin Kavanagh, Paul Lambert, John Dickens, Keith Clark, and Barry Hirsch. Topics will focus on the dizzy adult patient, the dizzy child, ENG techniques, errors and artifacts, peripheral lesions, non-localizing lesions, and torsion swing. It is hoped that his special issue will be used as a manual on ENG and will be a valuable teaching tool. It is hoped that these special issues will create a backlog of accepted

manuscripts.

Dr. Worthington reported that many otolaryngologists with whom he has been in contact seem to consider EH to be a journal just for audiologists. He would like to see more otolaryngologists become active members of AAS and submit their manuscripts to EH.

Dr. Neely suggested that speakers who present at various meetings be personally contacted with regard to the possibility of publishing their paper in EH. An incentive would be to offer publication within four months, but manuscripts would still be subject to peer review and must be appropriate for the readership. There was some discussion regarding the appropriateness of approaching these individuals for the purpose of soliciting their manuscripts. There was no objection to begin this practice.

Dr. Neely is willing to contact otolaryngologists, audiology/otology teams, and department chairpersons to solicit case studies, unusual cases, etc., stating that there is a lot of good, unpublished data. Dr. Neely is interested in receiving manuscripts from physicians on such topics as SICU monitoring, or monitoring psychoacoustics, approaches to differential diagnosis, early identification, medical aspects of congenital hearing loss, etc.

The journal philosophy was discussed. The majority of EH manuscripts are related to hearing aids/aural rehab (approx. 20%-25%). We would like more manuscripts dealing with diagnostic approaches and psychoacoustics of auditory pathology.

The breakdown of subscribers is:

- 500 US libraries
- approx. 1700 members
- 600 non-members
- 125 students
- 300 overseas (mostly libraries)

Adding a new section to the journal entitled Grand Rounds of Audiology or a case studies section was discussed. It was the opinion of the board not to add another section. We could devote one page to a single case that would have teaching value and do that through the clinical notes sections.

The time element of 8-10

Continued on page 5

1983 and 1984 Ear and Hearing Editor's Award Recipients Announced

At the 1985 meeting of the American Auditory Society, held in Atlanta on October 21, the 1983 and 1984 *Ear and Hearing* Editor's Awards were presented. The recipients were selected by the entire Editorial Board. Several papers nominated by the Board were judged according to their scholarly merit and their impact within the field. Awards were presented for both 1983 and 1984 because an Executive Committee discussion of the award's status delayed the 1983 presentation by one year.

For 1983 two papers were selected: "Auditory Brainstem Response Variability in Infants" by Janet E. Stockard, James J. Stockard, and Ronald W. Coen, and "Neural Correlates of Sensorineural Hearing Loss" by Richard J. Salvi, Don Handerson, Roger Hammernick, and William Ahroon.

For 1984 three papers by the same authors on the same topic were selected by the committee: "Application of Clinical Decision Analysis to Audiological Tests" by Robert G. Turner and Donald W. Nielsen; "Clinical Performance of Audiological

and Related Diagnostic Tests" by Robert G. Turner, Neil Shepard, and "Formulating and Evaluating Audiological Test Protocol" by Robert G. Turner, Gregory J. Frazer, and Neil T. Shepard.

In presenting the awards, Ross J. Roeser, Ph.D., retired editor of *Ear and Hearing*, expressed his satisfaction with the excellent quality of material that is being submitted to the journal.

Richard Salvi accepts The *Ear and Hearing* Editors Award from Ross Roeser with pride.

Robert Turner accepts the 1984 *Ear and Hearing* Editors Award for three papers on Clinical Decision Analysis in Audiology

1985 American Auditory Society Meeting Available On Videotape

The 1985 annual meeting of the American Auditory Society was videotaped and will be made available to members in January 1986. Michael F. Seidemann, Chairman of the Audio-Visual Committee, provided his expertise in preparing this material for the society. A formal announcement of the availability of the videotape will be made early in 1986. Those interested in more information should contact:

Michael F. Seidemann, Ph.D.

Lipscomb Announced as '85 Beltone Distinguished Teaching Award in Audiology Winner

David M. Lipscomb, Ph.D., a professor and director of the Noise Research Laboratory at the University of Tennessee, Knoxville has been named the winner of the 1985 Beltone Distinguished Teaching Award in Audiology (BDTAA).

The BDTAA is the only teaching award given in the field of audiology. It was initiated by Beltone Electronics Corporation, the nation's largest manufacturer of hearing aids and hearing test instruments, to recognize contributions made by the teaching profession in the field of audiology. To be eligible, instructors must be nominated by a current or former audiology student and have five or more years of experience in teaching audiology.

