Supplemental Digital Content 3: Lifetime alcohol exposure percentile and recent log_{10} grams 30-day alcohol consumption are plotted against the probability of phenotypic frailty index classification severity. An effect display of the independent effect of (left column) lifetime alcohol exposure (LAE) percentile (%ile) or (right column) log_{10} grams 30-day alcohol timeline followback (TLFB) on phenotypic frailty index (PFI) classification probability is plotted above (n = 336). Regressed probability curves are adjusted for age and other covariates in an ordinal logistic regression of the extended covariate model. A test of the proportional odds assumption for ordinal logistic regression was upheld in each ordinal logistic regression model (Brant test p>.05).
