Lifestyle hazards and secondary outcomes (Kidney Replacement Therapy, eGFR decline, and albuminuria)

Kidney

Replacement

A total of 17 studies encompassing 990,723 participants reported associations of lifestyle behaviours to KRT.

Therapy (KRT)

Diet behaviours: Six studies involving 701,627 participants reported associations of 13 different dietary factors to KRT. No meta-analysis was possible for any factor due to having less than 2 exposures for each diet factor, however 2 studies (100%) showed potassium intake and 1 study (50%) showed coffee intake to be significantly associated with decreased risks of KRT. In contrast, four diet factors were found to be potentially harmful to KRT, including protein, high red meat intake, sodium and diet beverages, with over 50% of studies reporting these outcomes demonstrating significant associations (see Supplemental Figure 1 and Supplemental Table 4).

Physical activity: Three studies involving 70,058 reported associations of physical activity to KRT. One of these studies reported a significant reduced risk of KRT, and another study reported a significant increase risk of a composite outcome of treatment of KRT due to any cause, or death related to CKD in people with higher levels of physical activity compared to lower levels. However, these results could not be pooled in meta-analysis and are therefore reported in Supplemental Table 4.

Alcohol consumption: Two studies involving 74,683 reported associations of alcohol consumption to KRT. One of the two studies (50%) reported significant reduced risk of KRT, however the results could not be pooled in meta-analysis and are therefore reported in Supplemental Table 4.

Smoking exposures: Eight studies involving 1,230,390 participants reported associations of smoking to KRT. Meta-analysis of all studies reporting a smoking exposure (ever smoked) compared to never showed a significant increased risk of KRT (RR 1.59 [95% CI: 1.30, 1.94];

I²=68%; Evidence quality: Moderate) (see Supplemental Figure 1). Meta-analysis also showed that former (not current) smokers compared to current was significantly associated with increased risks of KRT (RR 1.25 [95% CI: 1.13, 1.39]; I²=39%; Evidence quality: Moderate) (see Supplemental Figure 1).

GFR decline

Diet behaviours: A total of 22 individual studies involving 77,274 participants reported associations of 24 different dietary factors to eGFR decline. Only potassium and protein intake exposures were able to be pooled into meta-analysis. Higher potassium intake was associated with a significant decreased risk of eGFR decline (RR 0.49 [95% CI: 0.31, 0.79]; I²=90%; Evidence quality: Very low), whereas higher protein intake was not (Table 2; Supplemental Figure 2).

Twenty-two other dietary factors and their associations to eGFR decline were reported across 17 studies, which did not have enough data to pool into meta-analysis and are therefore descriptively reported in Supplemental Figure 1 and Supplemental Table 4. Of these, only magnesium and vitamin A intake were potentially protective against eGFR decline, with over 50% of studies indicating a protective relationship. In contrast, 5 diet exposures, including sodium, saturated fat, carbohydrate intake, sodium-potassium ratio and diet beverages had at least 50% of studies demonstrating a potentially harmful relationship to eGFR decline (Supplemental Figure 4 and Supplemental Table 4).

Physical activity: Seven studies involving 27,075 participants reported association of physical activity levels to GFR decline demonstrated a higher level of physical activity significantly reduced the odds of eGFR decline (5 studies; 15,161 participants; OR 0.77 [95% CI: 0.63, 0.93]; 75%; Evidence quality: Very low) (Table 2; Supplemental Figure 2). The results of the other two studies which could not be meta-analyzed concurred with this analysis, with 50% of the associations being significantly positive (Supplemental Table 4).

Alcohol consumption: Seven studies involving 28,494 participants reported no association of alcohol consumption to GFR decline (Table 2; Supplemental Figure 2).

Smoking exposures: No meta-analysis was possible for smoking exposures to GFR decline. Five studies reported smoking and associations to eGFR decline, with only 1 showing significant decreased GFR at follow up (Supplemental Figure 2; Supplemental Figure 4 and Supplemental Table 4).

Albuminuria

A total of 20 studies encompassing 512,403 participants reported associations of lifestyle behaviours to incident albuminuria.