Lipscomb has been an audiology instructor for more than 25 years. He is a leading authority on the effects of environmental noise on man. He is also well known for his research on industrial audiology and the physiology of the ear. He is on the board of directors of the Better Hearing Institute and the executive board of the American Auditory Society. Lipscomb was named a fellow of the American Speech-Language-Hearing Association in 1973. A charter member of the Southern Audiological Society, he also served as the organization's president in 1974. He has published dozens of technical and non-technical articles and has authored five books and 12 chapters in books. A sought-after speaker, he has lectured at 50 professional workshops and seminars, delivered papers at 24 conventions and given more than 350 presentations to schools, service clubs and other organizations.

As the 1985 BDTAA winner, Lipscomb receives a \$1000 cash award, a commemorative plaque and a luncheon in his honor at the University of Tennessee from Beltone. He also has the opportunity to deliver three Beltone-sponsored lectures at different universities across the country.

In addition, Beltone awards the University of Tennessee, Knoxville, a \$2500 scholarship to assist with the education of an audiology graduate student. A \$100 award is given to the students who nominated Lipscomb.

Lipscomb was chosen from a field of 16 candidates. His required essay on "The Future Role of the Audiologist in the Healthcare Field" was one of seven factors weighed by a blue-ribbon panel of judges. The panel was composed of 10 prominent professionals in the field of audiology—including two previous BDTAA winners -- plus one student representative chosen by the National Student Speech-Hearing-Language Association.

The judges were Charles I. Berlin, Ph.D. (1984 winner), Louisiana State University; Fred Bess, Ph.D., Vanderbilt University; Michael R. Chial, Ph.D., Michigan State University; Marion R. Downs, M.A., University of Colorado; Gloria Garner (student), University of Georgia; Jack Katz, Ph.D., State University of New York; Bob Keith, Ph.D., University of

Members Absent: Charlie D. Anderson, Suzanne Brown, Earl Harford, E. Robert Libby, William L. Mayerhoff, James A. Nunley, Wayne J. Staab, and W. Dixon Ward.

Guests: Patrick E. Brookhouser, Barry Freeman, Alison M. Grimes, David J. Lilly, Richard T. Miyamoto, William F. Rintelmann, Hiroshi Shimizu, Eugene Sheeley, Ke Startt, Laszlo K. Stein.

1. President Worthington, **opened the meeting** at 1:22 p.m.

2. President Worthington welcomes the **new Executive Committee members** attending the meeting. They were Patrick E. Brookhouser, Alison M. Grimes, David J. Lilly, Richard Miyamoto, William F. Rintelmann, and Laszlo K. Stein.

3. The **minutes from the 1984 meeting** of the Executive Committee were reviewed and approved.

4. The **Treasurer's report** for the period 1/85 through 9/85 was reviewed by Ross Roeser. There were no comments.

5. Ross Roeser gave a **report on membership**. The current 1985 membership as of 9/30/85 was 1,686. This represents approximately 130 more members than 1984. Of the 1,686 members, 1,470 (87%) are audiologists, 6 are engineers / industry representatives, 39 (2%) are hearing aid specialists, 149

Cincinnati; Geary McCandless, Ph.D., University of Utah; Frank E. Musiek, Ph.D., Dartmouth-Hitchcock Medical Center; Ralph R. Rupp, Ph.D., University of Michigan; and Terry L. Wiley, Ph.D. (1983 winner), University of Wisconsin.

The result of this year's Beltone Distinguished Teaching Award in Audiology Search was officially announced on October 21 at the annual meeting of the American Auditory Society in Atlanta, GA.

Beltone Electronics distributes its products through a network of trained and authorized hearing aid specialists at more than 3300 locations in the U.S. and Canada. The company has produced more than 2 million hearing aids since it was founded in 1940.

(10%) are physicians, and 22 (1%) are associate members. The special membership offer sent by the Promotional Committee generated 292 new members for 1985 and 95 new members for 1986.

6. A discussion was held regarding the possibility of establishing a **student resident membership category**. By opening up this membership category it would give students and residents an incentive for joining the Society. Following the discussion a motion was made to create a student/resident special membership rate of \$20.00. This motion passed. Members requesting this form of membership will have to have their student/resident status verified by an official representative in their university.

7. David Lipscomb reported on the **1985 meeting**. He thanked his committee members and gave special recognition to Mike Seidemann for his work. This year there were far many more submitted papers than could be considered for presentation. Based on his, he suggested that the possibility of having either two meetings per year or parallel sessions be considered. After discussion it was decided that neither of these two options was possible.

8. Bill Rintelmann discussed plans for the **1986 meeting** in Detroit. He said that there were 10 members appointed to his committee. The meetings will be held at Wayne State University. The Carhart Speaker was identified and LaVonne Bergstrom will be responsible for contacting him to verify his participation.

9. Chicago was chosen as the site for the **1987 meeting**. Laszlo Stein was voted the Chairman for that meeting.

10. The Chairman of the **19th International Congress of Audiology** for 1988, Moe Bergman, contacted Don Worthington to find out if the American Auditory Society would be willing to meet in Jerusalem, Israel during that congress. After discussion, a motion was made that AAS retain the format of alternating the annual meeting between ASHA and AAO/HNS. The motion passed. As an alternative it was suggested that Don Worthington contact Moe Bergman and ask if it would be possible to have a special session that the International Congress meeting devoted to papers presented by members of the American Auditory Society.