Alcohol consumption: Seven studies involving 220,479 participants reported no significant association of alcohol consumption to incident albuminuria (Table 2; Supplemental Figure 3). Diet behaviours: Nine studies involving 36,642 participants reported associations of 19 different dietary factors to incident albuminuria. Only 1 meta-analysis was possible on sodium intake, demonstrating a non-significant increased odd of incident albuminuria (Table 2). Eighteen other dietary factors and their associations to incident albuminuria were reported across 9 studies, which did not have enough data to pool into meta-analysis and are therefore descriptively reported in Supplemental Table 4. Two diet factors, including fruit and dairy had at least 50% of studies demonstrating these to protective against incident albuminuria, whereas 5 diet factors, including, sugar-sweetened beverages, saturated fat, cholesterol, red and processed meat and energy intake had at least 50% of studies demonstrating a potentially harmful relationship to incident albuminuria (Supplemental Figure 3; Supplemental Figure 4

Physical activity: Four studies involving 110,154 participants reported a significant reduced odds of incident albuminuria (OR 0.88 [95% CI: 0.81, 0.96]; 0%; Evidence quality: Low) in people participating in higher levels of physical activity compared to lower levels (Table 2; Supplemental Figure 3).

and Supplemental Table 4).

Smoking exposures: Seven studies involving 184,302 participants reported associations of smoking to incident albuminuria. Meta-analysis of all studies of populations who had ever smoked compared to those who had never smoked showed a significant increased odds of

incident albuminuria (OR 1.67 [95% CI: 1.23, 2.26]; I²=88%; Evidence quality: Very low). There was no significant association in meta-analysis of former smokers compared to those who had never smoked, or former smokers compared to current smokers (Table 2; Supplemental Figure 3).

Subgroup analysis

A subgroup analysis by duration of exposure showed that physical activity and sodium intake exposures with durations less than 10 years to be more likely associated with lower risk of incident CKD compared with exposures greater than 10 years. In contrast, alcohol consumption and potassium intake exposures appeared to be associated with incident CKD when exposures were greater than 10 years, compared with exposures of less than 10 years. Sodium intake exposures were also more likely to be associated with lower risk of incident CKD in countries outside the US, whereas alcohol consumption was more likely to be associated with incident CKD in the US compared with other countries. Physical activity was not associated with incident CKD in the US or other countries. Studies reporting associations with incident CKD were also more likely to be significant if they reported associations using a risk ratio (RR) compared with an odds ratio (OR), including potassium intake, alcohol consumption and tobacco smoking. Other subgroup analyses either were consistent with the primary finding or were not possible because at least one subgroup had few than 3 studies available to analyze (Supplementary Table 5).

Sensitivity analysis

In a sensitivity analysis, repeating the analysis by rotating each study reporting associations to incident CKD from the same cohort of data one by one, there was no change to the primary finding for any lifestyle exposure, except fish intake, which became statistically significant when data from Haring et al (1) were substituted for those from Rebholz et al (2) (Supplemental Table 6).

A total of 6 studies reported unadjusted associations which can be seen in Supplemental Table 3. One study in the tobacco smoking and incident CKD (3) analysis and one for tobacco smoking and albuminuria (4) reported unadjusted associations. One study in the

physical activity incident CKD (5) analysis and one for GFR decline (6) reported unadjusted associations. We have completed a sensitivity analyses, removing these studies to test the robustness of analyses, where no change in the primary or secondary findings was observed. In a sensitivity analysis removing each of these studies from their respective analyses, the findings held robust on all four occasions.

Supplemental Table 2. Summary of the methods relating to data extraction, risk of bias, meta-regression and planned subgroup and sensitivity analyses