11. Ross Roeser was **appointed Secretary/Treasurer** for 1987.

12. **Suzanne Kos** was made an ex officio member of the Executive Committee and appointed **Assistant Secretary** for 1987.

13. Robert Keith gave a report on **Ear and Hearing**. The section editors and the reviewers of manuscripts were thanked for their participation. During 1985 a total of 85 manuscripts were submitted. The acceptance rate was 52%, with 32% of the manuscripts rejected and 16% waiting for revision. In 1986 the January - February journal will be a special issue on unilateral hearing loss edited by Fred Bess. The March-April issue will include a computer software directory by Eugene Sheeley and several letters to the editor regarding the cochlear implant supplement. The May - June issue will be a special issue on electronystagmography. In the July-August issue there will be an essay tutorial on testing in the surgical intensive care unit by Jay Hall and a mini series on neuroanatomy by Frank Musiek. The September - October issue may be a supplement. The special issues have been scheduled in an attempt to create a backlog of accepted manuscripts that will help the scheduling process.

Dan Schwartz resigned as the section editor for hearing aids. Dr. Keith expressed his deep gratitude for Dr. Schwartz' contribution in the past year. A new section editor has been identified. (Subsequent to the meeting, Lou Beck was contacted and accepted the post as section editor for hearing aids beginning in January 1986.)

A new reference style will be started with the January-February issue. Also, a new thrust in the journal will be to attempt to get physicians as readers. New sections in the journal will include a calendar of events and letters to the editor.

Ken Startt reported on the financial condition of **Ear and Hearing**. He said that his company is very pleased with the progress that the journal has made. 1984 paid circulation reached an all time high of 2,848 subscribers, a 15% increase over 1983. Paid circulation for 1985, as of September 30, was 3,079 subscribers. Prospects for continued growth in 1986 are excellent. The page allowance for 1985 and 1986 is 400 text pages. Member subscription price will remain the same (\$23.00) for 1986, and most likely will not change for 1987. The journal will generate a profit for 1985, which will be used to pay off the accumulated deficit. With the current growth of the journal the accumulated deficit will be paid in 1986, and a profit should be made, which will be split 50-50 with the American Auditory Society.

14. Joe Rizzo, Executive Director of the Better Hearing Institute, presented on BHI. He indicated that he would welcome the participation of the American Auditory Society in sponsoring a public service

announcement through BHI. The cost of this public service announcement is about \$20,000.00.

15. A discussion was held on **Corti's Organ**. Suzanne Brown was not able to attend the meeting and suggested that consideration be made to replace her as the editor. After discussion, an individual was identified. (Subsequent to the meeting Virginia Anderson Berry was contacted and she accepted the appointment. Suzanne Kos was named assistant editor.)

16. Ralph Naunton gave a report on the Long Range Planning Committee. He reviewed the history of the committee and recapped the activities of the committee. He was his recommendation that the Long Range Planning Committee be formalized, specific number of members be identified, and work begun on formulating long range commitments for the Society. These concepts were supported and it was decided that the committee have four members on it. Ralph Naunton was appointed as the Chairman and David Lilly was appointed a member from the Executive Committee. Other committee members will be appointed the Chairman.

17. Mike Seidemann gave a update on the **Membership Promotional Committee**. During 1985 three activities were conducted. A direct mail to ASHA audiology members and members of AAO/HNS participation in the Run for Better Hearing, and having a display at the annual meeting of AAO/HNS. After discussion was the decision to add especially otolaryngology and the hearing aid industry. Through offering a student/resident category of membership it was felt that membership from these two segments will be increased. Mike Seidemann will remain the Chairman of the Membership Promotional Committee for 1986.

18. Suzanne Kos reported on the **Committee for Qualifications**. She presented 3 lists of members. Following review by the Executive Committee all applicants were accepted for membership. (The names of those accepted appear at the end of the minutes.) Suzanne Kos was reappointed as the Chair of the Qualifications Committee.

19. LaVonne Bergstrom reported on the **Carhart Speaker Committee**. She indicated that Dr. Joseph Hawkins has been contacted and has accepted the invitation for 1986. Following this, the Executive Committee members suggested several possible members of the committee are: E. Robert Libby, Don Worthington, and Patrick Brookhouser.

Worthington, and Patrick Brookhauser.

20. Mike Seidemann reported on the **purchase of the video equipment**. He described the equipment, which represents a capital outlay of approximately \$2,000.00. The entire proceedings of the 1985 meeting, as well as all future annual meetings, will be videotaped and offered to members. Seidemann stated that he had already received about 25 orders for the Gunar Liden tape, and that sale of this tape has generated an income of about 20% of the capital outlay for the equipment.