inter	est (s), reference exposure, study risks of bias, date of publication, line kidney function, duration of follow up, statistical analysis
	line kidney function, duration of follow up, statistical analysis
base	-
	and all and a structure of the same of the second and all
appr	paches (including adjustment for confounding variables), and all
data	relating to our primary and secondary outcomes. Binary outcomes
(inci	dent chronic kidney disease, end-stage kidney disease, eGFR decline
and a	albuminuria) were extracted as the most adjusted relative risks (RR),
odds	ratios (OR), or hazard ratios (HR). If data was reported in figures
and o	could not be located in text, Supplemental material or through author
conta	act, then we extracted the data directly from figures using Webplot
desig	ner (https://automeris.io/WebPlotDigitizer/).
Risk of bias Thes	e were further subdivided into five key question criteria; Selection
(repr	esentativeness of exposed cohort, non-exposed cohort,
ascer	tainment of exposure, and demonstration that outcome of interest
was	not present at the start of the study); Comparability of cohorts on
basis	of design or analysis; Outcome (assessment, follow-up length, and
adeq	uacy of follow-up); Selective reporting of outcomes; and other bias
Dose-response A do	se-response random-effects meta-regression analysis was performed
meta- base	d on the natural log of HRs for different categories of alcohol intake
regression (7, 8). There are four studies included in the meta-regression with at least
analysis three	quantitative exposure categories of the estimate HRs and their
varia	nce. Because each study used different units of alcohol intake
(gran	ns or number of drinks per day or week), we converted alcohol intake
in gr	am/day, by the formula alcohol (gram) = 1 drink*13g/drink, and the
med	an level of each category was assigned to each corresponding HR
(9).	If the upper bound in the highest category was not provided, we
assu	med that it had the same value.
Subgroup and To e	xplore the sources of heterogeneity, a priori subgroup analyses were
sensitivity cond	ucted exploring the type of ratio reported (risk ratio; odds ratio;
analyses haza	rd ratio). We also conducted subgroup analyses by country of study

origin, other health conditions, dose of alcohol consumption, baseline GFR, and length of follow-up. For outcomes where there existed multiple reports of the same outcome from the same cohort dataset, we conducted a study-by-study sensitivity analysis substituting included studies which reported associations from the same cohort dataset, where one study cohort is removed and another study reporting an association from the same cohort added in, with the process repeated until all studies from the same cohort dataset have been rotated through the meta-analysis once. Subgroup analyses are only reported for analyses where at least 3 studies are in each subgroup.

Bahadoran 2016	Tehran Lipid and Glucose Study (TLGS). Follow-up data from 2006/08 Healthy general population N=2,799 31 years 42.9% male 80.7 mL/min/1.73	Iran	Diet - Nitrite/Nitrate Captured using self-reported FFQ	5.8 years	1.	Incident CKD (<60 mL/min/1.73 m ²)	Age, sex, diabetes, hypertension, eGFR, and smoking, protein intake, fat intake, potassium intake and sodium intake
Bahadoran 2017	Tehran Lipid and Glucose Study (TLGS) Healthy general population N=1780 68 years 40.9% male 74.8 mL/min/1.73	Iran	Diet - L-Arginine Captured using self-reported FFQ	6.3 years	1.	Incident CKD (<60 mL/min/1.73 m ²)	Sex and age, BMI, smoking, serum creatinine, diabetes mellitus, hypertension, medications use, CVD, daily energy intake, protein intake, fat intake, and sodiumpotassium ratio.
Bahadoran 2017	Tehran Lipid and Glucose Study (TLGS) Healthy general population N=3052 40.3± 14.3 years 44.2% male 77.9 mL/min/1.73	Iran	Diet - Allium vegetables Captured using self-reported FFQ	6 years	1. 2.	Incident CKD (<60 mL/min/1.73 m ²) GFR decline (change at follow-up)	Sex, age, BMI, smoking, type 2 diabetes, TG to HDL-C ratio, physical activity, dietary pattern scores
Barbato 2019	Olivetti Health Study (OHS) Healthy general population N=637 51 years Gender NP 90 mL/min/1.73	Italy	Current smoker vs never smokers (independently of the number or smoked cigarettes per day) Captured on self- reported questionnaire	7.8 years	1.	Microalbuminuria (30mg/g to 300mg/g and greater that 300mg/g; 24-hour collection)	Unadjusted
Bash 2010	Atherosclerosis Risk in Communities (ARIC) Study Healthy general population N=15,324 54 ± 5.8 years 45% male 93 ± 21 mL/min/1.73	US	Current, former and never smokers Captured on self- reported questionnaire	16 years	1.	Incident ESRD or Death (ESRD (ICD 9 and 10 kidney transplant or dialysis); eGFR < 15mL/min/1.73m2)	Age, sex, race, gender, diabetes, BP, CVD, LDL, center
Bomback 2010	Atherosclerosis Risk in Communities (ARIC) Study	US	Diet - Sugar sweetened beverages	9 years	1.	Incident CKD (<60 mL/min/1.73 m ²)	Age, sex, body mass index, sodium intake, caloric intake,

	Healthy general population N=15,745 53 years 49.6% male 93.3 mL/min/1.73		Captured using self-reported FFQ				hypertension, diabetes, current tobacco and alcohol use, education, center, and race
Buja 2011	The Italian Longitudinal Study on Aging (ILSA) study Non-CKD elderly population N=1,542 65 – 84 years 92.7% male Baseline GFR NP	Italy	Alcohol consumption – Categories non- drinker vs, <12g/day, 12 to 24 g/Day, 24 to 47 g/day >48g/day Captured on self- reported questionnaire	3.5 years	1.	Incident CKD (<60 mL/min/1.73 m ²)	Age, education, antihypertensive, diabetes, blood, fibrinogen, TC, smoking, isolated systolic, HTN, lipid- lowering drugs
Chang 2013	The Coronary Artery Risk Development in Young Adults (CARDIA) study Healthy general population N=2,354 18 - 30 years 47.4% male 101.5 mL/min/1.73	US	Diet - Fruit; vegetables; wholegrains; nuts and legumes; low- fat dairy; sugar- sweetened beverages; red and processed meat; sodium; energy intake Captured using self-reported FFQ Currently smoking or not currently smoking Captured on self- reported questionnaire	15 years	1.	Microalbuminuria (sex-race adjusted urine ACR ≥25mg/g at 2 separate times)	Age, sex, race, family history of kidney disease, education level, baseline ACD and energy intake
Cirillo 2018	Gubbio Study General population (5.2% diabetes; 34.5% HTN) N=2,845 50 years 43.9% male 97 mL/min/1.73	Italy	Diet – protein (urine urea nitrogen)	15.9 years	1.	GFR decline (change from baseline to follow- up equal to or lower than Z-score of -1 (eGFR change < mean -1 standard deviation of eGFR	Sex, age, reduced kidney function, obesity, underweight, hypertension, hypercholesterolemia, smoking, ex-smoking, diabetes, previous CVD, urinary sodium/potassium ratio,

						change in the study cohort))	habitual physical activity, and habitual intakes of alcohol, milk or yogurt, and caffeine- containing beverages, baseline eGFR
Deriaz 2019	The Cohort Lausanne study Healthy general population (100% white) N=4141 51.5 years 45.7% male 88 ± 15 mL/min/1.73	Switzerland	Diet - Urinary sodium, potassium and sodium-to- potassium ratio Captured using spot urine collection using Kawasaki formulae	5.4 years	1.	GFR decline (change at follow- up)	Age, sex, physical activity, smoking status, diabetes, antihypertensive medication, SBP, BMI, triglycerides, uric acid, CRP, 25-hydroxyvitamin D
Dunkler 2013	The ONgoing Telmisartan Alone and in combination with Ramipril Global Endpoint Trial (ONTARGET) study T2DM N=6,213 67 years Gender NP 71.5 mL/min/1.73	US	Alcohol consumption – measured by the number of drinks/week, with 1 drink equalling 1.5 ounces of hard liquor or 1 glass of beer or wine. Diet - animal protein; plant protein; CHO intake; vegetable; sodium; potassium; fruit Captured using self-reported FFQ	5.5 years	1. 2.	Albuminuria GFR decline	Age, duration of diabetes, status of albuminuria, sex, ONTARGET randomization arms, GFR, and Δ-UACR to progression, BMI, mean arterial BP, glucose and previous use of angiotensin-converting enzyme inhibitors or angiotensin-receptor blockers, tobacco use, physical activity, and educational level to study the nutrition-specific effects of a healthier lifestyle and socioeconomic status.
Dunkler 2015	The ONgoing Telmisartan Alone and in combination with Ramipril Global Endpoint Trial (ONTARGET) study T2DM N=3,088 65 years 66.6% male 72.5 mL/min/1.73	US	Diet - Fruit, vegetable, fiber, protein, carbohydrates, trans fat, urine sodium, urine potassium Captured using FFQ (except sodium and potassium)	5.5 years	1.	Composite outcome (defined as new micro-, or macro- albuminuria, a decline in the eGFR of more than 5% per year or end- stage kidney disease)	Age, gender, duration of diabetes, ONTARGET randomization arms, albuminuria status, GFR and δ-UACR and UACR at baseline on the log scale, respectively