21. Don Worthington reported on the **joint committee on infant hearing**. He said that he had written a letter requesting representation for AAS on the committee. That request was reviewed by committee members in July and the response indicated that they were concerned about over balancing the committee with one discipline, i.e., audiologists, otolaryngologists, etc. In addition, they had received requests from other groups for inclusion. It was their decision to not create a committee that was unmanageable. They recommended to their parent organizations (ASHA, AAO/HNS, etc.) that the committee have one main committee with voting members then add consulting organizations (of which AAS would be one) that would give input but not allowed to vote on issues. This recommendation was sent to the ASHA Executive Board for consideration. The Executive Board of ASHA turned it down and recommended that AAS not be included.

22. Don Worthington reported on the **Beltone Teaching Award in Audiology**. He indicated that this year the Beltone Award would be presented by the president (D. Worthington). This is the protocol that was adopted at the 1984 meeting of the Executive Committee. Because there may be a conflict of interest, he indicated that in the future, if Beltone or any other organization requests to have their award presented at the AAS meeting, that the president be authorized to delegate the responsibility to another Executive Committee member.

23. Don Worthington reported on the **OSHA Hearing Conservation Amendment Case**. He stated that in 1984, three judges from the Fourth Circuit Court voted 2 to 1 to vacate the OSHA Hearing Conversation Regulation. They concluded that the amendment exceeded OSHA's authority by making employers responsible for hearing loss incurred outside the workplace. The Department of Labor and OSHA filed a petition for review of the case by the Court of Appeals for the Fourth Circuit.

To support the appeals case, American Speech - Language - Hearing Association (ASHA), along with the American Auditory Society, Academy of Dispensing Audiologists, Academy of Rehabilitative Audiology, etc. requested leave of the Court to appear as Amici Curiae.

The Amici Curiae was prepared

by ASHA, reviewed by three executive committee members from AAS and filed. The case was argued and material presented on June 3, 1985. On September 23, 1985, the Fourth Circuit Court of Appeals unanimously reversed the decision of the three judge panel.

24. Don Worthington reported on the former **Medical Audiology Society** donation. The past president of the Medical Audiology Society had contacted Charlie Anderson as President of AAS in 1982 concerning monies that had been left in their treasury that they were considering donating to the American Auditory Society. However, no closure had been made on this issue. In an effort to determine where this matter stood, President Worthington contacted Sharon Graham, a former officer of the Medical Audiology Society. She reiterated the fact that there was money in the treasury but indicated that it would take a vote of the full membership to donate it to any group. She stated that she would follow up this matter with former members and see what their desires would be. Once Sharon Graham reports back to Don Worthington he will inform the Executive Committee of the final decision.

25. Deborah Hayes reported on **Continuing Education Units**. She indicated that she had investigated CEU's from several organizations. It was clear that it would be possible to get CEU's, but no arrangements were made for the 1985 meeting. It was recommended that for the 1986 meeting AAS obtain CEU's from ASHA, CME's from the AMA, and approval from the National Hearing Aid Society.

26. The possibility of having a **hospitality suite at ASHA** was raised by Don Worthington. After discussion it was decided that we should attempt to meet at ASHA. Don Worthington indicated that he would pursue this.

27. Dareld Brackmann requested time following this year's annual meeting to discuss attracting more **audiologists involved in AAO/HNS**. This request was granted.

28. David Lipscomb discussed the possibility of having **workshops at the annual meetings**. Since there was a scheduling problem already with the annual meeting, one suggested was of accomplishing this was to alternate a workshop with ASHA or AAO/HNS meetings. Another possibility was to co-sponsor a workshop with another institution. This item was referred to the Long Range Planning Committee.

29. Alison Grimes reported on the possibility of participating in the **Council for Better Hearing and Speech Month**. She had attended a meeting earlier in 1985 as a representative of the American Auditory Society. She indicated that the Council is actively seeking new members. There are two types of membership-sponsor, costing \$800.00 annually and giving a voting privilege, and cooperating group, costing \$400.00 and having no voting privilege. The advantages and disadvantages of joining the Council were

Executive Committee At Work and Play

The AAS Executive Committee worked feverishly against the clock to deal with the 26 items on the agenda, each potentially deserving of a full day's attention. It is well known to veteran committee members that a unique dining experience awaits them at the end of their labors. They are, therefore, motivated to accomplish this formidable task within the allotted time. The minutes are printed herein to inform you of the Society's accomplishments.

This year's gastronomic delight, reminiscent of a popular 1960's fad, was fondue served at Dante's Down the Hatch on the Poop Deck!! Dante himself met us at the metro subway station in a vintage firetruck and wheeled us rather precariously to his restaurant. There socializing and dining took place in a maritime setting amid alligators, turtles, moats and old sailing sloops. Becky and Tad Zelski are to be complimented for these arrangements.

discussed and following that a motion was made that the American Auditory Society participate in the Council for Better Hearing and Speech Month beginning with the May 1987 campaign. This motion passed. A second motion was made to appoint Alison Grimes as the representative from the American Auditory Society to the Council. This motion passed.