Ejtahed 2016	Tehran Lipid and Glucose Study General population (10.7% diabetes, 16.2% HTN) N=1,692 43.4 ± 11.4 years 43% male 70.4 ± 10.8 mL/min/1.73	Iran	Diet - Glycation End Products Captured using self-reported FFQ	3 years	1.	Incident CKD (<60 mL/min/1.73 m ²)	Age, sex, energy intakes, smoking, physical activity, body mass index, and sodium, diabetes and HTN
Esmeijer 2018	Alpha Omega Cohort Post-MI patients N=2255 69 years 80% male 82 ± 20 mL/min/1.73	Netherlands	Diet – Protein Captured using self-reported FFQ	3.4 years	1.	GFR decline (change at follow- up)	Age, sex, total energy intake, education, alcohol, smoking, physical activity, RAS blocking drugs, fat intake, dietary sodium, diabetes and systolic blood pressure
Farhadnejad 2016	Tehran Lipid and Glucose Study (TLGS) follow up data from 2006-2008 Healthy general population N=1,692 43.3 ± 11.4 years 49.2% male Baseline GFR NP	Iran	Diet - Micronutrient intakes (B1, B2, B3, B6, B12, folate, Vitamin A, C, D, E, sodium, potassium, calcium, magnesium, phosphorous, selenium, zinc) Captured using self-reported FFQ	3.6 years	1.	Incident CKD (<60 mL/min/1.73 m ²)	Age, sex, energy intake, serum triglycerides, serum cholesterol, BMI, hypertension, diabetes, physical activity, and smoking
Farhadnejad 2018	Tehran Lipid and Glucose Study (TLGS) Healthy general population N=1,797 37.7 ± 12.2 years 48% male 75.9 mL/min/1.73	Iran	Diet - Low CHO, high protein (CHO 51% compared to 64.1%; protein 15.8% compared to 12.9%) Captured using self-reported FFQ	6.1 years	1.	Incident CKD (<60 mL/min/1.73 m ²)	Age, sex, energy intake, serum triglycerides, serum cholesterol, BMI, hypertension, diabetes, physical activity, and smoking
Forman 2012	Prevention of Renal and Vascular End-stage Disease (PREVEND) Healthy general population N=4146 43.3 years 47.6% male	Netherlands	Diet - Urinary sodium excretion, 24hr collection	6.4 years	1.	Albuminuria (value at follow-up)	Age, BMI, sex, alcohol intake, smoking status, systolic and diastolic BP, GFR, plasma levels of glucose and cholesterol, and urinary levels of potassium,

	87 mL/min/1.73						calcium, and creatinine. Models were also mutually adjusted for baseline levels of serum uric acid and urinary albumin
	Framingham offspring study Healthy general population N= 1,802 59.9 ± 9 years 45.2% male Baseline GFR NP	US	Alcohol consumption - None (0 drinks/week); low- to-moderate (1–7 drinks/ week in women and 1–14 drinks/week in men); high intake (>7 drinks/week in women and >14 drinks/week in men) Physical activity - Physical Activity Index Smoking - Current	6.6 years	1.	Incident CKD (<60 mL/min/1.73 m ²)	Age, sex, eGFR, BMI, hypertension, diabetes and dipstick proteinuria, dietary guidelines adherence index
Foster 2015			≥1 cigarette/day in the past year Captured on self- reported questionnaire				
Fox 2004	Framingham Heart Study Healthy general population N=2585 43 years 47.3% male 112 ± 57 mL/min/1.73	US	Smoking - yes vs no Captured on self- reported questionnaire	18.5 years	1.	Incident CKD (<60 mL/min/1.73 m ²)	Age and sex
Gopinath 2011	Blue Mountains Eye Study Healthy general population N=2600 >50 years 43.2% male Baseline GFR NP	Australia	Diet - Carbohydrate intake Captured using self-reported FFQ	5 years	1.	Incident CKD (<60 mL/min/1.73 m ²)	Age and sex, serum total homocysteine, haemoglobin, and haematocrit

Gopinath 2016	Blue Mountains Eye Study General population (6.8% DM, 41.6% HTN) N=1185 64.1 ± 8.7 years 44.9% male Baseline GFR NP	Australia	Diet – Dairy and calcium Captured using self-reported FFQ	10 years	1.	Incident CKD (<60 mL/min/1.73 m ²)	Age, receipt of pension, BMI, smoking, serum triglycerides, HTN, and history of diagnosed diabetes
Halbesma 2009	Prevention of Renal and Vascular End-stage Disease (PREVEND) Healthy general population N=8,461 50 years Gender NP 80.6 mL/min/1.73	US	Diet – protein (24- h urinary urea excretion (Maroni formula) Captured using self-reported FFQ	6.4 years	1.	GFR decline (Change at follow- up)	Unadjusted

---	-----------------------	-------------	-------------	-------------	-------------	-------------------------------	------------------

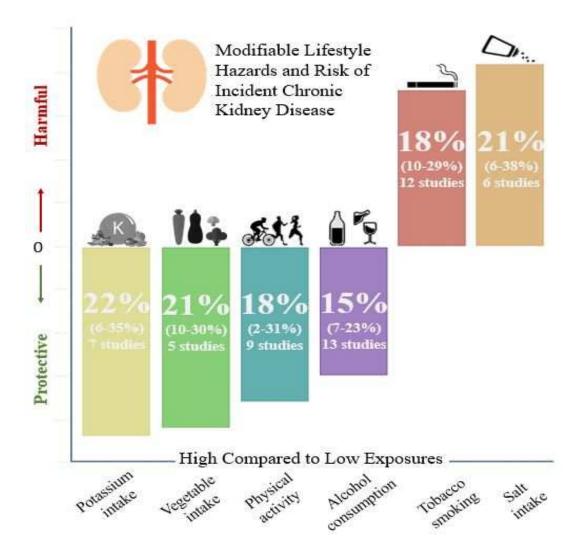

Abbreviations: CI: Confidence interval; OR: Odds ratio; RR: Risk ratio

Explanations

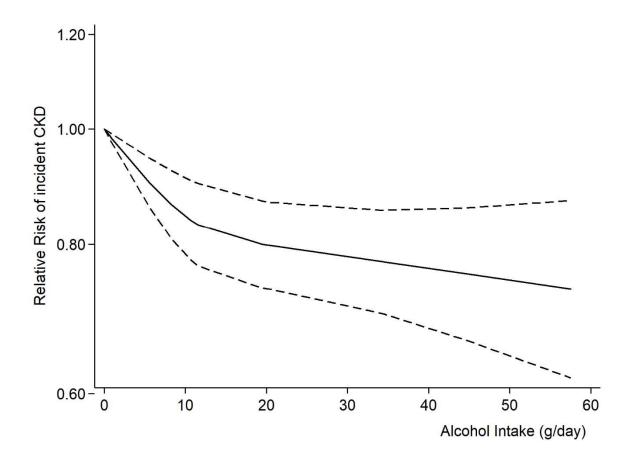

- a. Confidence intervals overlap
- b. Sample population not all general population and not all appropriate confounders adjusted for in primary analyses
- c. Moderate heterogeneity and confidence intervals overlap
- d. Outcome assessed in non-standardized manner across the included studies
- e. Very wide confidence intervals
- f. Moderate heterogeneity
- g. Unclear risk of bias across the studies for statistical analysis
- h. High heterogeneity
- i. High risk of bias for sample population, prognostic indicator and outcomes
- j. Less than 50% of studies conducted in disease free populations
- k. 2/5 studies conducted in diseased populations
- 1. High risk of bias across multiple domains