30. Ross Roeser indicated that a **bequest of \$5,000.00** had been made to AAS by the Crystal Leon Elliott Sharp estate. The bequest was made specifically for the study and research for a cure for the hard of hearing, not deafness. After discussion it was the decision that the Long Range Planning Committee study ways in which this money could be used most effectively for its intended purpose.

31. Robert W. Keith presented information on a **project to send outdated publication materials** to underdeveloped countries. He asked members of the American Auditory Society to submit materials to him and he would insure that they would be sent to deserving countries. A full description of this program will be published in **Corti's Organ**.

32. President Worthington expressed appreciation to the following **departing Executive Committee members**: Charlie Anderson, Earl Harford, William Meyerhoff, James Nunley, and W. Dixon Ward.

33. There being no further business the meeting was adjourned at 5:32 p.m.

Don W. Worthington, Ph.D.
President

Ross J. Roeser, PhD.
Secretary/Treasurer

Continued from page 3

weeks in the Information for Authors was discussed. Dr. Shimizu questioned whether or not revisions should be handled directly by the section editor. It was decided that if the matter could be handled more efficiently and if it would reduce turn around time, then the section editor should correspond with the author(s). This is true especially in the case of minor revisions. It seemed that manuscripts that required major revisions should be handled by mail, since reviewers tend to have many specific comments and the author(s) would greatly benefit by having the reviews on hand.

Basic science papers, although few are submitted, should be evaluated on merit and should be published when appropriate. Publication of this type of paper will add prestige to the journal and possibly make it more competitive.

It was announced that Dan Schwartz resigned as section editor of the hearing and aural rehab. section because of an extremely busy schedule. Lucille Beck and Gerald Studebaker were suggested as replacements. A brief discussion of their qualifications was held. It was finally decided that Dr. Beck be offered the position. Dr. Keith will contact her. Dr. Keith expressed his deep appreciation to Dr. Schwartz for his contributions to the journal over the past year.

There does not appear to be a wide range of referees who are used as reviewers. Everyone was encouraged to expand their list of reviewers.

There is no mandate that requires the section editor to use two reviewers for manuscripts. The opinion of the section editor and one other reviewer is sufficient, if warranted.

Letters to the editor will begin in the March/April issue. This will be announced in the highlights of forthcoming issues. The first letters to the editor will be in response to the cochlear implant supplement. A disclaimer will be published in future special issues indicating that the articles are not peer reviewed and the editor of that supplement is not responsible for content.

The 1986 issues of EH will include a calendar of meetings and upcoming events.

Because referencing and style has been a problem in the past, the Uniform Requirements format was adopted and will take effect with Vol. 7, No. 1, 1986. The Uniform Requirements brochure was distributed.

Reverse color for the cover (green on white) for supplement was discussed. Ken Startt will investigate this possibility.

Dr. Sheely requested subject areas for book reviews. He will also invite other individuals to critique new books. Dr. Sheely usually initiates the request to the publisher but some books are automatically sent. He has some difficulty obtaining new medical books and asked for assistance in this matter.

Dr. Neely was thanked for his active role as the otologist member of the editorial board. Similarly, all members of the editorial board were thanked for their help during the past year.

With no other agenda, the meeting was adjourned.

graduates must be considered as perhaps the greatest contribution made by Dr. Carhart.

It has been my privilege to be acquainted with, and in some cases, to have worked with many of these individuals. One of the first that I met was Leo Doerfler, who was at Deshon even before Dr. Cahart and who later completed his doctoral work at Northwestern. Dr. Doerfler, Director of the Audiology at U. of Pgh. for over 25 years, has in turn been an outstanding teacher and contributor to the field of audiology. I am indebted to him for reviewing and improving my comments about the Deshon era. Also at Deshon, I made the acquaintance of Francis Sunday, later a doctoral graduate of Northwestern and Director of Audiology at Indiana University Medical Center. One of Dr. Sunday's duties at Deshon was to make earmold impressions using dental plaster, the standard method at that time. Much of the electronics work for Dr. Carhart at Deshon was done by the late Kenneth Stewart, who became a professor at the University of Pittsburgh. The Doerfler-Stewart test for malingering was developed at Deshon.

It would be difficult to name all of the individuals who studied under Ray Carhart with whom I have had the good fortune to be acquainted. To mention just a few, they include Don Dirks, Earl Harford, Jim Jerger, Roger Kasten, Wayne Olsen, Tom Tillman and Laura Wilber. Most of these have been active in Standardization work.

An interesting connection that I had with Ray Carhart was that my very competent secretary for several years before I retired, Jean Owens, had done secretarial work for Ray at Deshon.