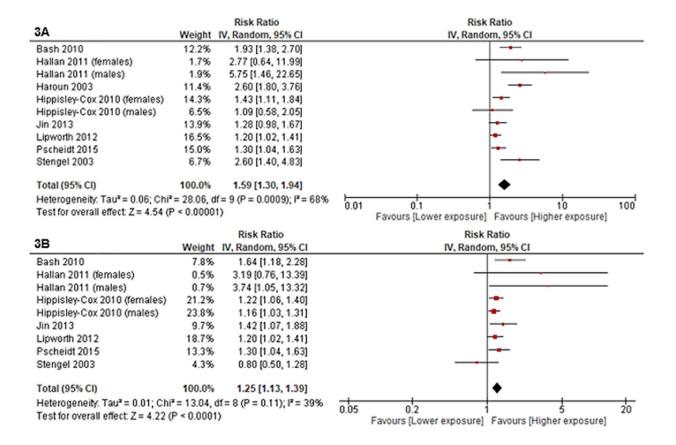

Supplemental Figure 1. Study flow diagram showing the selection of studies

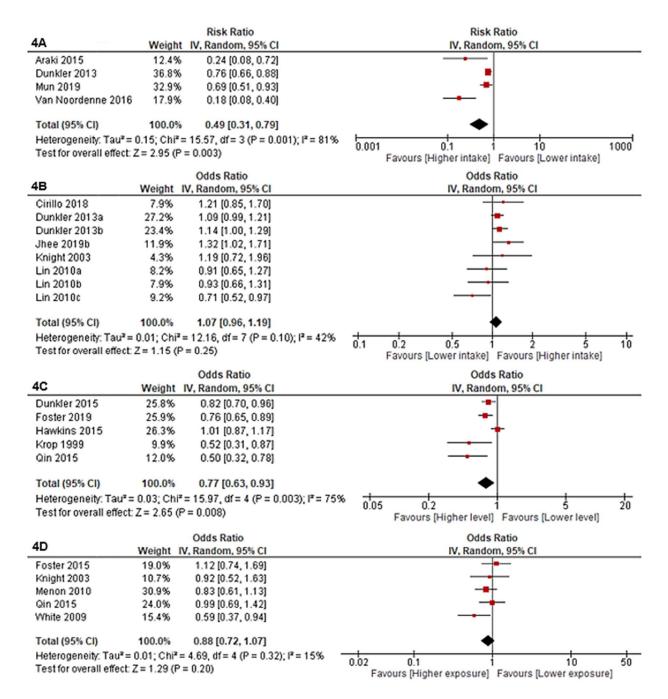

Supplemental Figure 2. Summary of the associations between modifiable lifestyle risk and protective factors and risk of incident CKD, based on observational evidence. The association estimate and 95% CI for each lifestyle factor are expressed as a percentage.

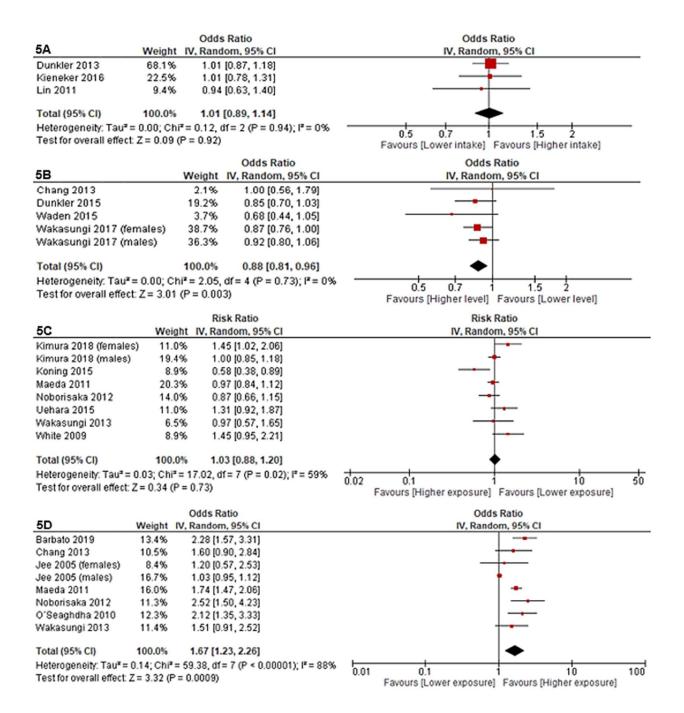

Supplement Figure 3. Dose–response relationship between alcohol intake (gram per day) and incident CKD estimated with a random-effect meta-regression-restricted cubic spline model. The dash line represents the 95% confidence limits for the fitted curve. P _{nonlinearity} =0.03.

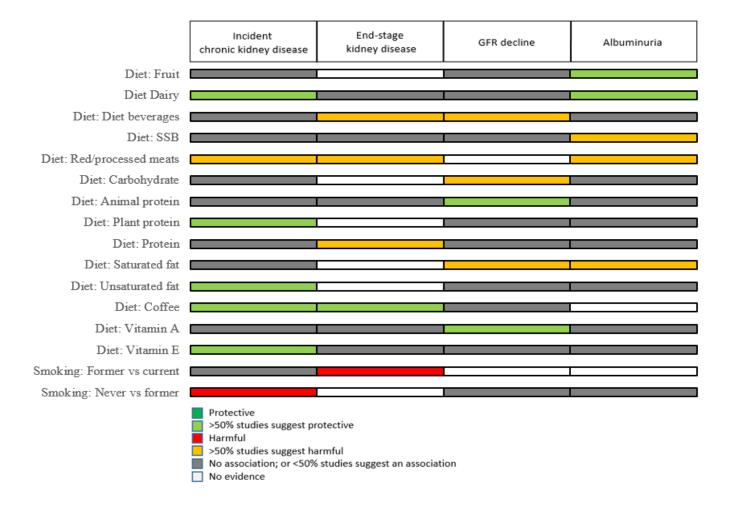

Supplemental Figure 4: Association of 3A Tobacco smoking (Current v Never), 3B Tobacco smoking (Former v current) and ESKD.