Ray Carhart's greatest concern at Deshon Hospital, back in the forties, was to match the performance of a hearing to the needs of a hearing impaired individual. We have seen a great deal of progress since then, particularly in the direction of measuring the performance of an aid on a person and in the direction of protocols relating the required performance of a hearing aid to an individual's hearing characteristics. Equally important are the great strides that have been made in hearing aid technology.

The coupler measurement of a hearing aid has proved essential, first, because it provides accurate, repeatable data on the operation of an aid and second, because the data are available on all aids sold in the U.S. as the result of FDA regulations. Thus, the coupler measurement can well be the starting point for the selection of an aid for a particular type and degree of hearing impairment.

A full description of procedures to obtain hearing aid performance data, using the standard 2cc coupler, is contained in American National Standard S3.22-1982, available from the Acoustical Society of America. A basic measurement setup for testing hearing aids is shown in Fig. 1. A loudspeaker delivers the desired sound pressure level (SPL) at the microphone opening of the hearing aid. This input SPL is accurately measured by a calibrated standard microphone placed close to the microphone opening on the aid. The output of the standard microphone is

fed back to a compression circuit in the pure tone oscillator supplying the loudspeaker and a constant SPL at the microphone opening is maintained. The acoustic output of the hearing aid is fed to a standardized 2cc coupler via a specified tubing connection. In the case of an in-the-ear or in-the-canal, the tip of the aid that projects into the ear canal is placed flush with the reference plane (outer cavity surface) of the 2cc coupler and the aid is sealed in place with modeling clay or similar material. Fig. 2 shows these two coupler arrangements. The SPL developed in the coupler is then automatically recorded as a function of frequency. In addition to a basic test system such as that shown in Fig. 1, test equipment of modest size can be used to make accurate tests on most kinds of aids and to produce printouts of the data. Much more complex systems using computerized control are also employed.

It is well known that 2cc measurements, particularly those of frequency response, may not give the best indication of the results that will be obtained on a person. A better indicator of what the aid does on a person is given by its insertion gain. (or response).

Technical portion 1

To review the concept of insertion gain, first look at Fig. 3. A sound source is delivering a suitable constant sound pressure level L_0 at a test point in a non-reflective space. In Fig. 4, a head facing the source has its center at the test point. A hearing aid amplifies the sound and produces a sound pressure level L_3 at the eardrum. In Fig. 5, the hearing aid is removed and the sound pressure level at the eardrum is L_4 . A plot of the results is shown in Fig. 6. The flat 60 dB SPL line shows the SPL at the test point with the head absent. The solid upper curve is the SPL produced at the eardrum when the hearing aid is present. The dashed line is the SPL at the eardrum with the ear canal open and no hearing aid present. The dotted curve shows that there is considerable amplification without the aid due primarily to ear canal resonance. The increase in SPL at the eardrum for the two conditions is the insertion gain, the amount the hearing aid really adds. Note that the effect of ear canal resonance and other factors is small at low frequencies, but very significant from 2 to 5 kHz.

The insertion gain (or response) of a hearing aid compares well with functional gain or response as measured subjectively and is a good indicator of how the hearing aid will amplify sound for the user.

Insertion gain is influenced by the direction of incidence of the sound. For standardized in-situ tests, 0° incidence, with the sound source a meter away, is used. This corresponds roughly to the position of a person speaking directly to the listener. It is also possible to derive the insertion gain for random incidence, as has been suggested by Killion and Monser (1980). This would correspond to a situation where the speaker was farther away and located in a fairly reverberant space. In addition to the direction of arrival of sound, the position of the

Figure 5. Head in sound field without a hearing aid.

Figure 6. Insertion gain of a hearing aid.

Figure 7. Head and sound source with hearing aid. L_0 is the SPL with the head absent. L_1 is the SPL at the sound entrance of the hearing aid microphone.

Figure 8A, 8B, 8C and 8D. Level relationships for conditions shown in Figs. 7, 9, 10 and 11.

Figure 9. Hearing aid in place on head, but output delivered to a 2cc coupler. L_2 minus L_1 is the 2cc coupler gain of the aid.

Figure 10. Hearing aid delivering output to the eardrum or ear simulator. L_3 minus L_0 is the apparent gain of the aid without considering natural amplification of the ear.

hearing aid microphone sound entrance effects insertion gain.

Three methods by which the insertion gain available from a hearing aid can be found are:

1. Direct measurement of the sound pressure level in the ear canal of a person by means of a probe tube or canal microphone near the eardrum, with and without the hearing aid.

2. Measurement with and without a hearing aid on a carefully dimensioned manikin such as the Knowles KEMAR. The sound pressure level at the equivalent of the eardrum location is measured by a calibrated microphone in an ear simulator.

3. An estimated insertion gain derived by applying a correction to the standard 2cc coupler gain or response curve.

Method 1 can now be accomplished with sophisticated probe tube equipment. Its application is perhaps best suited for checking in-situ performance and making adjustments after suitable hearing aids have been selected.

Method 2 has been very successfully used for hearing aid selection by the Veterans Administration for several years. It requires expensive equipment and good expertise.

Method 3 appears to have considerable practical value, since an approximation of the corrections needed can be derived and applied to the gain or response curves supplied with every aid sold in the U.S. in accordance with FDA labeling regulations. Currently, no standardized correction have been established, although the possibility is under consideration by standards Working Group S3-48. If such standardization were to prove feasible, manufacturers might be willing to voluntarily add an estimated insertion response curve that could make aid selection easier.

In addition to the use of manikin tests on particular hearing aids to derive an estimated insertion response, it also possible to obtain a useful estimated correction to apply to 2cc measurement data. This is done by adding to the 2cc coupler response a head baffle correction and the 2cc coupler-to-ear simulator correction and then subtracting the free field-to-eardrum transformation.

In Fig. 7 is shown a diagram of a head and sound source. The electrical input to the sound source is adjusted to produce a sound pressure level L_0 , constant with frequency, at a chosen test point when the head is absent. The SPL at the hearing aid microphone sound entrance, L_1 , is different than L_0 because of the presence of the head. The difference ($L_1 - L_0$) is the head baffle effect. Fig. 8A shows this effect for a typical OTE sound entrance location (at the pinna notch) and for an ITE aid with the sound entrance at the center of the filled concha. The curves are based on KEMAR measurement made by Madaffari (1974). Different corrections would be needed for in-the-canal aids or others with different sound entrance locations.

Fig. 9 shows the same OTE aid in place, but with its acoustic output directed to a 2cc coupler through the identical acoustic connection used to the ear canal. An SPL L_2 is developed at the

condenser microphone in the 2cc coupler. By definition, ($L_2 - L_1$) is the standardized 2cc coupler acoustic gain, available from specific accompanying all hearing aid and indicated in Fig. 8B.

In Fig. 10, the 2cc coupler has been removed and the earmold placed in the ear canal where it generates an SPL L_3 at the eardrum position. Sack and Burkhard (1974) developed an average relationship between the SPL at the eardrum of real ears and that produced in a 2cc coupler for typical hearing aid receivers with identical acoustic tubing connections. Fig. 8C shows this average relationship, which is also the same as that between closed ear simulator and closed 2cc coupler. The increase in the SPL at the eardrum compared to that at the 2cc coupler is ($L_3 - L_2$).

In addition to direct measuring L_3 , we can also arrive at a value for it by adding the various corrections to the free field SPL L_0 . Thus,

$$L_3 = L_0 \pm (L_1 - L_0) \pm (L_2 - L_1) \pm (L_3 - L_2) \text{ Eq. 1}$$

One might assume that the useful gain of the hearing aid is simply ($L_3 - L_0$). However, we must take into account the natural gain of the ear as indicated in Fig. 7. With a free field SPL of L_0 and no hearing aid, a sound pressure level L_4 will be produced at the eardrum. The average relationship between L_0 and L_4 has been carefully examined by Shaw (1974) (also Shaw and Vaillancourt, 1985). For coincidence, the curve of Fig. 8D shows this relationship. The amplification due to ear canal and concha resonance and head effects is ($L_4 - L_0$). To get the insertion gain, this must be subtracted from the apparent gain ($L_3 - L_0$).

$$IG = (L_3 - L_0) - (L_4 - L_0) = (L_3 - L_4) \text{ Eq. 2}$$

$$\text{or } IG = L_0 \pm (L_1 - L_0) \pm (L_2 - L_1) \pm (L_3 - L_2) - L_4 \text{ Eq. 3}$$

$$\text{Rearranging terms, } IG = (L_2 - L_1) \pm (L_1 - L_0) \pm (L_3 - L_2) - (L_4 - L_0) \text{ Eq. 4}$$

Eq. 4 says: insertion gain = 2cc coupler gain \pm head baffle effect \pm 2cc-to-ear simulator correction - free field-to-eardrum transformation.

Thus $IG = 2cc \text{ coupler gain} \pm K$, where K is the sum of the last three terms above.

Calculated values for K are shown in Fig. 12 (upper). The solid curve is for an OTE aid; the dotted curve is for an ITE aid. This curve is for an OTE aid; the dotted curve is for an ITE aid. These curves show the corrections that must be applied to a 2cc coupler gain or response curve to get an estimated insertion gain or response curve.

An alternate way to look at this situation is shown in the lower curves, which are the negative of the upper curves. These show the curve shape needed, as measured using a 2cc coupler, to produce a flat, zero gain, insertion response. This type of curve has been termed CORFIG (for coupler response for flat insertion gain) by Killion and Monser (1980). It can be seen from the CORFIG curve that an OTE aid should have a substantial peak at about 2700Hz to give a smooth insertion gain curve. Less of a peak would be indicated for an ITE aid, as indicated by the dotted curve.