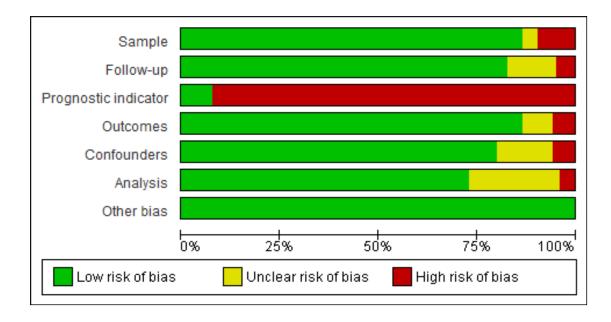

Supplemental Figure 5: Association of 4A Potassium intake, 4B Protein intake, 4C Physical activity level, 4D Alcohol consumption and GFR decline. Note the association estimate for each lifestyle factor is presented on the ratio (OR or RR) which was predominantly used in the included studies.

Supplemental Figure 6: Association of 5A Sodium intake, 5B Physical activity level, 5C Alcohol consumption, 5D Tobacco smoking and Albuminuria. Note the association estimate for each lifestyle factor is presented on the ratio (OR or RR) which was predominantly used in the included studies.

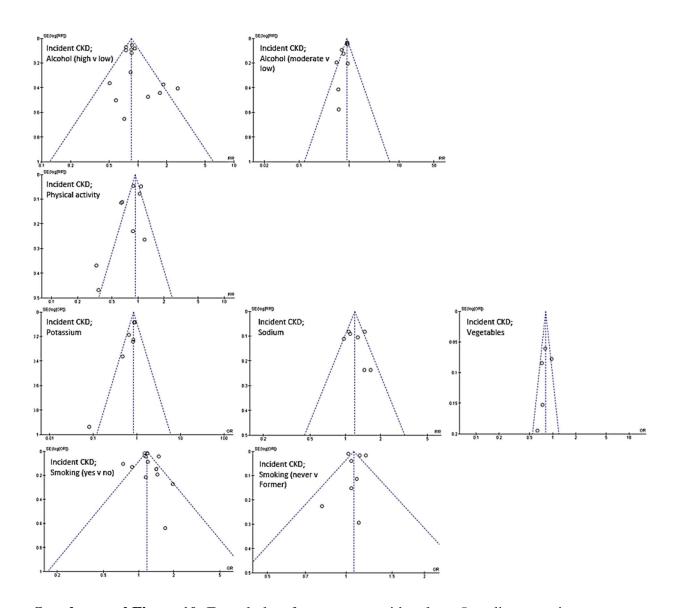

Supplemental Figure 7. Consistency of associations in lifestyle factors which could not be statistically pooled across the markers of kidney function decline. Summary of the number and proportion of studies showing protective and harmful relationships is further detailed in Supplemental Table 4.

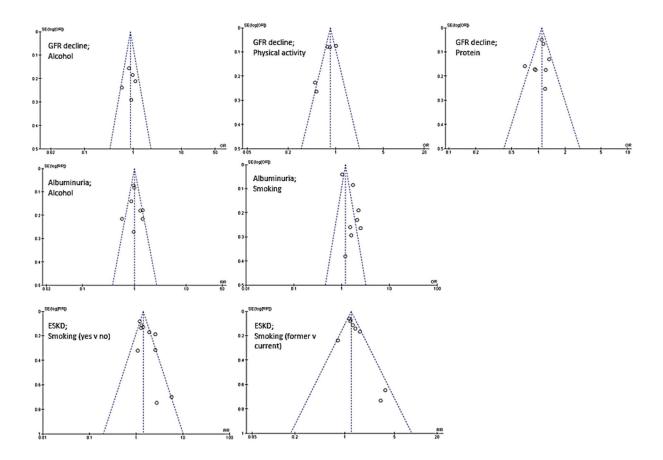

Supplemental Figure 8. Risk of bias across the included studies