Preliminary calculations, requiring further confirmation, indicate that for an in-the-canal

shape will be almost the same as that of the 2cc coupler curve.

Fig. 13 shows how the performance of an OTE aid is affected by applying the correction of Gif. 12. The solid curve is the aid's 2cc gain curve. The dashed curve is the estimated insertion gain curve. The dotted curve is the same as the dashed curve but moved down to coincide with the 2cc gain curve at 100 Hz. The strong dip can be seen in the 2.7 kHz region. A smoother insertion gain curve would have been obtained with additional gain in this region, as measured on the 2cc coupler.

This is a point that should be remembered, because you can quickly visualize the nature of the insertion response by looking at a 2cc coupler curve and making a mental subtraction of about 10 dB in the 2.7 kHz region for an OTE aid, less for an ITE aid.

Considering the prevalence of increasing hearing loss with frequency, a flat insertion gain response would not be desired too often. Fig. 14 shows how the CORFIG values can be added to a desired final insertion response characteristic to obtain a 2cc coupler response estimated to produce it. The curves shown are for an OTE aid. The lower dashed curve shows a desired insertion gain characteristic rising at 3 dB/octave. The solid curve shows the broad peaking at 2.7 kHz.

The upper dashed curve shows a desired insertion gain characteristic rising at 6 dB/octave up to 2 kHz and then remaining flat above that. The adjoining solid line shows the estimated 2cc coupler curve that would be needed to produce it.

Some precautions must be observed in predicting an estimated insertion gain or response curve from 2cc coupler data, or vice versa, as follows:

1. The correction used must be for the type of aid used so as to take into account the location of the hearing aid microphone sound entrance.

2. Identical acoustic tubing connections must be used in the case of OTE and eyeglass aids. This is not a problem with ITE or ITC aids. The length, and particularly the inside diameter of tubing used in an actual fitting should be the same from the hearing aid to the tip of the earmold as was used in the 2cc coupler test. In many cases, the published curves are made with 25 mm of #13 tubing followed by 18mm of 3 mm diameter tube adjacent the coupler cavity. The effect of this dual tube arrangement is to enhance the 2cc coupler response by about 6dB from 2.2 to 6 kHz. If single diameter #13 tubing is to be delivered with the aid, the 2cc coupler response should be greater in this region than otherwise, or a dual diameter tubing arrangement such as a 3mm horn should be used.

3. While excellent for closed coupler tests over the usual hearing aid frequency range, the 2cc coupler is unsuitable for measuring the effects of venting because it produces a sharp peak at the vent resonant frequency not present in actual ears. The corrections or corfigs that have been discussed apply only to closed, unvented

conditions. Venting corrections should be handled separately. Data on various types of venting are given in Katz Handbook of Clinical Audiology (2nd or 3rd edition).

It is fully recognized that variations in ear size and ear canal impedance exist from one individual to another and that in some cases they are large. Studies made on real ear performance of hearing aids compared to 2cc coupler data have been made by Harford (1980), Hawkins and Haskell (1982) and Hawkins and Schum (1984). While estimated insertion gain or response using the methods described in this discussion will give a better guide to the selection of an appropriate hearing aid than might be obtained using only 2cc coupler data, the need for final evaluation on an actual user remains important.

We can improve our measurement and understanding of insertion gain or response by derivation estimates from the 2cc coupler data, by the use of KEMAR measurements or by direct probe-tube measurement on an individual. However, the most exact determination of insertion gain is of little value unless we establish a definite target for what we want-- and this is not so easy. A number of protocols for deriving the desired amplification and limiting have been developed and successfully applied. These protocols all aim to place the amplified signal level at some comfortable point within the dynamic range of hearing available to the hearing impaired person. Many of the systems used tend toward an amount of insertion gain roughly equal to half the pure tone hearing level over the frequency range of interest. Some of the procedures for determining suitable amplification characteristics from audiological measurements are those of Berger, Hagberg and Rane (1979), Brooks (1973), Byrnes and Tonisson (1976) and McCandless and Lyregaard (1983).

The following steps might be suggested to arrive at a suitable frequency response for a hearing aid:

1. Make audiological tests, including HTL and probably MCL.

2. Using a suitable protocol, determine the insertion gain desired over the frequency range. Allow some additional reserve gain.

3. Using 2cc coupler response data with corrections applied to give an estimated insertion response, select a hearing aid or aids that appear suitable. Some protocols have an insertion gain correction built in, so the 2cc coupler data can be examined directly.

4. Make a final in-situ check with the aid on the user by established audiological methods or perhaps by probe-tube measurements.

Of course, there are a lot of other factors to consider, such as various types of compression, limiting or signal processing that require attention as well as frequency response.

It is hoped that the material presented today will add in some small way to the many basic contributions made over the years by the man we are honoring today-- Raymond Carhart.

Thank you.
